The results show that the participants' statements to a high extent correspond with the *relational discourse* found in the national steering documents. This was evident in statements stressing the importance of *vocational dedication*, a *positive attitude*, *good relations* and that *everyone (children, staff members, and parents) wanted to go to the preschool*, and noticeable in statements addressing the difficulty to define and evaluate quality. The teachers regarded themselves responsible for maintain good relations to the children and their parents, and to their colleagues. In this respect time is considered a crucial factor. The preschool teachers need time to meet each child and each parent, and time to facilitate the children's development. Within the *relational discourse* evaluations are performed by pedagogical documentation and collegial reflection. The *relational discourse* is to some extent challenged by the *NPM discourse*. This discourse was found in statements stressing a correspondence between activities and curriculum, and the local guiding principle: *perform, evaluate, and develop*. Evaluations are made by mandatory reports to the municipal administration and locally produced inquiry forms to the parents.

Our study indicates the coexistence of two differing quality discourses regarding Swedish preschools: I) The r*elational* discourse, closely related to the quality of the daily interactions between individuals (the preschool teacher, the children and their parents), and predominant in the national documents and in the participants' statements, and II) the *new public management discourse*, predominant in the local steering documents and detectable in the nationals documents and in the participants' statements. The results raise questions on how preschool teachers can handle the intangible nature of quality in relation to the demands for measurability and effectiveness raised by local politicians. Are preschool teachers required to quantify and measure the immeasurable? How will this affect the children, the preschool teachers, and the quality of the activities performed in the preschools?

INTRODUCTION

Historically conceptions of quality in preschools and other human service organizations have been formulated and maintained by the professional groups working in these organisations (Abbott, 1988). Quality has been closely related to the nature of the daily interactions between the professionals and the receivers of services produced in these organisations (Lipsky, 1980; Hasenfeld, 1983). The above implies that quality in preschools is created and maintained in the daily interactions between the preschool teacher or childminder and the children, which could be described as a relational discourse. However during the last decades a new concept of quality, emanating from market oriented organizational ideals often called New Public Management, has gained ground in human service organisations to such extent that it can be regarded a doctrine (Bejerot & Hasselbladh, 2002). In this new managerial quality discourse the professionals' conceptions of quality are often subordinate to market economic principles such as standardization, measurement and goal fulfilment. This discourse has influenced the formulation and evaluation of the human

sector organisations' objectives in such a way that is likely to bring about drastically changed working conditions for the professionals working in these organisations (Hasselbladh, 2002).

Swedish preschools are welfare institutions required to achieve and demonstrate high quality. The preschool teachers are responsible not only for the quality of the daily activities at the preschool, but also for the evaluation and development of these activities. The latter can be problematic especially in times of diminishing financial resources. This raises question on how quality is defined, maintained and evaluated in Swedish preschools.

The here presented study aims to explore *discursive expressions of quality and quality work among Swedish preschool teachers.*

BACKGROUND

The Swedish preschool originates from sociopolitical action plans formed during the formation of the welfare state in the mid 20th century. At the time the preschool's main function was to provide childcare in order to make facilitate women's accessibility to the labor market. Developmental and educational objectives were introduced several decades later (Tallberg Broman, 2010). Today preschool is a part of the educational system, whit its own curriculum, providing children in ages one to five years education and care.

Preschool quality in the national steering documents

The Swedish National Agency for Education (2005) underline the importance of developing municipal and local systems for monitoring and evaluating the effectiveness and quality, and thereby determine whether and how the activity meets the national provisions of the Education Act and the curriculum. The preschool staff (preschool teachers and child minders) are expected to participate in and have good knowledge the evaluation and assessment of improvements, to use various tools and methods to evaluate the activity's effectiveness, and to use the results of evaluations in the continuous improvements expected. This document also stress the difficulty to find methods appropriate for the evaluation of the complex educational processes in preschools (Swedish National Agency for Education, 2005).

The revised preschool curriculum Lpfö98 (Swedish National Agency for Education, 2010) dictate that the preschools are to provide opportunities for the children to develop competences in areas such as basic understanding of mathematical concepts, whereas content or didactics are not specified. Fulfillment of objectives, documentation and evaluation are further emphasized. These evaluations are to be focused on the preschool programme and the preschool teachers' performances, rather than the children's individual achievements. However research (Pramling Samuelsson & Sheridan, 2010) shows that contradictory to the curriculum, children's individual performances are measured and evaluated in a number of Swedish preschools. This suggests the existence of contradictions and ambiguities in the concept of preschool quality which indicates the need of further research.

Coexisting discourses in the national steering documents

An analysis of three contemporary national steering documents for the Swedish preschool: *The government proposal for a new education act* (Prop. 2009/2010:165) where the chapter concerning pre-school is analysed in particular; *Quality in pre-school*, which forms guidelines for pre-school activities (Swedish National Agency for Education, 2005); and *Proposal for clarification of the curriculum for pre-school* (Swedish National Agency for Education, 2009) (Tullgren & Österlind, 2010).

Communal for the analysed documents was the strong enforcement of goal fulfilment, evaluation and documentation, and the pre-school teachers' general significance to and responsibility for the quality of the activities performed in the local pre-schools. However the analysis reviled a shift in the prevailing discourses of quality work in pre-schools in general and the pre-school teacher's role and responsibility in particular. In the documents from 2005 and 2009 the pre-school teachers are construed along with the ideas of Schöns reflective practitioner (Schön, 1983), quality is to be achieved and ensured through collegial discussions and reflection, and quality work is construed as a mutual concern for the pre-school teachers and other professional groups. Whereas in the document from 2010 the pre-school teacher is re-construed into someone who can be described as a New Public Manger (Denhardt & Denhardt, 2007) ascribed responsibility for planning, execution, evaluation and development of the activities in relation to the goals set in the curriculum, facilitating parent and child influence on and participation in the quality work.

In summary our analysis of the curriculum and other national steering documents showed two coexisting discourses concerning quality and quality work in Swedish preschools: I) a *relational discourse* within which quality was closely related to relations and reflections, and II) a *new public management (NPM) discourse* within which quality was related to measurability and effectiveness.

Preschool quality in earlier research

According to Haugs (2003) overview of Swedish research on quality in preschool the field is dominated by contradictions between different approaches where the main features is to coexisting discourses- quality as objective and quality as subjective.

Coexisting discourses in research

In an objective discourse quality is considered unambiguous and possible to measure and to achieve. Within this discourse tools for measuring is an issue, whit the right tools quality could be detected and achieved. An example on such tool is Early Childhood Environment Rating Scale (ECERS), an instrument for observing and forming an estimate of certain content in relation to goals for the preschool program. Sheridan (2001, 2009) is one example on a study where quality was evaluated using this scale (ECERS). The results shows that staff in preschools whit low quality on the rating scale tended to overestimate them self, while staff in preschools whit high quality tended to estimate them self lower.

An example on the subjective discourse is the research of Moss and Pence (1994) Here quality is considered as related to the situation and the context in which it is used. Quality is, so to speak, "in the eye of the beholder" (Moss & Pence, 1994, p. 172). This discourse has its origin in social constructivism and preschool context is considered as constructed by teachers and children and thereby quality is depending on the individual preschool and how it is constructed. By pedagogical documentation (Dahlberg, Moss & Pence, 1999) where the teachers document and analysis of a certain activity, leads to a common point of departure for (self) reflection and for construction of the preschool.

METHODOLOGY AND METHOD

Earlier studies have contributed whit definitions of quality and have given purposes on how quality could be achieved and measured. I this paper we focus on such expressions and study how this discourses express them selves, in i.e. statements of preschool teachers claiming, to be true (Foucault, 2002). For that purpose we use the methodological framework is inspired by Foucault's theories of discourse and knowledge relations (Foucault, 1982; 1993), in which discourses are regarded as more or less systematic statements about how we should think about the world (Foucault, 1993). According to Foucault discourses are related to (scientific) knowledge production, and it is the knowledge considered as the truth that forms discourses. Discourses lead to mechanisms that control individuals by construing some manners of speaking and behaving as approvable, true and good, while others are construed as false, untrue and reprehensible (Foucault, 1993). Hereby the study of discourses is closely related to the study of power relations, focusing on how these relations are operating in how people talk (Foucault, 2002).

Data was collected during a seminar where 38 preschool teachers discussed the questions: 1) What is quality in preschool? 2) How/where/when does quality become visible? 3) How can quality be achieved? 4) How can quality be evaluated? The preschool teachers where given the questions one at the time. Each question was discussed in pairs for a few minutes, where after these answers were ventilated in the lager group. Tullgren and Österlind were present during these discussions. Tullgren led the discussion and Österlind took notes on the white-board. These notations form the data of the here presented study. This perspective is used to illuminate the discourses that operate when the preschool teachers discuss quality in preschool.

The analysis showed that the *relational discourse* was predominant in the preschool teachers' answers to question 1 [What **is** quality in preschool?], and ... in their answers to question 2 [How, when and where is quality attained?]. The relational discourse is also present in their answers to question 3 [How can quality be achieved?]. While the in question 4 and 5 the manage discourse appears parallel to the relation discourse.

RESULTS – PRESCHOOL TEACHERS' TALK ABOUT PRESCHOOL QUALITY

The analysis show that the preschool teacher participating in this study express a relational discourse in which he children's wellbeing and security forms the basis of the preschool teachers' work and conceptions of quality. Within the relational discourse preschool quality is closely associated to interpersonal relations. Quality, in its widest sense, is achieved when all parties (parents, staff and children) are "feeling fine" and "want to go to the preschool". The preschool teachers make themselves responsible for the wellbeing of all parties. They also make themselves responsible for creating and maintaining the good relations (to children, parents and colleagues), which are regarded essential to the quality in their respective preschools. This relational discourse is to some extent challenged by a coexisting discourse.

Preschool quality within the relational discourse

The relation discourse was evident in statements stressing the importance of *vocational dedication*, a *positive attitude*, *good relations* and that *everyone (children, staff members, and parents) wanted to go to the preschool* and *awareness of the importance of relations and the relationship* are mentioned by the preschool teachers as important for quality in preschool.

Initially the preschool teachers state that quality is difficult to define and measure, however the correspondence between activities and curriculum is highlighted. Quality is also considered relative in the sense that conceptions of quality can vary between individuals and/or interested parties such as children, staff, parents, local government officers and politicians. However the following statements show that the preschool teachers have clear conceptions of preschool quality.

According to the statements the preschool teachers' relations to the children are crucial for the teachers' possibilities to support the thriving and development of each child in accordance with her or his individual needs and requirements. Quality is manifested in the children's positive reactions and joy, but also in their individual development which is denominated developmental steps. The preschool teachers make themselves responsible for forming an opinion of and meeting each child in accordance with his or her conditions and provide appropriate challenges. In this respect time is considered a crucial factor. The preschool teachers stress the necessity of having sufficient time to follow the development of the children. Quality is attained in the relation between the preschool teachers and the children, when the different activities and skills contribute to the children's development. In this sence, the preschool teachers' personal attitude was considered of outmost importance. The preschool teachers' relations to the parents are considered essential for the children's wellbeing. The preschool teachers find it necessary to cooperate with the parents in order to prevent the children from being caught in the middle between preschool and home. In this respect it is also important that the parents feel confident in leaving their children at the preschool.

The preschool teachers' relations to their colleagues are considered vital since quality is evaluated through collegial reflection at the team meetings. Personalen som arbetar på förskolan skall ha för ändamålet adekvat utbildning. Professional harmony among the teachers was very important and influenced the recruitment of new colleagues. Good collegial relations are also important to the preschool teachers' personal wellbeing.

Quality is evaluated through pedagogic documentation and by the preschool teachers' collegial reflections at the staff meetings. The child's development is to be highlighted in the pedagogic documentation. Child interviews can form the basis for further evaluations. Evaluations are performed by pedagogical documentations and collegial reflections. The children's expressions of *pleasure and joy* are seen as quality parameters and are reported as well as their development. It is desired that both the children and their parents participate in the evaluation process for examples through child observations and questionnaires to the parents.

The relational discourse is challenged by a management discourse

The analysis shows that the relational discourse to some extent is challenged by a management discourse. These challenges were evident in the preschool teachers' statements regarding quality audits, evaluations and other comprehensive reports induced by the national and local authorities. These pose a threat to the prevailing concept of preschool quality within the relational discourse, since they represent a market oriented concepts of quality. These threats are handled by the production of local questionnaires to the parents in addition to the mandatory ones.

The challenges to the relational discourse are also evident in the preschool teachers' statements regarding staff cuts and increased numbers of children induced by financial cutbacks.

These posed a threat to quality by adding to the preschool teachers' time shortage and hereby obstructing them from giving every child the attention vital to his or her development and wellbeing. The statements imply that this threat is more difficult to handle within the quality discourse. However the preschool teachers try to carry out necessary actions in such a way that the negative implications for the children, and the preschool teachers, are minimised.

DISCUSSION – ARE THE SWEDISH PRESCHOOL TEACHERS IN A DISCOURSIVE CROSSFIRE?

This study indicates the coexistence of two differing quality discourses regarding Swedish preschools:

    I)   The r*elational* discourse, closely related to the quality of the daily interactions between individuals (the preschool teacher, the children and their parents), and predominant in the national documents and in the participants' statements, and

II) the *management discourse*, detectable in the nationals documents and in the participants' statements.

The discourses visible in this study both have their origin in ideas about how quality could be achieved in welfare institution. The *relation discourse* however could be described as a traditional welfare discourse whit it's origin in the professionals definitions of quality as something which is to be observed in the good meeting(-s) between individuals (Lipsky, 19xx; Hasenfelt, 19xx). This two discourses are visible on a society level, not least in national steering documents (Tullgren & Österlind, 2010). *The Management Discourse* is to a minor extent present in the talk of the preschool teachers in this study. Only when it comes to measuring quality they show awareness of it's existence. They mention that evaluations of the work in preschool are seen as comprehensive reports to the municipality and often follow local, regional or national evaluation plans or schemas. Evaluations are made by mandatory reports to the municipal administration but do not maintain the discourse. The preschool teachers express strategies to cope whit such external demands at the same time continue the quality work in a relation orientated way, on a local level.

The results indicate that the two discourses operates in the same time and that the preschool teachers have to handle them both. They do that by adopting the relation discourse and by when the preschool teachers meet the management discourse, they handle those challenges so that the relation discourse not will be threaten.

The results also indicate that the preschool teachers in this study have experienced diminished financial resources in their local preschools, together whit impressions of the management discourse could forces the preschool teachers to modify their way of working in accordance with the new financial situation in such a way that it could have effects on the quality in the local preschool (Hasselblad, 2002). This could be seen as adjustment to circumstances rather than countermeasures (counterfire). It could also be understood as a strategy to be left alone and do the work as good as they can under the circumstances being. Left alone in the meaning of being allowed to work in the same way as they have done in "the good old days" although it is hardly impossible .

The results raise questions on how preschool teachers can handle the intangible nature of quality in relation to the demands for measurability and effectiveness raised by local politicians. Are preschool teachers required to quantify and measure the immeasurable? How will this affect the children, the preschool teachers, and the quality of the activities performed in the preschools?

Abstract: This research aims to analyze the trajectory of Teaching Practice, Teacher Training, ascertain the routines established in the guidance training process and indicate the challenges that emerge of guidance process in training and initiation to teaching, considering the manifestations by teachers, trainees. The research is qualitative and techniques are: research literature, semi-structured interviews and content analysis. Initial results show: the Teaching Practice and Teacher Training were understood as discipline and activity with emphasis in activity. Trainees has insecurity in first contact with children – how to act in the classroom; concern with a school team without guidance about the learning profession process and questioning of supervision received in school. The mentors have the trainees as helpers, not how to future teachers, present challenges in relation to procedures used in supervision. In this first stage of the study we proved the necessity of to value school as a locus of training.

Keywords: teacher education, teacher training, school, Pedagogy.

INTRODUCTION

The concern with teacher education began in Brazil after the Reform of Primary Education (1890), adding events such as the incorporation of the Didactic Course (1939) Subjects Pedagogical (Brazil, 1962, 1969) until the proposal of a Body of Knowledge and Teaching Practices (Brazil, 1939, 1962, 1969, 2002a; Minister of Education and Culture, 1996) and Magisterium Universitarization (Minister of Education and Culture, 1996).

In this context, the Teaching Practice and Supervised Training gained ground in the training process. Transiting between challenges to be understood as an activity and / or as a discipline, currently, has distinct roles in which the first was transformed into practice as a Curricular Component, while the other was restricted to Supervised Training. However, the issue of training has a dual interpretation: of one side it is seen only as an activity, testing or training, while the other it is intended as a discipline, field of knowledge (Brazil, 1997, 2002a, 2002b; São Paulo, 1997), having the first understand as hegemony.

Thus, in initial teacher education, Pedagogy course, you find some battles with regard to the Teaching Practice and pre-service training, for example, the national policy for training of trainers which not expected formally a responsibility of schools in didactic and pedagogic training of future teachers neither the preparation or orientation of the experienced practitioner (mentors) who guide these trainees (Brazil, 1946, 1962, 1969, 1977, 1982, 1984, 1993, 1994, 1997, 2001, 2002; Minister of Education and Culture, 1996).

In this context, the training law (Brazil, 2008, 1994, 1984, 1982, 1977) have been presented general and limited about teacher undergraduate courses, because despite of advances presented, there are emphasis at the compulsory training (or curricular), and not compulsory, at legal regulation in the field of labor in industry, factories, etc., creation or not of employment leaving the didactic-pedagogical aspects background.

In the case of teacher undergraduate courses, not it enters into the perspective of valuing of school environment, mentors preparation, the professional insertion and monitoring of new teachers in the first year out of university. Therefore, there are gaps in the constitution of professional teaching, leaving to be desired with regard to "the qualities of teachers professional practice according to the educational work requires" (Contreras, 2002, p. 74), as well as of own process of training when refers pre-service training with in Pedagogy courses:

> What was seen in the analysis of projects and descriptions of courses, it is that there is no plain specification about how they are conducted, supervised and monitored. About the validity or validation of these stages also did not find any reference. The aims are not comprehensible, neither the requirements, forms of validation and documentation, monitoring, partnerships with schools etc. This absence in the projects and discipline program may signal that are either considered completely

separate from the curriculum, which is a issue, as it should be integrated with the training disciplines and aspects of education and teaching, or its implementation is considered as merely formal aspects. A more detailed study, location, about the teacher training should be conducted (Gatti & Nunes, 2009, p. 21)[90].

In this context, what is the pre-service training and teaching practice? What role the responsibility of the university and the school? What makes mentor's Elementary School which receives and monitors the trainees? How are they selected? How do they guide the trainees?

Therefore, considering the issues raised and the issues presented, this study investigates how to develop the Teaching Practice in pre-service training in a Pedagogy course, public university of São Paulo state, using as participants the trainees and mentors. How specific aims the research analyzed the trajectory of Teaching Practice, Teacher Training, ascertain the routines established in the guidance training process and indicated the challenges that emerge of guidance process in training and initiation to teaching, considering the manifestations by teachers, teacher students and school in this process.

In this exploratory study, it was decided to for qualitative research (social constructivism) having as techniques the research literature, semi-structured interviews and content analysis. Selected arbitrarily 20 participants: 10 trainees with compliance all obligatory practical training, and 10 mentors experienced practitioner (mentors) who received trainees in their classroom. All participants signed a consent form approved by the Ethics Committee. The results were organized into two major blocks, one related to primary and secondary sources and the other linked to field work.

THE TEACHING PRACTICE AND SUPERVISED TRAINING

The Teaching Practice and Pre-service Training in Brazil

The issue of internships in Brazil, gained emphasis during the XIX century with the reforms of primary and secondary education (1890 and 1946), which revealed gaps in the preparation of teachers and presented as alternative an practice-oriented teaching to trainees in Normal Courses (1939) and in Application Gymnasiums (1946). Therefore, in the XX century begins with a critique of Didactics, questioning the Teacher Education.

From this moment, between critics of didactic and school, the training was restricted to point, just, the gaps of the school, teachers, principals etc., and they are no longer welcome at school. In this process, it created a gap between university and schools, conferring to the Secretary of Education's role to force them to receive trainees (Pimenta & Lima, 2004).

On this journey, other changes occurred as the Parecer 292/62 (Minister of Education and Culture, 1962) that established a teacher education oriented "what to teach" and "how to teach" and the inclusion of Teaching Practice as a pedagogical discipline in predisposed LDB 4024/61 (Brazil, 1961).

Hence, the term Teaching Practice (Brazil, 1962) from the ancient Special Didactics (Brazil, 1939; Bicudo, 1995), was established by public policy, aiming to approach the reality the student to the pedagogical reality of schools with respect to the experiences of teaching, going to be done within the template observation, participation and conducting.

Observation was understood as a period in which the student-teacher watched the class teacher. Participation was seen as a moment when the trainee aided in didactic activities in classroom and Conducting was restricted the time that the trainee gave the class, taking the classroom (Faria Jr, Corrêa & Bressane, 1982). Besides those roles or strategies, there were other possibilities involving monitoring arrangements like a refresher classes or students with learning difficulties; minicourses, internship proposals from emerging themes, etc. The internships could be developed individually or in groups of two or three trainees. In this context, there was also the idea the supervision be performed by a qualified teacher, with the aim to avoid some gaps that trainees committed during the process.

Thus, this kind of Teaching Practice / Supervised Training has incorporated their understanding of two concepts: discipline and activity. As *discipline* dated back to ancient Special Didactics, performing as "Teaching Practice" may incorporate both the Methodology of Teaching and Supervised Training, while as *activity* was restricted to the planning and implementation of the "Supervised Training" (Faria Jr, Corrêa & Bressane, 1982).

With these thoughts, Pimenta & Lima (2004) accentuate that the internship model presented to the trainees gave priority to the concept the Teaching Practice as an imitation of existing theoretical models and efficient

---

[90] All citations in this paper are free translation.

to teach only those children who had the appropriate conditions for learning, starting to be understood by some Elementary and Secondary Schools with mistake because "the practice was only a theoretical application" (Oliveira, 2006). Therefore,

> The absence of an course project integrator caused situations from the underestimation of the presence of the trainee in school, as the destination of him to comply only manual tasks and bureaucratic, including: sharpening pencils, play in mimeograph copies of tests, follow students to the bathroom ... (Oliveira, 2006, p. 19).

With the new LDB[91] 9394/96 reaffirmed the importance of internship proposing for all the Teacher undergraduate courses the Teaching Practice with at least 300 hours, being changed in 2002[92] with the proposal 400 hours of Supervised Curricular Training, from the second half of course, with the mandate to be a learning period the profession to be exercised in the future (Brazil, 2002a, 2002b).

In this new format, thought about teacher education from a body of knowledge: knowledge, skills and abilities, teaching practices, bringing as innovation the displacement of the axis of the qualification for professional certification and with regard to "Teaching Practice" this has been thought from the perspective the "Practice as a Curricular Component".

This way the Resolutions CNE/CP nº 1 e 2 (2002a, 2002b) brought changes to the courses, having as a final proposal for an undergraduate curriculum of at least 2800 hours, including the possibility of a alternance training with 800 hours, divided in 400 hours of Supervised Curricular Training and 400 hours of Practice as a Curricular Component. In this direction, the Teaching Practice was seen as teaching practices or pedagogical practices of the Practice as a Curricular Component, because it is "a practice that produces something in teaching".

Regarding Supervised Curricular Training, this came to be guided by Law # 11.788/2008 proposing in Article 1º that the internship is "the educational school supervised (...) which aims to prepare for the job " and in paragraph 2º that it aims to own learning skills of professional activity (Brazil, 2008), introducing a higher organization between the educational institution and part of the conceding internship.

However, for some researchers on this subject, the internship is to: (a) purpose - to approach the reality in which the trainee will work, can also be seen as a place of reflection on the construction and strengthening the teacher identity (Pimenta & Lima, 2004); (b) aim - to smooth out the shock of transition the student life to the life of teacher-beginner, seeking to benefit a better assimilation of the subjects in the curriculum (Menezes & Santos, 2002) and; (c) goal - "bringing the student closer to reality in which to act, taking care not to situate the training as a practical moment of course, but as an approach to practice" (Costa, Guarnieri, Monteiro & Ribeiro, 2007, p. 86).

Thereby the training is part as a building of teacher education connecting and keeping the unity of theory and practice developed not only by student teachers, but also with the participation of professors (university) and mentors.

The mentors as a teacher trainer

In today's society, the teacher is seen as responsible for the construction the "Society of the Future" (Nóvoa, 1999), placing expectations on the projection of an ideal teacher, or in what, that…

> should know your subject, your discipline and your program, in addition to having some knowledge of science education and pedagogy and develop a practical knowledge based in their daily experience with students (Tardif, 2002, p. 39).

In fact, the school teacher is seen as a trainer of students, but forgets that he also receives trainees in your classroom and becomes a teacher trainer. Therefore, the teacher carries the daily practice being of great importance in transmission of knowledge to teach trainees, because the more significant is the guidance given to the trainee, and the relationship between them, the better their development as future professional.

Borges (2008) reflects this possibility when explain the experience with mentors in Quebec / Canada, noting that these are seen as associated teachers, taking on responsibilities for the training of trainees in the process internship and awakening in students a greater involvement with teaching.

---

[91] LDBEN - National Education Bases and guidelines Law (Minister of Education and Culture, 1996)
[92] Resolutions CNE/CP #1 and # 2/2002.

In Spain, Garcia (1999b), to elaborate on the procedures for monitoring the internships, from the studies of Pérez Gómez (1992a), emphasizes two aspects with regard to guidance given by mentors: one traditional and one focused on reflection on practice. In the first,

> teaching practices are conceived as an initiation process whereby the mentor teaches to the student a set of skills attitudes, personality traits and, in definitive, his own teaching style, which is assimilated by the students through observation, imitation and practice directed (p. 40).

For the author, this conception guidance, do not permit the trainee that the perspective of teaching goes beyond that observed, being a passive learning of teaching, because for teacher "their 'know-how' is enough to consider that 'knows how to teach'" (p.41). With respect to guidance on reflective practice, the author indicates the need to train reflective teachers, or, to have practice guidelines and know how to relate between the universe of school and university, avoiding to the reproduction and / or passivity.

In Brazil, there is no national policy for training of mentors, only local initiatives and tacit agreements, guided by a social-affective dimension that tries to meet the needs linked to the internship process. However, it does include the issue the traditional guide or reflective, or, several behaviors that can be witnessed at moment of the internship, such as the relationship between trainees and teachers in this study.

The Elementary School as a locus the Initial Training

The Elementary School is conceived as an education area for students aged between six and 17 years, comprised of three steps Childhood Education, Elementary and Secondary Schools (Minister of Education and Culture, 1996). It provides full education to these individuals, with the aims: "develop the students, give them the common education indispensable for the citizenship and provide him with the means to progress in work and studies." (Minister of Education and Culture, 1996).

The school is a place for exchanging experiences between students, teachers, directors, employees, and in this environment there is the possibility for all who participate in learning (Tardif, 2002). In this context the Elementary and Secondary Schools is a scenario of teacher training, however, this training will be significantly enhanced in the in-service training.

However, while initial teacher education, usually the school is not viewed the same way, although there are perspectives that recognize it as a place of contributions to the trainees as noted in Fontana (2000) mentioned by Ferreira (2005) to affirm that although the schools deal with teaching, do not teach who work in them (especially teachers in beginning of career) (p.36). These need the school environment to learn and understand the teaching profession.

From the development of curricular internship not only the trainees are in the process of education, but also the mentors are part of this action with the exchange of knowledge and experiences that happen in this practice. In this way, it is worth mentioning that besides the school give place to the realization of stage, should also contribute to the education of this trainee.

However, the school formally is "pulling" for the training of trainees, which will be their probable future professionals (Kist, 2007, p. 34). Thus, it is necessary that the training institutions and primary schools have clarity about the profile of teacher wishing train. (Terrazzan, 2000 *apud* Kist, 2007).

THE TEACHING PRACTICE AND SUPERVISED TRAINING IN SCHOOLS: TEACHING IN THE PERSPECTIVE OF THE MENTORS AND THE TRAINEES

The transcriptions achieved from interviews with 20 participants, 10 trainees - student-teacher (AMs) of the Faculty of Education in 2009 - and 10 mentors (PCs) - experienced practitioner, of the municipal schools - were organized in themes and developed the following topics.

Participants

The AMs constitute a diverse universe in which: three work in education as school monitors (AM-I, AM-V, AM-IX); two trainees work (AM-II, AM-III) at university projects related to education for youths and adults, youth, sexuality and violence in suburbs; two (AM-II and AM-X) teach at an institution of non-formal education; one (AM-VII) teaches foreign language at a particular institution of formal education and two (AM-VI, AM-VIII) do not work in education.

The PCs were differentiated in the time of teaching: six (PC-I, PC-II, PC-IV, PC-V e PC-VII e PC-VIII) have 20 years of teaching and one (PC-VI) teaches for 11 years, all they have gone through the normal course and pedagogy and they are at the stage of diversification of the teaching career (Huberman, 1995); other PC (PC-III) has four years of teaching, went through the same path of training of their colleagues and

is on stabilization stage of the teaching career (Huberman, 1995). However, the last two, PC-IX e PC-X, did not comment about the issue.

The stages of the teaching profession give indications of the trajectory of professional life, should not be seen as something static and unchangeable, because it is flexible in its configuration proposed by Huberman (1995), and it is worth this group, three (PC-I, PC-IV e PC-VIII), in their 20 years of teaching, had a training at the university to receive trainees, conducted by professor linked to the discipline of Teaching Practice.

In mentors' look about teaching in the present and past
In reviews performed about the internship process, the PC indicated some elements that they considered necessary for the development of the internship: contact with students in the class and the routine; the participation of trainees in class; to know reality of school and interaction with the classroom teacher; the trainee must question and feel as a teacher; learning each other, other words, exchange of experiences; to analyze the practice of another teacher and integration between university and school for the training process happens so successful.

Among the comments shown on guidance to the trainee was noted:

> *so that we can help trainee as classroom teacher, (...) this trainee will need to be able to ask your doubts and also to do her part. (...) I see as an indispensable this **link between the school teacher and the trainee**, and in this environment of cooperation, collaboration, mutual learning* (PC-I).
> *I guess indispensable for the trainee to actively participate in class, integrating with the teaching process, with students, because the experience comes with practice. In theory it is easy to lead a classroom but in day to day is that you really perceive the difficulty of the work* (PC-IV).

Therefore, is valued the interdependence at the same time it shows the knowledge of experience. However, it was also registered that in the context of these guidance given by the PCs, the AMs could be seen more as auxiliary of class or be guided only when they need *"I talked a lot with her (...) she helped me (...) brought the her little class prepared, more or less as it was in my time, I helped her (...) if she needed"* (PC-V); *"(...) I guided very little in reality they were who had more interest (...) the majority already well prepared"* (PC-II). Or…

> *(...) when they ask for opinion, I guide (...) and when they do not ask, they are just sitting there in the background, I come in and say: 'You do not want to help me here (...) you do not want to give him a little help here'* (PC-V).

We can observe a guidance perspective that resembles one of the aspects presented by Garcia (1999a), the traditional, saved in due proportion, because the tonic is to learn by observation and experience. However, there was some guidance more reflective (Garcia, 1999b), pointing to the dialogue, experience in the classroom, exchange of experiences, integration between teacher and student-teacher in the accounts of PCs (PC-I e PC-IV, PC-VI, PC-VII e PC-VIII): *"had this moment of integration the trainee with class (...) we would take away the doubts (...) always talking, exchanging what we thought, what we felt, then, always talking"* (PC-I); *"First they need to experience a classroom (...) guidance comes from the doubts and questions which emerging during this training and the harmonious relations among teacher and trainee"* (PC-IV); and *"it is more talk colleague to colleague (...)it is an exchange of experiences. (...) she came with one thing and I exchanged experience with other"* (PC-VII).

With regarding the perspective of training, how these teachers were trained or how they tried to train the trainees, the accounts showed the issue of teaching and way of conceiving the profession.

In opinion of these teachers, the teaching profession has many challenges (PC-VI), because there is the needs to have love for what you do and not think about the salary (PC-II, PC-III e PC-VII); to be patient (PC-I e PC-II), to be calm, to do research before making a decision (PC-I); know how to work with diversity and to be human (PC-VI); be "strong with the students", but also to do the role of educator, mentor and friend (PC-V); concluding with the view that this practice is viewed as a rewarding experience, requiring planning, action and reflection (PC-III).

The accounts show the characteristics that are present in the socialization of the professional world with the school, valuing the knowledge of experience, morals of good customs, the affective dimension of educational act, finally, the humanization process which involves education. In this way, Sarti (2009) makes a counterpoint with university noted that it is not offered by the training institution, because this type of learning does not take a "significant place inside the training instances as the university" (p. 140).

> (...) from one side by the specificities that distinguish the university teaching and teaching profession in the early years of schooling and, from the other side, the student position from which students understand the teaching profession during this period of institutional training (Sarti, 2009, p. 140).

Thus begins at the moment the training, the transition of student to teacher, merging the rites of students, the representations of the office of student and artifacts of the teaching profession. In this transition, the PCs look to the AMs with a double eyes that includes someone who is in training and that has in her genesis of be a teacher: *"(...) they are also teachers (...) they are still studying (...) the teacher and the trainee are on equal footing " (PC-I).*

Therefore, in the list of experiences which were considered important in the transition of student to teacher, the PCs mentioned as significant aspects: have empathy, respect, kindness and sharing of experiences (PC-IV); learn with other (PC-VII) and merge the concepts of practice and theory (PC-VI). Thus, the PCs, in the guidance to AMs, rely on the knowledge of experience (Pimenta, 2002; Tardif, 2002) as the source of their social knowledge which follows one prescription invisible related with the exercise of professional teaching (Contreras, 2002), but without the density which this requires. Are mentors which love what they do, but who tend to follow a "tradition" and can teach or guide the same way they have been taught (Goc-karp & Zakrajsek, 1987).

Regarding the issue of the formation of AMs in the training process, the PCs indicated as a limiting factor of their work, lack of the teacher time (PC and PC-I-VI). About to receive training to guide this process, they demonstrated to be unnecessary to do preparatory courses (PC-I, PC-V, PC-VI e PC-VIII), but there was recognition of the need to have a initial meeting to explain the objectives of the student training (PC-I e PC-VI), as well as the teacher to be notified before receiving the trainee (PC-V e PC-VI). Unusual occurrence was a teacher to admit the need to have a course to extract the fear of getting trainees (PC-VIII).

It is observed by the teachers that they view this process in a personal manner, explaining, "your way", how to be a teacher, and consider what is more appropriate for this moment, having prerogative about your the workday and mention the lack of time, being the addition of any extra activity can mean more work.

The questions and the perspectives of Trainees about the Teaching Practice in Supervised Training

In the notes of AMs about the internship, have been identified the need and fear of being exposed towards the students of the school to say that the training involves:

> *to coordinate children (...) to put me as a teacher (...) to get children's attention, respect (...) I believe that the difficulties were more in the classroom in order of to be the first time we can see in front of children as a teacher* (AM-I).

This fact is also evidenced by Freire (1994) to admit that in the first days of conducting there is insecurity, shyness and fear of not to be able lead the planned activities. On other side there is the recognize that "[the teacher] *she has this ability of predict what will happen, unlike of us that enter just thinking that everything will be right and that does not always give*" (AM-V).

In this way, it points the school as a place that the reality "presents itself", because "*There is the strongest experiences (...) is the contact with people, (...) is not just things on paper (...) there has the emotions, (...) the events, there we go through the things, indeed*" (AM-IV).

In this way, it points the school as a locus of training, a place where there is the improvisation of acting in emergency, decide on the uncertainty, finally a place that allows review of previous knowledge linked with the exercise of autonomy (Perrenoud, 1997, as cited in Benites, 2007). In this place, Borges (2004) indicates that the teaching practice "will be certainly, a more natural experimental situation, close to real (...)" (p. 150). Although there is it understanding, there is need to put that depending on the conception of training, teaching practice or teaching profession to PCs, this moment can walk to negative experiences due to lack of understanding of this process: "*The difficult internship was relationship with the teacher (...) I was there to learn from her (...) the Internship conception of her was different, because I was always the listener, the (...) helper*" (AM-II).

In this way AM-V pointed out that "*no contact with the university professor with the other teachers (...) for mentor to receive trainee, she has to be prepared, and I felt that missed this preparation on my teacher*"

From this perspective, the training of the teacher was seen as crucial by AMs (AM-V, AM-VI e AM-X) with regard to preparing trainees to receive and they insist (AM-I e AM-VIII) in indicating the participation of teacher in a training course. In the same way AM-II and AM-V showed to they felt the lack of a teacher preparation, AM-IV stressed that it would be essential that the teachers had another understanding of the training process.

For trainees, the school's management team created some dissatisfaction about the orientation process of the future profession (AM-IV), still reporting that it was bad (AM-III). The AM-I told that *"management it is quite impartial (...) the trainee is a teacher's problem"* (AM-I).

This issue it is a problem that remains unresolved on the new Law Internship (Brazil, 2008), or on guidelines of the National Council of Education. There is no guidance for schools and teacher with regard to training of their future professional and co-workers respectively, covering the didactic and pedagogic aspects of learning the profession. The training of basic education in schools as it appears established, reflects more than a tacit agreement of good will, favor, fellowship, among other things, than a professional activity.

From the perspective of teaching as they were taught (Goc-karp & Zakrajsek, 1987), break or not with the conception of education, teaching profession (Tardif & Raymond, 2000), or even get stuck to the images and representations of school and teacher coming of primary socialization, there is the need to assume the role of teacher, to see himself as a teacher and not as a student; the same way that it becomes essential the mediation which the professor (university) makes with school and vice versa. This is a double track road, but that has persisted in following the one way.

CONCLUSION

In the study presented, it was found that the legislation leaves no forwarding features about training and / or teacher preparation to receive trainees. Concerns about the training of future teachers are in charge only of the university, leaving elementary school and the state itself without a formal responsibility. There is the Law Internship, but it only better organizes the issue of structural internships, there are progresses in this process but not in the case of Bachelor, because this context does not change substantially.

The study identified in the analysis of reports from students, the conception that they had to training and teaching, as well as understanding of the difficulties found during this process. It was observed that students, when they come into contact with professional practice feel insecurity and difficulties in relation to the pedagogical procedures. The fear of the new is present on the beginning teaching as well as the insecurity due to of not know the practice and the school reality from the perspective professional.

Therefore the discursive reality of the university, based on the theories and fundamentals, clashes with the pragmatic reality of the school expressed in "act urgently and decide on the uncertainty" (Perrenoud, 2001), leading these students to have to reframe their conceptions and practices.

From the reports of students and teachers, we found two types of forwards with respect to the teacher trainer: the first being that train the student from the model "trial error" (Garcia, 1999a), while the second works from a reflective perspective, with the support of experiential knowledge.

Among the PCs, only three had the understanding that the internship is a learning space for the future teachers, being that from these, two said they had done preparatory course to receive the trainees, indicating that it is something that cannot be ignored. Therefore, the initial teacher training requires a reformulation of the adequacy of the Teaching Practice / Supervised Internship in particular, and the Law Internship regarding to teacher training.

As a perspective, Borges (2008), based on studies by Tardif (2000) and Bourdoncle & Lessard (2003), suggests us the professional training model centered on the epistemology of professional practice on which appreciates the knowledge of experience. In this proposal, the school becomes the center of the future teachers' education, involving not only the mentor but also a university professor and trainees, as well as principals, educational coordinators, supervisor of education, etc.

We conclude that there is need to value the school as a locus of training, taking to school the responsibility for education of future teachers concurrently with the university.

348 - Self-Efficacy Beliefs of Brazilian Student Teachers of Physical Education in Situations of Teaching Practice

Roberto Tadeu Iaochite[1] and Samuel de Souza Neto[2]

Department of Education, Institute of Biosciences, State University of Sao Paulo, Brazil
[1]iaochite@rc.unesp.br, [2]samuelsn@rc.unesp.br

Abstract: Teacher self-efficacy is the judgment about teacher capabilities to achieve, within the teaching domain, determined learning outcomes and students' engagement (Tschannen-Moran & Woolfolk Hoy, 2001), and it is constituted by four sources: mastery experiences, vicarious experiences, social persuasion and physiological and affective states. This study aimed to measure and analyze the strength of self-efficacy for teaching and the sources of this belief. 114 students in final grade (fourth year) of undergraduate courses participated. Data was collected by two Likert-type scales of six points – *Physical Education Teacher Self-Efficacy Scale,* and *Teacher Self-Efficacy Scale Sources*, and a questionnaire of characterization of the participants. Student teachers presented moderate self-efficacy belief (M=6.69) for teaching. Vicarious experiences (M=4.73) and social persuasion (M=4.61) were the highest scores to constitute this belief. The results provide directions for reflection about the teaching practices during undergraduate courses, and practices of physical education teachers in service.

Keywords: Teacher self-efficacy, Teaching practice, Physical Education

INTRODUCTION

Teaching, as pointed out by Gibbs (2003) is a task that requires specific knowledge, skills, and beliefs. It is closely related to the context, to the characteristics of teachers, students, school, family, etc. With greater or lesser intensity and frequency, it is mainly in teaching activities that teachers are driven to rethink their practices and their knowledge about their own ability to deal with the context in which they work, confronting and managing these claims.

When looking at the work of the physical education teacher at the school in recent years, the challenges are neither few, nor even simple. Teaching Physical Education carries some peculiarities and challenges in relation to other subjects in the curriculum, as the physical space, the dynamics of classes and the students' exposure. In the Brazilian school scenario, there are some of them like changes in curriculum content, new government policies, increased rates of absenteeism of students, especially in high school, lack of students´ motivation to participate in classes, limited support of the government bodies, of the administrative board of the school, low status among peers from other areas, etc. (Bracht et al. 2002; Darido, 2004). This seems to be no different in other countries as demonstrated by the studies of Marshall & Hardman (2000) and Martin & Kulinna (2003).

When contextualizing the teaching practice in physical education, it is important to note that his process implies to reflect critically, to discuss, to make choices, and to support the decisions made in the uncertainty of the complexity of the teaching process considering the context and the possibility of developing autonomy. Therefore, it is essential that teachers have clarity of the multiple contributions of Physical Education as school subject. Also, they must see themselves able to turn into reality such contributions, considering a set of factors on various levels: physical, political, administrative, professional, and the difficulties they face in the daily actions at school.

Given the complexity that permeates education, it is essential to search for theoretical frameworks that contribute to the understanding of which variables, how they relate and affect the judgments that teachers make about their abilities and skills to manage such demands. Besides, it appears to be equally important the choices to be made, the decisions to be taken, as well as the consequences of these actions in the school.

In this direction, this study is on the framework of Social Cognitive Theory, specifically the construct of self-efficacy proposed by Albert Bandura (1986, 1997), offering contributions to the pedagogical practice of the physical education teacher at school. Self-efficacy is, according to Bandura (1997), the main mechanism that enables this operation and refers "to beliefs in one´s capabilities to organize and execute courses of action required to produce given attainments" (p.3). The studies that deal with self-efficacy beliefs have been gaining ground in the academia for over three decades, and their insertion has occurred in contexts related to education, health, high-competitiveness sports, among others.

Once recognizing the role of the beliefs in human functioning, especially in the context of teaching, it seems possible to consider that, as important as acquiring the skills, competencies and knowledge needed for teaching, teachers need to believe they will be able to exercise their roles with some success.

About this issue, Bandura (1997) states that self-efficacy beliefs "operate as a key factor in a generative system of human competence" (p.37). He adds that an effective operation requires skills and self-efficacy beliefs to use well the skills one possesses. According to him, "perceived self-efficacy is not a belief about the skills one has, but on the belief of what one can do under different conditions with the skills he possesses." It is in this direction that knowing and understanding the construction of self-efficacy beliefs of teachers can generate knowledge for planning situations that promote high self-efficacy beliefs, especially by higher education institutions in the process of educating future teachers.

Bandura (1997) postulated the existence of four sources that constitute the self-efficacy beliefs, they are: a) enactive mastery experience, b) vicarious experience, c) verbal persuasion and d) physiological and affective states related to the activity performed. In the context of teaching practices, the experiences directly lived by the student teachers in everyday teaching practice constitute the most effective way to create a strong sense of efficacy. One important aspect of this type of source, and that goes beyond the results achieved in fulfilling the task, is to provide information about his ability, not just about the performance achieved.

According to Bandura (1997), performance by itself does not provide enough information to judge the level of one's capabilities. When people experience the success easily, they are unlikely to persist when failure occurs. On the other hand, when someone succeeds in an activity and this result is assessed as positive and derived from one´s own effort to overcome obstacles present in the activity and / or the environment, this often increases the belief in one´s capability to perform this activity or similar ones (Bandura, 1997).

A second way of building this belief is through the experiences learned via observation of social models. Observing other teachers teaching classes, watch movies and videos related to teaching are examples of how this type of source can contribute to construct teacher self-efficacy. Bandura (1997) points out that "[...] competent models transmit knowledge and teach observers effective skills and strategies for managing environmental demands" (p. 88). To Tschannen-Moran, Woolfolk Hoy & Hoy (1998), teachers regarded as models of success are the foundations to show that teaching can be a task able to be handled, and the personal and the context resources may be appropriate.

The verbal persuasion works insofar as it seeks to persuade another, usually verbally. The constant dialogue between supervisors, student teachers and teachers with the goal of providing feedback, guidelines, praises, etc., may facilitate the beliefs of self-assertion so that they create self-incentives for the development of the skill level, of self-efficacy beliefs and this dialogue can provide information about the performance through feedback (Bandura, 1997). It also affirms that the impact that persuasion can cause in the construction of the belief, depends on the credibility, knowledge and experience of the persuasive source on the activity.

The fourth source of information of self-efficacy belief is called physiological and affective states. Level of activation (arousal), fatigue, stress, anxiety, tension, pain, mood states are manifestations that can alter the perception of self-efficacy, because they directly affect the judgment that people make about their own capability to accomplish a given task. When student teachers are teaching, especially those who consider themselves insecure, they may trigger different psychophysiological reactions - excessive sweating, falling blood pressure, heart beat and mood changes etc. The interpretation given to these reactions tend to influence the mobilization of efforts to carry out a given task (Mulholland & Wallace, 2001; Tschannen-Moran, Woolfolk Hoy & Hoy, 1998).

Considering these issues, it is possible to think of initial training courses in order to make them offer these grounds so that future teachers can add new knowledge about the teaching profession from a perspective that considers the teacher as a pro-active subject that, in the interaction with the context, can see himself capable to cause changes in the reality of the classroom, of the school and of the community around it. The necessary subjects for the formation of a physical education teacher in the Brazilian reality are related to educational knowledge and, among these, the Teaching Practice occupies a privileged place. The Brazilian legislation in the area of teacher education determines 800 hours of practice as a curricular component, and supervised internship. The objective is to promote the articulation of different knowledge that had been developed over the course within an interdisciplinary perspective.

Thus, this research is related to situations of teaching practices in physical education and aimed to identify and analyze the strength of self-efficacy for teaching, and the sources of this belief with student teachers from Vale do Paraíba, São Paulo, Brazil.

METHODOLOGY

Participants

114 senior physical education teacher students participated in this study. 54.4% are male and 45.6% female. The age range of the participants was from 19 to 46 years old, with an average of 24.6 years old and standard deviation of 4.92 years. All of them were bound in undergraduate courses in physical education from three private institutions of higher education in the state of São Paulo, in Vale do Paraíba. The average of weekly trainee hours was 16.01 hours with a standard deviation of 9.6 hours. Students completed this schedule for an average of seven months, approximately, with 56.6% of respondents spending time in public institutions and 43.4% in private ones. The majority (94.7%) of them went as trainees in elementary school. As for the context of the training, 79.8% felt themselves supported by the governing body of the school, 81.6% perceived that there was freedom so they could express their ideas with teachers in schools, and 86.8% felt well prepared to undertake supervised practice in schools.

Instruments

The respondents answered the characterization questionnaire of the participant and of his teaching, which aims to obtain information about the participant such as sex, age, whether future teachers took the internship in public or private institutions, and other information.

For assessing teaching self-efficacy, the Teachers' Sense of Efficacy Scale longer version was used, (Tschannen-Moran & Woolfolk Hoy, 2001) translated into Portuguese by Polydoro et al., 2004. The Portuguese version is a Likert scale with an interval of 6 points, 1 (little) to 6 (very much), comprising 24 items distributed in two dimensions - the intentionality of teaching and classroom management. However, in this study, given the results of factor analysis, it was chosen the dimensionality of the original version, i.e., three factors as proposed by Tschannen-Moran & Woolfolk Hoy (2001). This is a Likert scale with an interval from 1 to 9, with the meaning of graduation in a continuum from 1 (nothing) and 9 (a great deal). This scale consists of 24 items distributed in dimensions: Efficacy for Student Engagement (ESE), i.e., the belief in the capability to mediate and promote the mobilization of the student in order to perform the activities ($\alpha = .91$); Effectiveness for Instructional Strategies (EIS), that is, the belief in the capability to develop strategies to promote thinking and learning for students ($\alpha = .90$), and Efficacy for Classroom Management (ECM), .ie., the belief in the capability to manage the development of teaching activities ($\alpha = .86$).

In order to investigate the sources of teacher self-efficacy, it was used the Sources of Self-Efficacy Scale. It is a Likert scale consisting of a set of 16 statements related to items on the four sources of self-efficacy (Iaochite, 2007). The scale was developed based on the recommendations proposed by Bandura (1997, 2006). The original version was submitted to analysis of two expert judges in the theoretical analysis and the construction of psychological assessment instruments. It was assessed the relevance of the items about the clarity, theoretical precision, language, simplicity and suitability, according to the methodological procedures undertaken by such instruments. The final configuration of the instrument was made after the convergence of opinions and the final acceptance of both judges. The instrument considers a continuum from 1 (completely false) to 6 (completely true) points and tries to analyze the degree of agreement of the respondent to the content described in each item. The factor analysis of the main components with varimax rotation showed that only four factors had eigenvalues greater than or equal to 1.0 and responded to 57.37% of total variance. The scale consists of four dimensions ($\alpha = .81$) corresponding to the postulates of Bandura (1997), and Enactive Mastery Experience ($\alpha = .58$), Vicarious Experience ($\alpha = .58$), Verbal Persuasion ($\alpha = .75$) and Physiological and Affective States ($\alpha = .78$) Data from the first exploratory analysis of the instrument are contained in the study of Iaochite & Azzi (in press).

Data Collection and Analysis

After choosing the set of instruments, Physical Education college professors were contacted. Their selection was done by convenience, through emails and meetings. Professors of three private institutions of higher education in Physical Education in Vale do Paraíba, State of São Paulo, were contacted. During the initial contact with these professors they were informed the study objectives and were asked to grant permission to collect information from the students. Data were collectively collected, in only one meeting in the classroom during the class period and after the permission of the professor. Initially, the study purpose was explained and the invitation for voluntary participation in the study was made. The data collection was made by the author of the study and the instruments were distributed after the participants signed the Term of Consent.

The study was approved by the Ethics in Research Committee (UNITAU # 312/08). Data were analyzed with the help of SPSS (Statistical Package of Social Sciences).

RESULTS

Table 1 shows the results. Participants acknowledged a moderate level of teaching self-efficacy, with an average of 6.78 points for the Efficacy for Instructional Strategies subscale (EIS), then the average of 6.73 points for the Efficacy Student Engagement subscale (ESE), and finally, the subscale Efficacy for Classroom Management (ECM) obtained 6.58 points in a nine-point scale.

According to the statistical analysis of the level of self-efficacy of participants for each item of the scale, the results show that for the EIS factor, the scale items with the highest and the lowest values were, respectively, "How well can you provide appropriate challenges for very capable students? "(M = 7.26, SD = 1.57) and "How much can you adjust your lessons to the proper level for individual students?" (M = 6.49, SD = 1.78).

To the dimension ECM, the item "How much can you get children to follow classroom rules?" was the most scored one (M = 6.91, SD = 1.71), whereas the item "How much can you do to control disruptive behavior of in the classroom?" received the lowest score (M = 6.15, SD = 1.71). The items "How much can you do to get students to believe they can do well in schoolwork?" (M = 7.12, SD = 1.56) and "How much can you do to get through to the most difficult students?" (M = 5.70, SD = 1.74) received respectively, higher and lower scores on ESE factor.

Table 1

Mean scores, standard deviations on student teachers'ratings on the Teachers' Sense of Self-Efficacy Scale *(N=114)*

Item	M	SD
Efficacy for instructional strategies	6.78	0.04
24. How well can you provide appropriate challenges for very capable students?	7.26	1.57
20. To what extent can you provide an alternative explanation or example when students are confused?	7.06	1.66
11. To what extent can you craft good questions for your students?	6.88	1.75
18. How much can you use a variety of assessment strategies?	6.75	1.75
23. How well can you implement alternative strategies in your classroom?	6.75	1.74
7. How well can you respond to difficult questions from your students ?	6.60	1.38
10. How much can you gauge student comprehension of what you have taught?	6.60	1.81
17. How much can you do to adjust your lessons to the proper level for individual students?	6.49	1.78
Efficacy for classroom management	6.58	0.04
13. How much can you do to get children to follow classroom rules?	6.91	1.71
19. How well can you keep a few problem students form ruining an entire lesson?	6.85	1.60
21. How well can you respond to defiant students?	6.79	1.80
5. To what extent can you make your expectations clear about student behavior?	6.60	1.59
8. How well can you establish routines to keep activities running smoothly?	6.60	1.62
15. How much can you do to calm a student who is disruptive or noisy?	6.55	1.56
16. How well can you establish a classroom management system with each group of students?	6.39	1.80
3. How much can you do to control disruptive behavior in the classroom?	6.15	1.71
Efficacy for students engagement	6.73	0.09
6. How much can you do to get students to believe they can do well in schoolwork?	7.12	1.56

Table 1

Mean scores, standard deviations on student teachers'ratings on the Teachers' Sense of Self-Efficacy Scale *(N=114)*

		(Cont.)
12. How much can you do to foster student creativity?	7.02	1.68
9. How much can you do to help your students value learning?	6.93	1.62
4. How much can you do to motivate students who show low interest in schoolwork?	6.91	1.84
14. How much can you do to improve the understanding of a student who is failing?	6.81	1.72
2. How much can you do to help your students think critically?	6.55	1.81
22. How much can you assist families in helping their children do well in school?	6.48	1.98
1. How much can you do to get through to the most difficult students?	5.70	1.74

Moreover, the data of the scale on teacher self-efficacy sources were analyzed. As shown in Table 2, data demonstrated that the source which the participants attributed the highest score was Vicarious Experience (mean = 4.73, SD = 0.54). Then it was followed by Verbal Persuasion source (M = 4.61, SD = 0.66). The sources named Physiological and Affective States (M = 4.25, SD = 0.38) and Enactive Mastery Experience (M = 4.07, SD = 0.67) were those which received lower scores.

Finally, Table 3 presents an exploration of potential relationships between: perceptions of self-efficacy for teaching of the student teachers, sources of self-efficacy, and the variable related to the context where the trainee was performed. This variable was composed by the items "type of institution where the internship happened - public / private)", "conditions of the infrastructure of the space of classes", "support of the administrative board", "freedom to express ideas with teacher-employee", "feeling prepared to perform the job". The correlations were mostly highly significant (p ≤ .001) among nearly all variables, especially between the factors of the teacher self-efficacy scale (r = .84 = .89). Moderate correlations were found among the sources of teacher self-efficacy (r = .33 = .57), between the factors of the teacher self-efficacy scale and sources (r = .22 = .29). Regarding the association among the teacher self-efficacy, the context, and the sources of self-efficacy, both Verbal Persuasion and Mastery Experience sources (r = .29 and r =.21), as well as the ESE factor (r = .26) were weakly associated with the context.

Table 2

Mean scores, standard deviations on student teachers'ratings on the Sources of Teacher Self-Efficacy Scale *(N=114)*

Item	*M*	*SD*
Enactive Mastery Experience	4,07	0,67
13. Facing challenging situations and they spend more effort as a teacher is contributing to what I think about my ability to teach.	4,96	1,06
1.What I think about my ability to teach concerns and experiences that were important to me.	4,49	1,28
5. The mastery experiences of my teaching practice affect what I think about my ability to teach.	3,74	1,63
9. When I make mistakes, it affects what I think about my ability to teach.	3,10	1,38
Vicarious Experience	4,73	0,54
14. Note explaining competent teachers on teaching practice - what they do, how they do so – Influence what I think about my ability to teach.	4,97	1,15
2. Observe skilled teachers teaching contributes to what I think about my ability to teach.	4,91	1,21
10. When I mentally visualize successful experiences in my teaching practice, this contributes to what I think about my ability to teach.	4,61	1,21
6. Watching movies or videos of competent teachers contributes to what I think about my ability to teach.	4,42	1,41
Verbal Persuasion	4,61	0,66
15. Hear comments from people who admire recognizing my progress as a teacher affects what I think about my ability to teach.	5,31	,085
3. Hear comments about my work as a teacher made by teachers that I admire, influences what I think about my ability to teach.	5,08	1,11
11. Receiving feedback from my students evaluate my teaching practice influences what I think about my ability to teach.	4,60	1,22
7. Comments that depreciate my teaching practice affect what I think about my ability to teach.	3,47	1,62
Physiological and Affective States	4,25	0,38
12. The perception of positive feelings during my teaching practice helps when I think about my ability to teach.	5,18	0,85
4. When I realize that I'm looking forward, it affects what I think about my ability to teach.	4,04	1,47
16. Changes in my mood during my practice as a teacher affect what I think about my ability to teach.	3,95	1,59
8. Symptoms such as fatigue, pain, irritation, are indicative that affect what I think about my ability to teach.	3,85	1,58

DISCUSSION

The study aimed to identify and analyze the strength of self-efficacy for teaching and the sources of this belief with student teachers of physical education. This started from the assumption that identifying self-efficacy for teaching and its sources in teacher education students is the first step to suggest adjustments and changes in the perception of confidence to teach.

The results presented a moderate level of self-efficacy for teaching with the Brazilian student teachers participating in this study. These results agree with literature, to the extent that other studies show student teachers with self-efficacy beliefs for teaching above average. Yilmaz & Cavas (2008) when investigated the effect of the practice of teaching science on self-efficacy for teaching, and for classroom management of Turkish pre-service elementary teachers, they found that nearly all (n = 185) had from moderate to high self-efficacy for teaching. Similar results were found in the study by Poulou (2007) with 198 fourth-year students from primary education departments in Greece, these students obtained higher scores for the ESE and similar scores for EIS and ECM. Bakar et al. (2008) in a study with science student teachers in Malaysia reported that the highest level of self-efficacy for teaching was linked to the ESE and that all dimensions of teacher self-efficacy were positively correlated with the preparation course.

Harlin et al. (2007),when they were studying the development of teaching self-efficacy belief over time of American agricultural science student teachers, found high self-efficacy beliefs at the beginning of the semester (with no teaching experience). Throughout the teaching experience, the scores decreased, and increased again at the end of teaching practice. Studies in the context of physical education in different institutions of higher education, have found similar results as this investigation. In general, the scores range from "some influence" and "quite a bit" (5-7 points). Silva, Iaochite and Azzi (2010) conducted a study with student teachers from four private institutions resulting in a mean score slightly higher for the dimensions of instructional strategies and student engagement in relation to classroom management.

Specifically in the area of teaching in physical education, or studies that include in-service teachers of this subject had scores for moderate and high perceived efficacy related to teaching (Onofre, Carreiro da Costa & Marcellus, 2001; Iaochite, 2007, Martin & Kulinna, 2005, Nix 1998).

Similarly or more important than identifying the strength of teaching self-efficacy in teachers, it is to know how this belief is built. Reports from teachers indicate that the perceived capability to teach is built from information gathered from various sources, such as the experiences of success and failure related to the role of being a teacher, and perceived feelings from these experiments. Also, from the feedback received from students and directors, the possibility of observing other colleagues teaching classes and by combining these and other information related to the teaching task and to the context where the teaching occurs. Bandura (1997) argues that self-efficacy beliefs "are the product of cognitive processing of diverse sources of efficacy information conveyed enactively, vicariously, socially, and physiologically. Once formed, efficacy beliefs contribute to the quality of human functioning in diverse ways"(p.115).

The results showed that among the sources postulated by Bandura (1997), the situations related to vicarious experience and verbal persuasion are the ones which had the highest averages, respectively, contradicting the results obtained by Poulou (2007). One hypothesis that is raised on these results is that the student teachers had few opportunities to practice teaching directly, since most schools did not allow student teachers to conduct the classes. This could even justify the low score obtained by the set of situations related to enactive

mastery experience. Thus, among the opportunities that the internship program can offer, observation and dialogue with the teachers at school were the most commonly performed. It is a fact that observing good teachers, especially the ones with similar characteristics as the observer, contributes to increase teaching self-efficacy (Bandura, 1997; Tschannen-Moran & McMaster, 2009). However, the observation of actions which are not appropriate for teaching, with the proper reflection of how these could be associated with different pedagogical knowledge, can serve as sources for the determination of how much one is capable to act in another direction other than that of the observed model. According to Schunk (1987, in Usher & Pajares, 2009) "they (students) are most likely to alter their beliefs following the model's success or failure to the degree that they feel similar to the model in the area in question" (p .89). She adds that, self-comparison of current performances with past ones is another type of vicarious experience that can alter one´s self-efficacy.

In this investigation, among the items displayed in the scale about the sources of teacher self-efficacy, "Listening to comments from people who I admire recognizing my progress as a teacher affects what I think about my ability to teach" was the highest score obtained (M = 5.31). Verbal persuasion was the source with the highest score and was positively associated with teaching self-efficacy, like the studies made by Lonney (2003) and Gür (2008) with the aim of examining the predicting variables of self-efficacy of science teachers in elementary schools in Turkey, they found that for beginning teachers, verbal persuasion was also a predictor of teaching self-efficacy beliefs. Since the school in its social nature, is one of the most significant spaces for the construction and development of knowledge, beliefs, abilities and personal skills, communication and social interaction can be boosting this construction.

Although one of the items with higher scores are linked to physiological and affective states, namely, "The perception of positive feelings during my teaching practice helps when I think my about my ability to teach" (M = 5.31), the scores from this source and the enactive mastery experience had the lowest averages. These results partially agree with data from other investigations (Mullholand & Wallace, 2001; Poulou, 2007). As for the source of enactive mastery experience, the fact that the student teachers, mostly, could not directly experience teaching at the school may have contributed to the low score of this source in this investigation.

Finally, the correlations found between the variables, especially between teacher self-efficacy and the sources of information, albeit weakly associated, encourage the search for future investigations that might better explain these relationships. Moreover, through these associations, it is possible to confirm the theoretical postulations that the constitution of the belief occur by different pathways, since it depends on the assessment that the teacher makes on both the task of teaching and on the skills one has to perform it under the existing conditions (Tschannen-Moran, Woolfolk Hoy, Hoy, 1998). This means to say that the way each source relates (impacts) on self-efficacy depends on the cognitive processing of this information, that is, of what is remembered and the value (meaning) that they pose to the teacher. Bandura (1997) explains that the sources that carry some amount of efficacy vary as to the degree of information, interaction and complexity of the self-efficacy judgment. He said the relationship may be linear (the higher the contribution of a factor, the higher the self-efficacy) and curvilinear (the moderate level is more adequate than low or high levels). For example, given the contribution of direct experiences as a source of information of capability, it is likely that the more meaningful and positive experiences the teacher has, the higher his self-efficacy is. The same does not seem to be true when it comes to the physiological and affective states, because in lower or higher levels, the physiological activation will depend on how the teacher judges such reactions, which may cause anxiety states or even apathy.

CONCLUSION

This study aimed to measure and analyze self-efficacy beliefs for teaching and the sources of these beliefs. The knowledge, the possibilities and manner of acting that student teachers adopt during their education are mediated by what they think and believe, and in the axis of mediation, there are the self-beliefs of these student teachers, especially self-efficacy (Gibbs, 2003). To this author, the teacher training programs must provide inputs for teachers to exercise self-control over their thoughts, emotions and actions during the teaching process, thus giving special attention to the development and the exercise of self-efficacy in their teaching activities.

However, it is important to consider that direct experience as an information source of self-efficacy should be seen not as something done, but it must be understood as a behavior that is dynamic, multidimensional, constructed, organized and controlled by the cognitive processing of a series of information that are within in this action and through the sub-cognitive and self-regulatory skills, which tend to strengthen as this action is successful over time. Teacher education courses should encourage in their disciplines the practice of teaching in situations that increase the complexity, to the extent that student teachers master the task and express confidence to continue to learn to be a teacher.

According to Bandura (1997) to building high self-efficacy scores, it is important the acquisition of cognitive, behavioral and self-regulatory tools in order to create and perform the necessary actions to manage the changes that occur. He reaffirms the complexity of this process, stating that "[...] having knowledge and skills does not produce high attainments if people lack the self-assurance to use them well"(p.80). As previously mentioned, the moments of academic internship can become - depending on how the teacher in college select, organize and manage the multiple factors involved in the teaching-learning process - excellent opportunities to go beyond these conditions, to build high self-efficacy beliefs in these future teachers.

364 - World Bank, IMF and WTO and the Interference in the Brazilian Educational Policies at the end of the Twentieth Century and in the First Decade of The Twentieth Century

Fabiana Andrea Barbosa Vaz

PUCPR – Brazil
fabiabvaz@uol.com.br

Abstract: This article discusses the role of the World Bank, IMF and WTO in the Brazilian educational policies in the late twentieth and early twenty-first century. Inheritances of post-World War II, these international bodies were established in order to establish interventions and treaties in various fields, among them the educational ones. Until the late 1970s, several of their programs were focused on industrialization policies, using the argument that poverty in the peripheral countries would dissipate the effect of economic growth. However, as of the nineties to the twentieth century, these interferences have affected consubstantially the educational policies of various countries, including Brazil, where an area is noteworthy in different levels of education: evaluation of the effectiveness of investments financed by such bodies in this country. Another point which this article addresses is the merchant issue which settled in the educational field in Brazil, because of the design of the documents placed in these international bodies, in which education becomes a service. This situation becomes clear when analyzing the texts of policies for the Brazilian education at different levels, as well as some reports from these entities, including "Knowledge and Innovation for Competitiveness", published in 2008, which brings an opinion obtained by data from the PISA assessments as to justify the close relationship between economic development and "production" of Brazil's human capital through education.

Keywords: public policies, international organizations, commoditization of education.

This article discusses the role of the World Bank, IMF and WTO in the Brazilian educational policies in the late twentieth and early twenty-first century. Another point that is worked is merchant issue which settled in the educational field in Brazil, because of the design documents placed by these international bodies, in which education becomes a service. In the early twentieth century and especially after the Second World War, around the world, the vision of progress was closely tied to the idea of expanding markets by creating the jobs and the accumulation of capital. The development of poorer countries occurs mainly with technical and financial support of countries that hold more capital. By this historical point, it was believed that the development of peripheral countries depended far more on developing a rational, global and comprehensive model of development than the actions that the countries could take individually.

So, to give "body" to this development ideals, the international organizations were created with the function to assist technically and financially the peripheral countries, including the IMF (International Monetary Fund) and WB[93] (World Bank), which was created in the conference of Bretton Woods in 1944 and which currently has 176 borrowing countries, including Brazil, five countries define the political strategies of action of the bank - Japan, Germany, France, UK and USA, and the last one holds the presidency of the Bank, besides having veto power for the policies and proposed actions.

In the 40's, the resources of the IMF and WB gave priority to the reconstruction of the countries devastated by the war, later they turned their interests to third World development. According to Haddad (2008:7) "Such multilateral financial institutions (IFIs) began to operate in a coordinated manner in the globalized international economy in the deepening and implementation of policies that favor the reproduction of global capital."

---

[93] The World Bank today is composed of a set of organisms, among which the main organism is the IBRD (International Bank for Reconstruction and Development), which includes five other agencies: the IDA (International Development Association), IFC (International Finance Cooperation), ICSID (International Centre for Settlement of Investment Disputes), MIGA (Multilateral Investment Guarantee Agency) and GEF (Global Environment Fund).

Thus, from the mid 50's to early '70s of the twentieth century, around 70% of World Bank loans were intended for industrialization policies in the third World, in order to include the countries of this bloc in the international trade system.

However even with such a policy of financial incentives under the aegis of economic progress in the following decades, something drew the attention of those bodies: the matter of the increasing birth rate and growing poverty and widening gap between social classes in countries served by the programs in place. (Haddad, 2008)

In 1968, Robert McNamara starts in the management of the World Bank, the same period in which the previously dominant view that poverty would be extinct as a consequence of economic growth had already weakened. At that historic moment, according to Tommasi (2007):

> The World Bank began imposing a series of conditions for the granting of new loans. Through these conditions, the World Bank (as the IMF) started to intervene directly in the formulation of domestic policy and to influence even countries' laws. Thus, as of the 80s, the character of the relationship between the World Bank and the developing borrower countries profoundly changed. Overcoming the traditional influence that it already used to have on the sector policies of developing countries, the World Bank came to exercise extensive control over the set of domestic policies being a key part in the restructuring process in these countries over the past fifteen years. (p. 21)

In the late eighties of the twentieth century, the world was immersed in the Neoliberal ideology, which was stamped on the world public policy and introduced itself as the only way of action for the developing countries so that they could be inserted in the context of modernity. However, it is known that it did not. Instead, national governments, including Brazil, have found themselves constrained to meet the political and economic demands that contribute even higher dependence and vulnerability to decisions made internationally.

The neoliberal ideology finds support in the design of the minimal state, which implies an inversion / resizing of the powers of the state, directing their actions to minimum services such as policing, for example. The regulation of services, including education, must be made by the market, so words such as competition, efficiency, total quality and rational use of resources gain strength in that context.

> The current neoconservative policies recommend to gradually reduce public investment in education, and eventually to their complete elimination. It considers that the state monopolized functions which belonged to private companies and advises reversion of this relationship, especially in poor countries. (World Bank, as cited inPuiggrós, 1997, p.224)

At that moment in history, education, knowledge and science gained a key role in the global scenario, marked by extremely technical and the new production and development paradigm once they are seen as a driving force for productive transformation and economic development of societies. Therefore, the connection between education and knowledge-development-economic performance is evident, and the education is pointed, in the neo-liberal perspective, as a problem closely linked to economic bases. Here there is no room for unqualified workers, who is unable to abstract new technologies and who do not have autonomy in carrying out their activities (Oliveira, 2009).

In order to have a coalition of forces between the national economic and educational objectives, according to Haddad (2007),

> The mechanisms of influence from the WB reached the guidelines of educational policy always in complement to the educational macroeconomic guidelines established by Brazil in its agreements with the IMF. Thus, for example, while the macroeconomic guidelines determined the spending cuts and structural adjustment, the guidelines of the WB in education, to be coherent, focused resources in elementary school, they were more concerned with efficiency than with the system increased spending, operating under the logic of cost-effectiveness. They bet on the idea of expanding the service with the same amount of resources. (p.11)

This communion of actions demonstrates the magnitude of interference in the decisions of these bodies on national public policies, once education is now seen as a strong component related to the economy; the project must be united so that conditions can be generally and totally met, at least in quantitative terms.

Oxfam apud Silva, Azzi and Bock (2008:21) notes that "despite the Bank and the Fund play different roles, one cannot have one without the other. (...) Studies have stipulated that the Bank-financed projects bring an average of 114 conditions, if one computes the IMF ones which are automatically linked to them."

A clear example of this relationship education / economy is found in the document "Knowledge and Innovation for Competitiveness", published by the World Bank in 2008 where, in 334 pages that compose it, Brazil is mapped and the obstacles faced by it to become competitive globally are considered, having education as one of the bases of the project to leverage the country economically in the international arena.

In order to justify their "concern" about the development of Brazil, the report points out the rating of Brazil in Global Competitiveness Index (GCI) in 2006, pointing out some key items for the consolidation of the ideals of high worldwide competitiveness of Brazil. They are: Institutions, (79) Infrastructure (70), Macroeconomics (91), Health and Elementary Education (52), stimulation of efficiency (51), Sup Education Training (50), Market Efficiency (55), Technological capacity (51), factors of innovation (36), business sophistication (33) and innovation (39). With rates ranging from zero to one hundred, the country at that point is targeted with index 57 in the global level, and throughout the text it points the intimate relationship between low levels for education and those related to innovation[94], presenting a relation of cause and effect. (World Bank, 2008)

According to that document, such low rates of innovation in development are tied to the issues of education inefficiency in Brazil since

> The ability of a nation to create new knowledge and technology is closely related to technical and advanced capability and a higher education system particularly strong in science, engineering and technology application. Brazil has emphasized on the humanities and social sciences at the expense of the physical sciences and engineering. Despite slow but steady growth in the latter disciplines, higher education in Brazil still has very limited capacity to train high-level innovators who can work on the frontier of global knowledge creation. (World Bank, 2008, p.33)

Thus education and the economy eventually are deemed to be linked. The Bank and other agencies end up using the economic analysis as a methodology for an effective and efficient diagnosis and for establishing priorities in both respects.

INTERNATIONAL ORGANIZATIONS AND THE BRAZILIAN EDUCATION: EDUCATION AS A SERVICE

Brazil[95], in the 90's, attended the World Conference on Education for All, held in Jontiem, Thailand, in 1990, it was funded by UNESCO (United Nations Educational, Scientific and Cultural Organization), UNICEF (United Nations Children's Fund), UNDP (United Nations Development Program) and World Bank, with the participation of several governments, international agencies, counting in the end with the signature of 155 governments that are committed to ensuring the effective implementation of the goals outlined here for the following years, as follows (Shiroma, Moraes & Evangelista, 2007):
   • Expansion of assistance and activities that serve to support the early childhood development;
   • Universal access to basic education until 2000; improvement of learning outcomes, reduction of illiteracy rates until 2000 and reduction of inequality of these rates between men and women
   • Expansion of basic education services and training in other essential skills for young people and adults (i.e., programs that would bring impacts in their conduction, in the area of health, employment rates and productivity of the country);
   • Increase, by individuals and families of the knowledge, values, and skills required for better living and for rational sustainable development through channels of education – included in the modern media, besides other forms of traditional and modern communication, and social action - evaluating the effectiveness of these interventions by the modification of conduction.

In addition to the pacts signed in Jontiem, the documents prepared by ECLAC (Economic Commission for Latin America and the Caribbean) during the decade in question also forms a profile of the agreed guidelines

---

[2] The report proposes a typology consisting of three aspects of innovation - (a) creation and commercialization of new knowledge and technology; (b) acquisition of knowledge and technology from abroad for local use; and (c) dissemination and effective application of knowledge and technology (created internally or abroad) that are already available in the country, although not widely used. (World Bank, 2008:32).

[95] During the meeting, Brazil was appointed as a member of E9, listing the nine countries with the highest illiteracy rate in the world: Bangladesh, Brazil, China, Egypt, India, Indonesia, Mexico, Nigeria and Pakistan.

and policies that would guide the actions of Brazil in the late twentieth century. "The strategy of ECLAC was articulated around common objectives (citizenship and competitiveness), the principles underlying policies (equity and efficiency) and guidelines for institutional reform (decentralization and national integration)." (Shiroma, Moraes, & Evangelista, 2007, p. 53)

With the same significance of the agreements Jontiem and ECLAC, one can point the International Commission on Education for the XXI century, which developed in the period 1993 to 1996, the report Jacques Delors, which indicates new urgency to the education of the new millennium and that interfered with his ideals posted there in educational policy to be implemented in Brazil. Among the pressing matters pointed out - the fundamental role of distance education and the need for international cooperation and, regarding the resources for education, the possibility of "mixed funding systems, combining public and private funds in variable proportions according to the levels of education (...)" (UNESCO, 2003:182)

In agreement with the ideals put into Jontiem and in the Delors report, the IBRD (International Bank for Reconstruction and Development) lists a series of elements that compounded the educational reform that took place in several countries of Latin America in the 90's in the twentieth century, among them Brazil (Torres, 1996):

a) *Priority on basic education* - and why basic education? According to World Bank "Education, especially primary and secondary (basic education), helps reduce poverty by increasing labor productivity of the poor, reducing fertility, improving health, and it endows people with attitudes they need to participate fully in the economy and society."(Shiroma, 2007:63)

b) *Improvement in quality (and efficiency) of education as a focus of educational reform*. The quality lies in the results obtained via academic performance. Some input would be crucial for effective learning: In order of priority: libraries, instructional time, homework, textbooks, teacher's knowledge and experience, laboratories, teacher pay, class size. Taking into account the costs and benefits of these investments, the World Bank recommends investing primarily in increased instructional time, the supply of textbooks (seen as an expression of operational curriculum) It is recommended that the production and distribution of these is allocated to the private sector and it directs that providers empower teachers and provide them with guidelines for the use of such material. It also highlights the need for investment in improving teachers' knowledge (favoring in-service training at the expense of training and stimulating modalities at distance).

c) *Priority on financial and administrative aspects of educational reform.*

d) *Decentralization and autonomous school institutions which are accountable for their results*. Governments should maintain only four functions centralized: (1) standards setting, (2) facilitation of the inputs that influence school performance, (3) adoption of flexible strategies for the acquisition and use of such inputs, and (4) monitoring of the academic performance.

e) *Call for greater involvement of parents and community in school affairs.*

f) *Encouragement for the private sector and nongovernmental organizations as active agents in the field of education* (both in decisions and in implementation).

g) *The mobilization and effective allocation of additional resources to education* as the main themes of dialogue and negotiation with governments.

h) *A sector focus*.

i) *Establishment of policies and strategies based on economic analysis.*

These recommendations point to another point strongly emphasized by the World Bank which is the market opening for private enterprise, in other words, the state's role in relation to education is gradually left in large national or international hands, and this must focus its efforts on primary education, justifying its position by stating that other levels of education "are used to meet the needs of the elite." (World Bank, 2003)

The country then has reinforced its position of agreement with the external conditions with the publication of the Ten-year Education Plan for All in 1993 under President Itamar Franco, who took over after the impeachment of Fernando Collor de Mello, a document which "traced the local targets from the agreement signed in Jontiem and indicated to multilateral bodies that the education project they prescribed would be deployed here." (Shiroma, Moraes, & Evangelista, 2007, p.52)

By observing also the Law of Directives and Bases of Education (LDB), Law 9394/96, a view of acceptance of the dictates posted above can be conceived, especially in regard to decentralization. According to Cury (1996), there is a change in the conception of the law; it presents a more flexible planning and centralization of the assessment. With the new law, the control ceases to be exerted from the base - via minimum curriculum, establishment of specific working hours, etc. - Going to be done in the output, via assessment.

This can be seen in Article 9 of the referred legislation, when it points out that the Union is responsible for:

IV - establish, in collaboration with States, the Federal District and Municipalities, skills and guidelines for early childhood education, elementary school and high school, which will guide the curriculum and its minimum contents, to ensure a common basic education;

VI - to ensure a national process to evaluate the academic performance in primary, secondary and higher education, in collaboration with education systems aiming the setting of priorities and improving the quality of teaching. (Brazil, 1998)

The elaboration, by the federal government, of the National Curriculum dates back from the same period, which aimed to establish a baseline for the national curriculum education. Another important point herein is the relaxation of the proposal, allowing autonomy to schools in order that they could themselves, with the involvement of the school community, develop their pedagogical goals and meet their local needs.

Another international interference, which changed the look about education in Brazil in recent years has been the inclusion of education on the agenda of the occupations of the WTO - World Trade Organization, which was established in 1995 and that currently has the participation of 151 countries, confirming the view we have about the world education: one more service offered along with others that predict consume, customers, clients, the law of supply and demand, etc.

This attitude ends up hurting the famous motto "Education, right of all and duty of the State and the Family" which can be found in the Constitution of Brazil, 1988, article 205, the same right that is guaranteed by the Law of Directives and Bases of National Education (9394/96):

Article 2 The education, duty of the family and state, inspired by the principles of freedom and the ideals of human solidarity, aims the full development of the student, his preparation for the exercise of citizenship and his qualification for the job.

Reinforcing this position, Oliveira (2009:238) notes that:

(...) education should be understood, therefore, as a basic universal right and a public social property. It is thus a condition for social emancipation and should be designed on a democratic and quality perspective in the context of a wider social inclusion project.

Thus, by "losing its strength as a right guaranteed by law", Education interferes with other rights of the citizen, since only conscious, trained reflective about his actions, the man can fight for the right to decent housing, or a healthy diet, a work that does not explore him, among others.

Our attention is also drawn, in this market logics, to the inclusion of education on the agenda of work of the GATS[96], an agreement that discusses on the Education (General Agreement on Trade in Services), was signed in 1994, but negotiations started only in 2002, and "represents the first attempt to draw up international rules for the liberalization of trade in services." (Silva, Gonzales, & Brugier, 2008, p.91)

Brazil, along with 6 other countries, did not opt for liberalization of education in agreement with GATS proposals, seeking to preserve their national identity, but "that does not mean that there are no important processes of privatization and commercialization of education underway in the country." (Silva, Gonzales, & Brugier, 2008, p.124)

In the logic of trade in services, they are seen as commodities and the liberalization for foreign capital is seen as a way to maximize profits by reducing the student to a client. This is evident when one realizes the high spending in recent years in marketing done by education companies, to establish their brand and image in order to attract the market, their potential customers. However, in this perspective of trade, education ceases to be a key category, making room for others as cost-benefit, efficiency, competitiveness, etc. In Torres words (2007)

Education is summed up into a set of inputs which intervene in the *black box* of the classroom - the teacher being one more input - and the learning is seen as the predictable result of the presence (and eventual combination) of these inputs (p. 140).

---

[96] GATS divides the services into twelve sectors: Commerce, Communication, Construction and Engineering, Distribution, Education, Environment, Financial Services, Health, Tourism and Trips; Leisure, Culture and Sports, Transportation; "Other". (Silva, Gonzales, & Brugier, 2008, p.91)

The opening of the educational market to private groups happened in Brazil consubstantially in the late twentieth century and continues in the beginning of this century in Latin America, especially in the field of higher education in Brazil. Recent mappings show that the policy was strongly enforced, thus contributing to a considerable growth in offering higher education in Brazil.

According to data from two censuses carried out by NIS (National Institute of Studies and Educational Research Anísio Teixeira) in 1995 and 2009, respectively, while in the late twentieth century Brazil had **894** institutions of higher education at different levels (public universities - 72; private - 63 / 10 public integrated colleges, 101 private institutions; Public Isolated institutes – 128; 520 private ones, for a total of 894 higher education institutions in the country - **with 210 public and 684 private institutions**) in 2009, Brazil already had **2,314** institutions of higher education and of these **245 public and 2,069 private** institutions. The census also shows that there were 186 universities, 127 university centers, 1,966 colleges and 35 public federal institutions of professional and technological education.

So in this market logic, consumers' opinions about the service offered render great significance, thus justifying the need to have teachers and students evaluated for their efficiency and for their productivity, receiving prizes and awards for their performance in pursuit of total quality. (Haddad, 2008)

So, the various initiatives of evaluation proposed in the national public policies since the beginning of the XXI century are necessary. One such initiative was launched by the then president, Luis Inácio Lula da Silva in 2007, the EDP[97] - Education Development Plan, incorporating nearly fifty programs to improve the rates of national education, including the assessment of student performance, called Brazil Exam.

> Aiming to identify the problems affecting the quality of Brazilian education, the PDE has promoted a change in the national assessment of basic education with the creation of "Brazil Exam." Based on this, MEC sought to cross the results of school performance (Brazil Exam) and school efficiency results (flow determined by school census) into a single indicator of quality: the Index of Basic Education Development (IBED). (Ferreira, 2009, p.262)

Other mechanisms that stand out in this context are the evaluative Saeb System (Basic Education Assessment System) established by Decree No. 931 of March, 21st 2005, which is composed of two processes: the National Assessment of Basic Education (NABE) and National Assessment of Educational Achievement (NAEA). HENAS[98] (Higher Education National Assessment System), which was created by Law No. 10,861, on April 14th 2004 and evaluates the institutions, courses and student performance, this being done through the NESP (National Examination of Students Performance). There is also the HSNE (High School National Exam), taken when leaving high school, which was established in 1998 and aims to obtain an overview of the graduating students' training from high school nationwide, as well as, from 2010 on, replacing the mandatory entrance examination for admission to higher education in Brazil, where many universities have already replaced their regular screening tests by grades obtained by the students in HSNE.

Here we can make a questioning about the real purpose of many evaluation processes. First, are they actually being used so that data are listed and faulty data are corrected, seeking a quality education or are they just following protocols for the demands of international organizations? What would be the evaluation design that guides such assessments? What are the real motivations for these assessments to occur?

According to Hochman (2007):

> (...) in the 60's, the assessment was marked by the mechanistic fallacy of the top-down planning, i.e., we expected an automatic use of their results, in an exclusively instrumental perspective, as a beacon of the decision making and as a tool for rational problem-solving. (...)A second type (...) is the one called "conceptual", usually associated with local managers of public programs, which, even at times when they are prevented from making instrumental use of the evaluation report, can from it, change

---

[97] The EDP includes a set of programs to give organization to the national education system, mobilizing the whole society to improve the quality of education; it is an executive plan, consisting of programs divided into four guiding principles: basic education, higher education, professional education and literacy. (Ferreira, 2009:261)

[98] Sinaes evaluates all aspects that revolve around these three areas: teaching, research, extension, social responsibility, student performance, management of the institution, body of professors, facilities and various other aspects. The information obtained from the Sinaes are used by IES for the guidance of its institutional effectiveness and academic and social effectiveness; by the government to guide public policies and for the students, parents, academic institutions and the general public, to guide their decisions regarding the reality of courses and institutions. Quote taken from http://www.inep.gov.br/superior/sinaes/, site consulted on March, 12th 2011 at 5:00 pm.

their program design and its operation and impact, acquiring new ideas and insights. It is about highlighting an "educational" function of the evaluation. A third type of use would be what we call "persuasive." Aware of the inefficiency of the program and the most feasible changes, managers and operators can use the assessment to legitimize their position and rally support. (p. 331)

It is known that constant evaluation in search of total quality in education is one of the measures proposed by international bodies like the World Bank. In the words of Horn, Wolff & Vélez as cited in Faria (2007) assessments should be used according to the protocol of the World Bank's suggestions:

(...) To obtain public support for improving the quality of education, to improve the design of instruction and teacher training, use of "spillover effects" of an evaluation (beckwash effects), for diagnosis and treatment of learning problems, for the offer of "a reward for good deeds", for the assessing of the progress made by different regions, municipalities, schools or school districts; for research and educational development (p. 339).

This policy of evaluation presented mainly in the early years too unsatisfactory results to be presented in international reports. Thus, according to Puiggrós (1997)

(...) the World Bank encouraged all countries to establish the Common Basic Contents of compulsory education in public and private places (...) with it the educational model neoconservative is completed: It sends the state away from education and puts the market in place, easing all the economic controls and establishing, soon after, strict controls on ideology. The freedom of the market is combined, then, with ideological conservatism. (p. 234)

In the aforementioned document "Knowledge and Innovation for Competitiveness", published in 2008, the Bank presents its assessment about the whys of Brazil did not climb the most significant spaces in the global economy. Below, we have an overview of the Bank's vision on basic education in Brazil, indicating the priority focus of this multilateral organization.

Table 1 - The system of basic education: level of training of students for the growth spurred by innovation

Features	Suggestive indicators (international comparisons)	Implications for Growth Fueled by Innovation
Access and scope	The elementary school enrollment is almost "universal" (98% in 2007), after 15 years of continuous efforts. (Brazil is above the Latin American average of 95%.)	The primary education system is still focused on expanding coverage. Now you need to redirect it to quality education, in order to tailor it to the emerging knowledge economy.
Repetition rates and dropout	The repetition rate in primary education is 28% (among the highest in the world). Argentina is 10%, Chile 1%, India 4%, the Philippines 5%, and Mozambique 26%.	The excessive high rates of grade repetition in Brazil are understandably linked to the recent expansion of primary education; however, high levels lead to distortions in age in the learning environments, generally resulting into premature evasion.
Cost of grade repetition	The annual cost of repetition of series for the budget in primary and secondary education in Brazil is U.S. $ 600 million.	The excessive repetition of grade level not only consumes a significant amount of resources, but also leads to distortions of the age gap affecting the quality of secondary education
The typical environment of elementary school	In general, classes in elementary schools emphasize memorization, repetition group, the "correct" answers, rather than conceptual understanding and thinking toward solutions. (Carnoy, Gove and	The current pedagogy adopted in the classroom is not characterized by the dynamics and interactivity that goes beyond reading and arithmetic, in order to provide children with analytical skills and innovative thinking in a future stage of their lives.

	Marshall, 2007)	
Achievement in science and mathematics	In 2003, Brazil was the last place in mathematics and science among junior in 40 countries. Brazil 40th (math), 39th (science); South Korea 3rd, 4th; Mexico 37th, 37th; Russian Federation 29th, 24th; the United States 28th, 22nd.	The exceptional performance of Brazil's inefficiency in math and science probably does not affect an elite minority of young scientists and students from private schools that are eligible to create new knowledge, however, this result affects the national capacity to use, adopt and benefit from the acquired technology.
Assessment of educational quality and student performance	In 2005, the Ministry of Education administered the Brazil Test, an assessment of learning of 3.3 million elementary school students in 42,000 schools at a cost of $ 25 million.	"Brazil test" provides a good basis for expansion and development of performance culture.
Standards	There is a lack of standards for the performance of learning and school functioning. Many schools (especially in rural areas in the poorest regions) still lack adequate classrooms, basic furniture and teaching materials.	Schools and municipal offices have not established goals and standards to streamline the performance expectations and budgetary allocation.
Computers in classroom	Computers are relatively rare or under-utilized in education. The machines tend to be used by teachers and administrators. Brazil has two computers for every one hundred students. *South Korea has 28 computers in schools for 100 pupils.*	Computers are essential to train students with technological skills. The introduction of this practice in the classroom is even more important because the families of middle and low income cannot buy personal computers for the home.

Source: World Bank (2008:176)

For the above table it is clear how much the item international competitiveness with established standards becomes the basis of the educational policy designed to Brazil by the World Bank. Another point that stands out in the review by the Bank on the Brazilian educational scenario in 2008 is the dichotomy between quantity and quality, since the rate of access to education reached most of the population, as pointed out in the first item listed. However, the quality put in subsequent items demonstrates the social fragility of this elementary schools opening of doors, without the thinking of all set of education as a real project of solid construction of a country.

> The Bank also highlights the terrible placement of Brazil in the international assessments carried out, showing thus, throughout the report, the direct relationship between the quality of national education and the projection of Brazil in international economic level. On this issue the report notes that "The Brazilian primary schools is ineffective in teaching basic reading, math, science and computing, i.e., subjects that form the base for a broader social participation in the knowledge economy." (World Bank, 2008, p.178)

FINAL CONSIDERATIONS

Thus, it is clear that international financial organizations, especially the World Bank and IMF, play roles in nuclear stimulation of Brazilian public policies both in the economic field, as in the educational field, with the consent of the national government. By proposing education as a service according to the WTO, which is being fomented and well thought out, some challenges are presented to the entire society, especially for educators: first, under guarantee of law, education is a universal right and inalienable duty of the State, in addition, human values are fundamental for community life and cannot be replaced by trade and marketing guidelines, and finally, public investment should focus not only in primary education as established in the

dictates of the World Bank . In order to develop the country and boost its economy, thus favoring the social conditions of decent living for its population, it is imperative that they direct investments from the public sector to culture, science and technology, through higher education, not leaving them in private investment and external hands.

Therefore, we perceive the web that involves the Brazilian education especially in the last three decades. The decisions, policies implemented, the directions taken, the practices disseminated are thought long before, by the multilateral agencies that hold the dictates of the rules. Would the evaluation system of national education be one of the pillars envisaged to consolidate the foreign policy of valuing competition, lifting of quantitative indexes that aim to fill external statistics? What are the real intentions in the cycle of public policies that are in-between the documents that govern the national education nowadays? What justifies the disastrous results of Brazil in international assessments even having wider access to education in the recent decades?

These and other reflections are present and they bring concerns about the ways and misdirection of the Brazilian education at all levels, especially when thinking about how commercial this right has become, which at times, is called service. Thinking of education with social quality requires much more than vacant openings and ease of access to education (hoisted flag in Brazil during the last 30 years). Education can be a factor to boost the economy of a country, but it cannot be trapped in the dictates of economic agreements, let alone having it considered in the arenas of power that do not have the social quality as a fundamental objective of its lines.

365 - Teacher Education Policies in Brazil From 1990 to 2010: The Education Course[99] in Question

Fabiana Andréa Barbosa Vaz[1] and Romilda Teodora[2]

PUCPR – Brazil
[1]fabiabvaz@uol.com.br
[2]romilda.ens@pucpr.br

Abstract: Since its creation, in 1939, the Education Course in Brazil has always been the target of studies due to its identity that has been seriously criticized by authors such as Saviani (2002, 2005), Pimenta (2002, 2006), Libâneo (1999, 2001), among others. However, this embattled situation has gotten worse because of the promulgation of the law 9394/96, which is the current law of National Education Guidelines and Basis, and the indiscriminate opening of College Education Courses, as well as the possibility of taking the Education Course in a shorter period of time, since it would prepare school administrators and also the ones responsible for the education of teachers in early years (kindergarten and 1st to 4th grades) of the Elementary School. This policy, for many authors, would be a manner to graduate teachers and also school administrators in a faster way. The same way a lot of critics and debates were postulated when the law publication happened in 2006, from The Curricular Guidelines to The Education Course and early years the school administrators, this document guides the cited course of the education of teachers in the entire country until the present moment. This assignment sought to demonstrate the policies posted in different historical moments about the formation of teachers in Brazil.

Keywords: public policies, teacher education in brazil, policies guide

This study has as its focus the teacher's education policy in Brazil from 1990 to 2010, more specifically the education of the pedagogue in Brazil. For this, we analyze the paths taken by the Pedagogy course in Brazil, which, currently, goes through a process of intense arguments, caused by the complexity of the factors that involve the human education in the current context.

This discussion is justified by the analysis made of the identity issue of the education of the pedagogue in Brazil, since its genesis until now, which permitted the realization that in the movement of the Brazilian educational legislation and of the documents resulting from meetings promoted by entities that studied this education that it is possible to indicate that they show a fragmented education of the pedagogue, corroborated by Brzezinski (1996), Saviani (2007, 2008) among others.

An analysis of the past makes it clear that, from specialists to generalists, many changes in the nomenclature, but few actual transformations were completed for the construction of the identity. The dilemma about the identity and actual function of the Pedagogy course in Brazil increased consubstantially in the 80's and, in 2011, almost three decades later, is still present and has not found a single action path, as there are many discussions about the common base of the pedagogue education and the teachers as the basis of the professional identity of all educators.

This proposal points at the search for a professional identity of the Pedagogue announcing a definition of a national curricular proposal for the Pedagogy course, for, as Dubar (1997) says "education has become a component an increasingly more valued for the access to a job and in the abandonment of jobs. If the job is increasingly central for the identity processes, the education is increasingly more connected to it" (p. 112) we cannot forget that the common base has generated innumerous discussions and publications, as in the studies by Saviani (2002, 2005), Pimenta (2002, 2006), Libâneo (2001, 2006, 2007), Aguiar et al. (2006), among others.

Studies as the one by Campos (2009), supported in Dubar (1997), show that the changes in the educational legislation allowed advances in relation to the construction of the Pedagogue's identity. Thus, with the end of the XX century, he stops having an *Inherited Professional Identity* and starts glimpsing the building of an *Aimed Professional Identity* in this first decade of the XXI century.

---

[99] In Brazil, we have a high school level teacher's course, which prepares students to teach child education and the first grades of elementary school. The pedagogy course used to be called 'college education course'.

A LITTLE OF THE EDUCATION HISTORY OF THE PEDAGOGUE IN BRAZIL

It is known that in Brazil the teaching profession is discredited, because since the colonization of the country until 1835 there were no spaces for the systematized education of the teachers in the country. At that moment, with the founding of the first Teacher's School in Niterói, there was a concern with the education of lay teachers within the context after the arrival of the Royal family in Brazil, in 1808, and later with the growing Brazilian urbanization, the increasing look for the school and the exacerbated quantity of illiterates.

The education of teachers continued being offered only as a high school level until the end of the 30's in the XX century, when, in 1939, through decree 1190 of April 4, with the formation of the National Philosophy College, the first Pedagogy course appeared to prepare the scientists in education, without clear attributions in the legislation of that time, which did not indicate a role in the school organization. The education of teachers was done in two phases: bachelor in 3 years, and one more year to give the possibility of teaching the basic subjects of the Teaching Schools (scheme 3+1). About this separation, Silva (2003:13) says that there was a "tension focus related to the separation teacher's education-high school teaching degree, reflecting the clear dichotomic conception that oriented the treatment of the two components of the pedagogic process: the content and the method."

At that historical moment there was already a problematic towards the identity of the pedagogue's profession, for the presence of pedagogues in the school was not considered a necessity. They were considered as "intellectual workers for the exercising of the high cultural activities of disinterested or technical order" (article 1, paragraph a). The issues indicated are object of analysis by Freitas (2005) when she outlined the movement by the construction of the pedagogue's education guidelines, in which she retakes an issue approached in the X National Meeting of ANFOPE (2000) and latent until today "The discussion about the pedagogue as a professional, his identity, work and education field, has been going on since the creation of the pedagogy course in 1939".

Brzezinski (1996), analyzing the teacher's education, indicates that it is not anchored only in a lack of definition, but

> allows the interpretation that the higher pedagogical studies were inferior to the other higher studies performed in the traditional teacher's education, as medicine, law or polytechnic. The duration of three years attributed to the course that prepared teachers in college education while the other schools formed their professionals in five or six years reinforced this interpretation. (p. 29)

One can also observe that some questionings followed the course throughout its history: did the pedagogy course have a unique content that could justify its existence since there was no applicability in the Brazilian work market? The "diploma of Bachelor in Pedagogy was not a market requirement, and, even to the Pedagogy graduate, the market situation was not clearly defined." (Silva, 2003, p.50)

Some entities were formed, always having the objective of discussing the identity of the Pedagogy course in Brazil. Among them CONARCFE (1983), which originated ANFOPE (1994), an association that by its studies and meetings has produced documents that serve the basis for several discussions that become opinions of the National Education Council on the Guidelines of the Pedagogy Course. CONARCFE, created in 1983, during the I CBE – Brazilian Education Conference – redefined the relationship between the bachelor's degree and the high school teaching degree, creating the idea of the educational courses, starting from a common nucleus, which would give to the students of different college education courses the understanding of the Brazilian educational problematic, a discussion about the national common nucleus that is the center of many considerations placed nowadays (Brzezinski, 1996). It is important to note, also, that this would be a "historical Mark of the movement for the reformulation of the educator's courses [...] opening the national debate on the Pedagogy Course and the High School Teaching Courses" (Pimenta, 2002, p.12).

This way, as Marques (1992:71) explains,

> The 1980's, generally considered as the lost decade, and certainly were not lost for education, if we take into consideration the emergence of the movements of educators that have, since then, restructured themselves in the country, and, especially, the attention to this relevant question, which is the education of the education professional [...].

Thus, we realize that CONARCFE, currently ANFOPE, in the 80's and 90's, becomes the producer of documents that, in national events, are studied, debated and adopted by different teaching institutions as the

central mot of the educational process of the professional for the basic education, bringing back the old discussion about: Who is the pedagogue? What does it do? What is his real work area? among others.

Libâneo (2001), analyzing the ANFOPE documents, produced in its national meetings, indicates that they contribute to decharacterize the education of the *stricto sensu* pedagogue, when they affirm that the Pedagogy course is a bachelor's degree.

However, even though these meetings and reflections concentrate on the education of the elementary school teacher, with emphasis on the education of the pedagogue, on the common national basis, fragmentation of the offered abilities or teaching as the basis of the education of every educator, different postures in relation to the Pedagogy courses in the universities remained until the 90's, always supported by the Federal Education Council, as it accepted the decisions of universities to offer this or that model (Libâneo, 2001). The decade in question became the scenery of tough discussions based theoretically on the identity posed in the prior years about the pedagogy course in Brazil.

In the political-economical ambit, the country was surrounded by the global context, which required an adjustment of the educational systems to the needs of the new order of the capital and the requirements posed for the democratization of the access to knowledge in all its levels. "The 1990's registered the presence of the international entities that participated in organizational and pedagogical terms, marked by large events[100], technical assistance and a wide production of documents." (Frigotto & Ciavatta, 2003, p.2).

In the same decade, another relevant fact increased the debates about the identity of the Pedagogy course: the promulgation of the National Educational Bases and Guidelines Law of December 20, 1996. In this law, the education of the education professionals is described in seven articles, of which these are relevant to us:

> Art. 4 The Pedagogy course is destined to the education of teachers to exercise teaching functions in the Elementary Education and in the initial years of Fundamental Teaching, in the High School courses, in the modality Education, Professional Education in the service areas and in other areas in which pedagogical knowledge is foreseen.
>
> Art. 62 – The education of teachers to work in the basic education will be done as college education, in a teaching course, in universities and high education institutes; the high school education, in the teaching modality, will be admitted as the minimum education for the teaching of children's education and of the first four grades of the elementary school.
> Art. 63. The college education institutes will keep:
> I – courses forming professionals for the basic education, including the higher teaching course, destined to the education of teachers for the child education and for the first grades of the elementary school;
> II – programs of pedagogical education for holders of college teacher's education diplomas that want to dedicate themselves to the basic education;
> III - programs of continuing education for the education professionals of the different levels
> Art. 64. The formation of the education professionals for administration, planning, inspection, educational supervision and orientation will be done in pedagogy courses or in post-graduation level, at the institution's criterion, guaranteed, in this education, the national common basis.

Even though it is not the objective of this article to analyze Law 9394/96 deeply, nor to discuss its assertions, its promulgation has opened spaces for debates in the academic world, as it brought some unexpected changes in relation to the teacher's education, the location of the education, and, besides this, according to Brzezinski (2002), Saviani (2005) and Aguiar (2002), it left room for different interpretations. Saviani (2005) analyzing articles 62 and 87 of the Law says:

> In 1996, Brazil had "5,276 Teaching Habilitations in high schools, of which 3,420 in state schools, 1,152 in private schools, 701 in municipal schools and 3 federal schools" (TANURI, 2000, p. 85). And, at college education level, there were, in 1994, 337 Pedagogy Courses, with 239 private, 35 federal, 35 state and 28 municipal (Idem, Ibidem). Thus, the education of the child education teachers and of the first four grades of the elementary school was massively done at high school level. (p. 12)

---

[100] The first of these events is the "World Conference on Education for All" in Jomtien, Thailand, from March 5 to 9, 1990, which inaugurated a large educational project, at world level, for the decade that was starting, financed by the entities UNESCO, UNICEF and World Bank.

The College Teacher's Education Institutes[101] were created by Law, art. 62, and were supposed to offer teacher's education via Higher Teaching Course to those who wanted to prepare themselves to be child education teachers and to teach in the first grades of the elementary school, which, in ANFOPE's vision, would be attending to the neoliberal market impositions via World Bank, bringing again to the national scenery the education of specialists in the fragmented optics, while leaving to the Higher Teaching Course the teacher's education. According to Freitas (1999), with this, one retakes,

> in a more elaborate level, the figure of the "specialist" pedagogue, opposed to the conception of education Professional, educator of a wider character who has in the teaching, in the pedagogical work, the basis of his education and of his professional identity. This conception of *stricto sensu* pedagogue overcome by the theoretical production of the area as well as by the democratic practice of the organization of the pedagogical work in the public schools, is linked to the conception of the "task" teacher, formed with emphasis in the specific contents. (p.21)
> For the author this conception favors
> The government policies that point to a differentiated education between teachers and the other education professionals, and gives space to the education of professionals for the management positions of the educational system separated from the school ambit, in a hierarchized perspective. In the current circumstances of the basic school, this professional is receives a new meaning from the State, maybe as a professional at its service in the school and in the teaching systems so that, facing teachers prepared with technical and pragmatist bases, may act firmly and decisively to fulfill the objectives of the reform and of the educational policies that form its basis (Freitas, 1999, p.21).

Despite the verification of this rupture in relation to the education *locus* since 1996, it was only with the publication of Decree nr. 3276, on December 6, 1999 that the College education Institutes, together with the College education Courses, would be responsible for the education of the basic education teachers. The function of teacher's education of the starting years of the fundamental teaching of the Pedagogy Course, to speed up the education of those teachers, in shorter courses in the spaces defined by Law[102].

In this path, one more aggravating circumstance to the teacher education in Brazil, the Education Institutes had the autonomy to offer the Higher Teaching course for the education of teachers for the child education and for the initial grades of the elementary education; teacher's education, for the education of teachers of the final grades of the elementary and high school and would be, according to Article 45 of the BGL, responsible for continuing education programs for the updating of elementary school teachers. Besides this, says Saviani (2005) these

> College education Institutes would be an alternative to the Pedagogy and Teacher's Education Courses, being able to do everything they do, but in a faster and cheaper manner, with short courses. This corresponds to the BGL spirit, because it participates in the same logics that had been leading the educational policy that had as one of its characteristics the diversification of the models. This way, wherever possible and there were resources, there would be full duration teacher's and pedagogy courses. However, as an alternative to this model there would be the College education Institutes. (p. 13)

Based on the aspects shown, the question is: Where is the Pedagogy course in this scenario? Since the College education Institutes and the College Teacher's course were destined to the education of teachers for the basic education, besides the BGL proposition, in its article 61 of two alternative instances to the formation of education professionals for the administration, planning, supervision and educational

---

[101] For Brzezinski (2002:78) The education colleges, already in their majority under private initiative, would become, besides others that would be created, College education Institutes and, concerned exclusively with this education, released the pressure that otherwise would fall on the public universities. It is also possible to produce less critical and questioning professionals, distant from the dynamics of research and academic debate, avoiding the formation of those who may become, using Perrenoud (1999:8) words, potential contesters, or, at least, inconvenient interlocutors.

[102] A reflection on the Higher Institutes and on the College education Course, in which market and quantitative propositions are evident, to solve government statistics to try reverting the following table, seen in 2001, besides the incentive to a private initiative, helping it to discover a new streak of labor formation: the short college education courses, since the reality in Brazil was "the country has 1,380,000 teachers, of which 779 thousand do not have a college degree; of these, 124 thousand have not finished high school and 63,700 not even elementary school." (Severino, 2001, p.184).

orientation for the elementary education (teacher's education or post-graduation), and that the teacher's training for high school level teacher's education would not have a significant demand because it has been placed in the Law as a possibility, but having the higher education as a preference (justifying the opening of such spaces in the teacher's education), this situation caused anxiety and conjectures about the identity and the disappearance of the Pedagogy course in Brazil (Silva, 2002).

> Confirming this division, article 61 suffers alterations, and, in 2009 by law 12014/2009
> Art. 61. Professionals of the elementary school are those who, exercising the profession and being graduated in acknowledged courses, are:
> I – teachers trained at high school or college level for child education and elementary and high school;
> II – education workers with a pedagogy diploma, qualified for administration, planning, supervision, inspection and educational orientation, as well as with a master's or doctor's in the same areas;
> III – education workers, with a diploma of a technical or college education course in the pedagogical area or similar.

About this legislation that directs the national education for more than a decade, Brzezinski (2002:13) affirms that "the legislation allows the wrong interpretation that the teacher is a Professional of the practice, **as though it required only the transmission of contents and not the production of knowledge through a severe investigation process." (not in bald in the original)**. And complements, **"**(...) the training of the teacher is centered in the development of competences for the Professional technical work. It is a practical, simplistic and prescriptive education, based on the *knowing how to do* for the learning of what He *will teach*" (2002:15).
In the opposite direction of the idea of the education of the pedagogue for the practice, Libâneo (2001) affirms that:

> Pedagogy is, before all, a scientific field, not a course. The course that corresponds to it is the one that forms the investigator of the education and the professional that performs educational tasks, whether a teacher or not directly a teacher. (...) the Pedagogy course can divide itself into multiple professional specializations, one of them teaching, but its specific objective is not only teaching. Thus, the Pedagogy course is not reduced to the education of teachers. (...) A consequence of this is that the basis of the educator's formation is not teaching, by the pedagogical education. Teaching is one of the modalities of the pedagogical work. (p. 60)

About the same subject ANFOPE – National Association for the Formation of the Education Professionals, which has a trajectory of interferences in the decisions about the Pedagogy courses in Brazil, being not only "a mediator of discussions about the proposals made on the education of teachers, but also as a space of curricular production" (Frangella, 2005:2). According to the author, the documents of the ANFOPEs defend for the teacher "a full education, directed to the commitment with the Brazilian education in a moment of social reconstruction, different from the figure of the graduated teacher until then" (2005:10). Complements Frangella (2005:12-13) that, according to the final document of the X ANFOPE Meeting (2000)
The curricular organization of the courses for the preparation of the education professionals must obey the following curricular guidelines:
> - teaching is the basis of the Professional education of those who dedicate themselves to the pedagogical work;
> - having the pedagogical work as the focus of the studies;
> - provide a solid theoretical education in all the curricular activities – in the specific contents to be taught by the school and in the specifically pedagogical contents;
> - provide wide cultural studies;
> - allow the contact of the students with the reality of the schools, since the beginning of the course;
> - incorporate the research as the principle of the studies;
> - create the possibility of the students experiencing ways of democratic administration;
> - develop the social commitment of the teachers;
> - provide a reflection on the teacher's education. (p. 37)

The official legislation defines through the National Curricular Guidelines for the Teacher's Education in Pedagogy (Brazil, 2006), approved by Resolution 01, of May 1, 2006, the education for the teacher's education, emphasizing in article 2 that

> The Curricular Guidelines for the Pedagogy course apply to the **initial teacher's education for the teaching of Child Education and in the initial grades of the Fundamental Education, in the High School courses, in the Teaching modality, and in Professional Education courses** in the area of services and school support, as well as in other areas in which pedagogical knowledge is foreseen. (Our emphasis)
> The current legislation specifies in the first paragraph of article 2 the meaning given to teaching.
> § 1° Teaching is understood as educational action and methodical and intentional pedagogical process, built in social, ethnical-racial and productive relations, which influence concepts, principles and objectives of Pedagogy, developing itself in the articulation between scientific and cultural knowledge, ethical and aesthetical values inherent to the process of learning, socialization and knowledge construction, in the ambit of dialogue among different visions of the world (Brazil, 2006).

Going against the legislation, Pimenta (2006) agrees with the thinking of Libâneo (2007), stressing the importance of the pedagogue professional in the school ambit, understanding that the "pedagogical doing" goes beyond the classroom, acting directly in it, thus, teaching wouldn't be the basis of the pedagogue's education, but he would interfere directly in the teaching action by orientating the practices of the teacher, making him reflect on his praxis.

> According to Libâneo (2006),
> the basis of a Pedagogy course cannot be teaching. The basis of a Pedagogy course is the study of the educative phenomenon, in its complexity, in its magnitude. Thus, we may say: Every teaching work is pedagogical work, but not all pedagogical work is teaching work. Teaching is a modality of pedagogical activity, so that the basis, the support, of teaching is the pedagogical education, not the opposite. That is, the range of Pedagogy is bigger than the one of teaching. A professor is a pedagogue, but not every pedagogue needs to be a teacher. (p. 5)

Franco (2002) reinforces the harm caused to education as a whole when the identity of the Pedagogy course is defined only in the optics of the teaching, reductionist, affirming that

> (...) the decharacterization of Pedagogy as scientific knowledge has contributed to keep it in the role that unfortunately it still has today: that is, to solidify educational practices deeply conservative, disconnected from the social-historical context, of its protagonists as well as the knowledge is transmits. The lack of scientific dialogue between theories and practices reifies, freezes the educational doing (that perpetuates itself as educational knowledge and not as knowing how to do) and this happens by the lack of constructive dialogue between the subject and the object of the action, or by the non-fermentation of the dialectics in the construction of the educative reality. (p. 182)

Thus, some questioning is necessary: If the pedagogue is the one who studies for teaching, who is the professional that will think about and investigate in a critical manner this education? (Franco, 2002). If the education of the pedagogue must be so increased, according to the guidelines (Resolution 1/2006 – Brazil, 2006), how are the High Education Institutions (HEI) are structured to attend to what is determined in the Legislation in question? What is the real interest of the discourse, understood here in the vision of Yeatman (1990, as cited in Mainardes, 2009, p.9) such as a "dispute arena", when it proposes an education of 2800 hours of educational activities and to widen the field of work of the Pedagogue, bringing teaching as the basis of its education, as determined in art. 5 of the Guidelines and presuppose that this education will supply all the needs for initial education.

> Art. 5 The graduate of the Pedagogy course must be apt to:
> I – act with ethics and commitment with the objective of building a just, impartial and equalitarian society;

II – understand, take care of and educate children from zero to five years, to contribute for their development in the physical, psychological, intellectual and social dimensions;

III – strengthen the development and the learning of elementary school children, as well as of those who did not have the opportunity of studying in the appropriate age;

IV – work, in school and non-school spaces, in the promotion of the learning of individuals in different phases of the human development, in several levels and modalities of the educational process;

V – acknowledge and respect the manifestations and physical, cognitive, emotional, affective necessities of the students in their individual and collective relationships;

VI – teach Portuguese, Mathematics, Sciences, History, Geography, Arts, Physical Education in an interdisciplinary manner adequate to the different phases of the human development;

VII – connect the languages of the means of communications to the education, in the didactic-pedagogical processes, demonstrating a domain of the Technologies of information and communication adequate to the development of meaningful learning;

VIII – promote and facilitate cooperation relationships between the educative institution, the family and the community;

IX – identify social-cultural and educational problems with an investigative, integrative and propositive posture facing complex realities, to overcome social, ethnical-racial, economic, cultural, religious, political and other exclusions;

X – demonstrate awareness of the diversity, respecting the differences of environmental-ecological, ethnical-racial, gender, generational bands, social classes, religions, special needs and sexual orientation nature;

XI – develop team work, establishing a dialogue between the educational area and the other areas of knowledge;

XII – participate in the management of the institutions contributing to the preparation, implementation, coordination, follow-up and evaluation of the pedagogical project;

XIII – participate in the management of the institutions, planning, executing, following and evaluating projects and educational programs, in school and non school programs;

XIV – perform research that brings knowledge, among others: about students and the socio-cultural reality in which they develop their non-school experiences;

On teaching and learning processes, in different environmental-ecological areas; about curricular proposals; and about the organization of the educative work and pedagogical practices;

XV – use correctly tools for the construction of pedagogical and scientific knowledge;

XVI – study, apply critically the curricular guidelines and other legal determinations that he has to implement, execute, evaluate and send the result to the competent entities. (Brazil, 2006)

In the same manner, a closer look at the Curricular Guidelines in relation to the time destined to the internships points at another incoherence, for, according to Pimenta (2004)

The internship as a field of knowledge and central curricular axle in the teacher's education courses permits that some aspects indispensable to the construction of the identity, the knowledge and the specific postures for the professional teacher be worked. (p. 61)

This way, the author agrees with Pimenta (2004) that the question of the internships indispensable to the indicial education is defined in a precarious manner by the legislation:

Art. 7º The Pedagogy Course will have a minimum of 3,200 hours of effective academic work, distributed in this manner:

I – 2,800 hours dedicated to educational activities, such as classes, seminars, participation in research, consultation to libraries and documentation centers, visits to educational and cultural institutions, practical activities of a different nature, participation in study groups;

II - 300 hours dedicated to the Supervised Internship in Child Education and in the initial grades of the Elementary School, including specific areas, if necessary, according to the pedagogical project of the institution; (...)

IV – curricular internship to be done throughout the course, to insure to the teachers to be some experience in the profession, in school and non-school environments that increase and strengthen ethical attitudes, knowledge and competences:

a) in the Child Education and in the initial grades of Elementary School, as a priority;

b) in the pedagogical disciplines of the High School Teacher's Education;

c) in the Professional Education in the area of services and school support;

d) in the Youth and Adult Education;

e) in the participation in activities of administration of educative processes, in the planning, implementation, coordination, follow-up and evaluation of educative activities and projects;

f) in meetings of pedagogical education. (Brazil, 2006)

And, as Scheibe and Aguiar (2004) say, in a text they call "Curriculum guidelines for the pedagogy course: long and incomplete", the issues mentioned show the lack of definition of the legislation in relation to the education of the teacher in Brazil. Researchers such as Franco, Libâneo and Pimenta (2007), propose elements for the preparation of curricular guidelines for the pedagogy courses.

Going further, one realizes that the official legislation proposes the education of a polyvalent professional, who has in the teaching his basis of work and education, but that offers priority to internships in teaching, leaving for last the management issues, emphasizing in article 7 that other internships, besides the ones in the initial grades and in child education, will happen in a manner that is conditioned to the pedagogical Project of the HEIs. What are the results of such curricular configuration? How prepared do the graduates feel to act in such an extensive manner? It is know that the initial education is not an end in itself. However, if it proposes an integral education, has it actually happened and has it given sufficient theoretical support for the Pedagogue's work?

Wouldn't offering to the pedagogues an education based mostly in the teaching a way of fragmentizing the teachers' education, instead of offering the HUMBOLDTIAN model of university, which foresees the continuing association among teaching, research and extension? Wouldn't it be a way to retrocede to the mere transmission, without research, without production of new knowledge, without reflection: just a training course?

Abstract: The framework which aids construction of the teaching identity of Brazilian postgraduate students is presented here in the context of an Educational Training Program. Data were obtained from postgraduate students' final reports handed in between 2000 and 2008. Two categories emerged in initial step of this investigation: teacher professionalism and teacher-student interaction. Analysis was initiated by considering teachers' attributes, professional development, and teaching conception. Were analyzed 417 replies to the question "What does being a good teacher mean?". Replies evidenced that postgraduate students attribute important elements to the development of innovative pedagogical practices concerning university teaching. Analysis also revealed that (i) conceptions of what being a good teacher is are more related to affective and emotional rather than professional aspects; (ii) the current debate on teacher professional development covers issues related to pedagogical knowledge; and (iii) the formative content must be expanded, although the postgraduation course constitutes an institutional space.

Keywords: higher education, university teaching, pedagogical knowledge.

INTRODUCTION

University has been regarded as a multicultural space with theoretical, practical, technical, political, and ethical intentionality. The processes taking place in this space allow for individuals' participation, research and construction of knowledge from previous knowledge. The experiences that confer University the status of a training place recognize that this space is a *cultural locus* that enables one to conduct intermediations of meanings among individuals under formation, thereby constructing a relations network. These relations, in turn, permit production of meanings that are influenced by the power relations present in the formation space-place (Cunha, 2009).

The production of meanings requires a new teacher profile for higher education. However, formation required for teaching at this level of education in Brazil has focused on the domain of a particular content, no matter whether it is practical (due to professional exercise) or theoretical/epistemological (due to the academic exercise or "academic ethos"), which leads to academic work being fundamentally identified with research (Pimenta, 2002).

It can be verified that universities, mainly the public ones, hire teachers for their skills as researchers. However, despite their specific knowledge, these teachers do not have professional teaching expertise. As a consequence, their teaching practice is more based on the reproduction of their experience as students rather than on the meaning of what being a teacher for Higher Education is. Several authors (Bédard, 2009; Cunha, 2010, 2009; Cunha & Broillo, 2008; Pimenta, 2009; Pimenta & Anastasiou, 2005; Ribeiro, 2009; Tardif & Lessard, 2008) argue that many solutions to the teaching problems encountered in universities lie on the pedagogical nature of teaching. In other words, to face the current challenges regarding teaching at Higher Education level requires that university teachers hold a type of knowledge that is regarded as being of low academic prestige in the scenario of current educational policies.

University teachers recognize themselves by their initial formation. The professional legitimacy of their practice as doctors, engineers, or statisticians, for instance, give rise to knowledge appreciated by the educational institution and has varying degrees of approval, depending on the negotiations and curricular struggles at the core of their respective professional community. Lucarelli (2000) says that power and prestige do not come from university teaching as pedagogical knowledge, but from dominating a determined scientific, technological or humanistic field. Therefore, it is evident that University teachers are met with an

extraordinary challenge, in order to transpose positions oscillating between two poles, namely the pole that sees the academic professional as someone who caters for more than the original disciplines, and the pole that views specific knowledge as determinant of occupational identification.

Teaching is a complex task that demands knowledge of different natures. This knowledge is based on both the culture in which the teacher is produced and the theoretical understanding that enables these professionals to justify their choices. If in the past the teaching profession was based on objective knowledge as in the case of other professions, nowadays control of this knowledge *per se* is insufficient, since the learning context is no longer the same. In *stricto sensu* courses, the fact that attendants will possibly teach in higher education courses is not prioritized. Indeed, *stricto sensu* courses emphasize knowledge about content and investigations in a specific knowledge area. Consequently, the teaching exercise experienced by postgraduate students during their formation is insufficient to form a professional that will have to deal with the "articulation of teaching with research, which makes the so repeated expression about the indissociability between teaching, research, and extension become an empty refrain, decanted without the exercise of criticism"(Gatti, 2004, p.433).

In the view of Tardif and Lessard (2008), knowledge that serves as teaching basis, as seen by teachers, is not limited to the well defined content that depends on specialized knowledge. In fact, such knowledge should cover a variety of objects, issues, and problems related to their work. In this sense, professional knowledge follows an epistemological definition (temporal, plural, heterogeneous, and cognitive); reflects culture and thinkings; and carries the characteristics of the context in which they operate. The authors emphasize that the relation between teachers and knowledge is not merely a function of transmitting knowledge that has already been built, because teachers are continually producing "specific and tacit knowledge from professional formation, courses, curricula, and their experience, which are constantly mobilized, constructed, and reconstructed "(p.81).

In this sense, Cunha (2010) argues that "being a teacher is not a task for neophytes, because the knowledge multiplicity that comes into play during their formation requires a dimension of completeness that departs from the expertise logic (...)." According to this author, teaching practice requires multiple competences that need to be appropriate and understood in their relations. These competences correspond to a matrix related to the educational field and is explained on the basis of specific teaching knowledge. The latter consists of *knowledge related to the context of pedagogical practice*, including knowledge related to the school as a social institution and to the educational and curricular policies in a given space and time; *knowledge related to the relational and collective dimension from the work situations and the formation processes*, which refer to the partnerships that the teacher establishes with their colleagues and other professionals involved in education; *knowledge related to the learning ambience,* which covers aspects related to knowledge about the students' learning conditions and the multiple linkages with social practice; *knowledge related to the students' socio-historical context*, which encompasses the skills as well as the teaching and learning processes that the teacher develops in a particular historical and social context, aiming at student learning; *knowledge related to the planning of teaching activities*, including the delineation of goals, contents, methods, teaching strategies, and proposals for the development of an effective pedagogical practice; *knowledge related to lesson execution in its multiple possibilities*, which involves the conditions that allow teachers to exercise their intellectual leadership among their students since teachers have access to cultural properties, anchored in cultural, affective, and cognitive structures; and *knowledge related to learning evaluation,* which contemplates technical knowledge about tools and evaluation strategies used by the teacher, which in turn enable students to achieve significant learning as well as review their trajectories. (Cunha, 2010).

The University structure almost always revolves around the individual axis (class, research, publications, formation, etc.), thus defining the teaching practice. Therefore, universities' initiative of including pedagogical formation in postgraduation programmes is still considered a timid attempt in view of the problem of University teacher identity construction in a context where research is seen as critical to the teaching exercise. According to Dubar (2005), human identity is not given, but is constructed and reconstructed throughout life. Among the most important events contributing to the construction of an individuals' social identity are leaving the school system and confronting the professional world, which are critical periods for identity construction and are configured as social and professional.

Teacher identity "is the result of complex social interactions in contemporary societies and socio-psychological expression which all affect an individuals' learning, cognitive processes, and actions. It defines an individual´s place in the world at any given time, in any given culture, in any history."(Gatti apud Brzezinski, 2002). This implies that University teachers should have a formation that includes knowledge about scientific research, pedagogy, and constant updating, which demands solid formation not only in terms

of the contents related to their own scientific area, but also in terms of the aspects related to pedagogical knowledge and other dimensions that characterize teaching.

Pimenta (2002) identifies the emergence of the question of knowledge as one of the aspects considered in studies on the identity of the teacher profession. The author argues that identity is constructed from

> "(...) the social significance of the profession, the continuous review of the social meanings of the profession, the revision of traditions. But also from the reaffirmation of culturally based practice that remains meaningful (...) from the confrontation between theory and practice, the systematic analysis of practices in the light of existing theories, the construction of new theories (...)" (Pimenta, 2002, p.19).

In other words, the author recalls the importance of considering the teacher in their own formation, in a self-formation process, in the redesign of their initial knowledge on the basis of their practice, so that their knowledge will be built from a reflection on and about practice.

Bédard (2009) points out three pedagogical trends that currently form the basis for higher education and somehow affect the formative context of the higher education teacher. The first trend, consolidated in North America and underway in Europe, suggests that the undergraduate courses should prepare students to confront the job market and that their future professional role implies job search and career management. The second trend, identified in North American higher education institutions, reconfigures the recognition system of teaching quality in universities and considers that teaching formation and pedagogy are very important for doctoral students interested in a teaching career, apart from providing support to faculty members currently involved with teaching. The third and last trend consists in the movement that aims to establish courses focused on learning and active approach methods. The author stresses that there are studies assessing the impacts of these trends on education and research, in view of the current higher education situation and the teaching staff tradition, characterized by academic freedom. He adds that

> "(…) opening the doors of higher education institutions to the realities of the professional market should not repeat the Trojan Horse story (...) One should not aim only at a contextual teaching for their own benefit, which could conceal important issues related to the University purposes." (Bédard, 2009, p.147).

In view of what has been explained above, the complexity of the teaching profession should be borne in mind when it comes to *stricto sensu* formation courses, in order to aid understanding of the interplay between teaching and research, which are both involved in the exercise of higher education teaching.

METHODOLOGICAL PATHS

The final reports handed in by postgraduate students attending the postgraduate course "University: Formation, Learning and Knowledge Production" offered between 2000 to 2008, were used as corpus for document analysis (Cellard, 2008; Bogdan & Biklen, 1997). This course is part of the Learning Improvement Program (LIP) implemented in a Brazilian state university.

The main aim of the Learning Improvement Program is "to improve the formation of the postgraduate student concerning their teaching stills". This program consists of two phases, namely, pedagogical preparation and supervised teacher training. (Pró Reitoria de Pós-Graduação, Portaria GR 3588). According to the ordinance that regulates this program, the pedagogical preparation step has different characteristics, because the teaching units of the university can organize it in three different ways: by offering course credits, by promoting condensed conferences, or by proposing a core of activities always coordinated by a teacher. The latter activities could involve preparation of pedagogical materials, and discussions about course curriculum and syllabus. As for supervised teacher training stage, students should work six hours per week exclusively teaching to undergraduate courses. The training could be carried out in the form of seminars, lab experiments, guided study and small group discussion, organization of and participation in shifts for the tutoring of undergraduate students, and application of tests and exercises. Note that postgraduate student participation in the LIP Program is optional, but students who have been granted with scholarship from the Coordenação de Aprimoramento de Pessoal de Nível Superior (CAPES, Coordination for the improvement of Higher Education personnel) have to attend it as a compulsory discipline.

Answers to the question "What does being a good teacher mean?" were analyzed in the final reports handend in by postgraduate students who attended the postgraduate course *University: Formation, Learning and Knowledge Production* between 2000 and 2008, using the content analysis approach (Bardin, 2002). It is

difficult, in fact almost impossible, to define a "good teacher" because we can fall into a reductionism based on competences. So it is more appropriate to outline some notes that can help us reflect on the teaching activity. In this sense, Nóvoa (2009) can provide valuable contribution by pointing out five essential features for the definition of teacher professionalism: "(...) knowledge, professional culture, pedagogical tact, teamwork, and social commitment" (p.30-31).

During the first phase of this study, "floating reading" of the reports delineating the formation of the *corpus* was accomplished. In the second phase, the material was explored, and the raw data was encoded in text comprehension nuclei. Two categories emerged from these nuclei, namely teacher professionalism and teacher-student interaction. It is noteworthy that, for the purpose of this text, only the category *teacher professionalism* will be approached.

Cáceres Mesa (2003) conceptualizes *teacher professionalization* as a permanent acquisition, organization and knowledge restructuring process that provides teachers with values for the development of their teaching function. Imbernón (2009) conceives *professionalization* as a complex social and multidimensional concept, based on the cooperation values established among the concretely situated individuals. In Gimeno Sacristán´s view (2002), *teacher professionalism* is a set of knowledge, values and skills developed throughout a learning process.

Given the complexity of the professionalization concept, we chose to analyze it from three dimensions, namely Teachers' Attributes (TA), Professional Development (PD), and Teaching Conceptions (TC). Among the 417 documents selected for analysis between the years 2000 and 2008, 334 belonged to the three mentioned dimensions (TA, PD, and TC).

Reading of the documents and their organization by dimensions brought new perspectives to the issue of teaching, which somehow expresses the conceptions and representations of reports written by the postgraduate students. The TA dimension appears constantly and is addressed in 83 reports, as can be seen in Table 1.

Table 1: Frequency of dimensions for the category "Teacher Professionalization".

dimensions	2000	2001	2002	2003	2004	2005	2006	2007	2008	total
Teachers' attributes	12	15	17	12	7	16	4	-	-	83
Professional development	7	6	6	12	4	20	12	5	7	79
Teaching conceptions	17	20	25	26	24	76	28	19	20	255

These results are consistent with the literature produced on the formation of University teachers. Different researches have shown that most University teachers do not have pedagogical formation, since their academic career emphasizes specific knowledge in their training area as being the most important.

Teaches' Attributes (TA) Dimension

The TA dimension corresponds to individual characteristics, acquired along one's personal and professional trajectory. TA shows the real level of teachers' development as producers and precursors of their potential development, through interactivity. According to the Bioecological Model (Bronfenbrenner & Morris, 1998 apud Morosini, 2006, p. 374), in order to understand this interactivity it is necessary to consider three sets of individual characteristics that form a person's structure throughout their development process: measures, resources, and demands. Some strategies facilitate this action, such as research work, creation of projects of social and cultural interest, access to new technologies, and motivation for development of a partnership between teacher and student. The report below explains the meaning that students attach to the TA dimension:

> *A good teacher is one that arouses the interest in certain points through a stimulation process, guides the path to learning, creates the enthusiasm necessary for learning to take place through their own enthusiasm, shows the importance of the main aspects of knowledge and of the subject's goals. A good teacher is in love with what they do (...) (22/2001)*

This fragment, appointed by the postgraduate student, represents a set of skills, attitudes, and values derived from his/her social representations. In this scenario of complexity, contradictions, and constructed experiences, we illustrate Seddon's contributions, which features the professional action (*capacity-building*)

associated with personal characteristics and refers to "TA" as contextual sensitivity, collective or caring democratic values, community engagement, recognition of public diversity and effort to publish the achievements, organizational orientation, learner-centered pedagogical beliefs, optimism and stimulating good mood, and flexibility to work with students. (Seddon apud Tardif & Lessard, 2008).

The above mentioned features raised by Seddon reinforce the idea that dominating the contents of one's action area, and an enthusiastic and missionary attitude are not enough for teacher professionalization. It is necessary to have someone who acts as protagonist and is always trying to improve their skills, aims at something other than the *status quo*, and is more critical, alert and interactive.

Teaching Conception (TC) Dimension

The TC dimension arises from the fact that teachers are able to perceive themselves as a unit in which the person and professional determines how to be a teacher. In the pedagogical dimension of University teaching must be invested, so that, more time this pedagogical knowledge that teachers need to hold is improved, apart from updating the knowledge concerning their specific area. New pedagogical knowledge that teachers need to acquire concerns the basic principles of the teaching-learning process and of the curriculum. The fragment below corroborates the author's thought, to the extent that it conceptualizes the teacher as a professional who

> (...) presents a reality for the student, challenges them, and arouses in them the desire and interest to learn. The teacher should know and understand the content that they are teaching, identifying arguments for and against the content. The teacher has to start from the students' prior knowledge and then introduce new elements for analysis. The teacher must be able to use their knowledge and experience to develop their current practices. (01/2007)

Student's understanding about the several dimensions of teacher performance in higher education is undeniable. The demand for professionals to acquire knowledge about University teaching in the context of pedagogical knowledge, experience knowledge, and the elements of interpersonal relationships in the teaching and learning process can be noticed. However, although these reports demonstrate the contribution of the Pedagogical Preparation Step of the Learning Improvement Program to the formation of these future University teachers, it is clear that the conceptions of learning how to teach through practice are still deeply entrenched in individuals, and the pedagogical sciences theories are neglected, so that research is prioritized at the expense of teaching practice. These ideas agree with the opinions expressed in the literature, among which the studies of Pimenta (2009) are worthy of mention. According to this author,

> "In most higher education institutions, including universities, teachers have significant experience and even years of study on their specific areas, in contrast with their lack of preparation and scientific ignorance about the teaching and learning process, for which they are responsible from the moment they step into the classroom." (Pimenta, 2009, p. 51)

It appears, therefore, that being recognized as a researcher in the production of significant additions to existing theoretical frameworks is no guarantee of excellence in teaching performance. Research and knowledge generation are the goals of postgraduation. "When they participate in postgraduate study programs, teachers systematize and develop skills typical of research methods." (Pimenta, 2009). Modern society has demanded that this thinking and the conception of what being a University teacher is are changed, so that the University teacher transpasses the specific content domain and a teacher who understands his role as a University lecturer and who knows about the relationships established between students and knowledge emerges.

The current University context no longer regards the teacher as a transmitter of knowledge. Zabalza (2004) points out that today's challenge in the case of University teachers lies on becoming a facilitator of students' learning, since the multiple possibilities of access to knowledge require assistance for decoding assimilation, appropriation, and linking with the professional practice, in a clearly formative dimension. Almeida et al. (2004) highlight that conducting mediation between students and knowledge, responding to the specific needs of the diverse student profiles, and working contexts is at the heart of University teachers' pedagogical actions. Therefore, both models preserved in the representations of teachers as the idea that teaching is an art that is learned with practice are not sufficient to sustain the needs of University teaching. As a consequence, this scenario brings the need to shape a major renovation in the context of the classroom and methodologies of University education.

Rué and Almeida (2009) argue that "the formation of teachers needs to be part of a professional development process, in order to promote articulation between the circumstances of work, the theoretical references arising from pedagogical thinking, and the practical experience of those involved with the educational routine." This personal growth does not occur in an abstract way and requires a well defined and relevant framework of professional competence in order to better target those who are responsible for the formation and the trainees. Difficult tasks are presented to teachers, all of which demand teacher formation programs aimed at providing access to concepts, guidelines and tools that allow teachers to plan, develop and evaluate the teaching-learning process according to the reconfiguration of the social and learning needs.

Professional Development (PD) Dimension
In the current literature about teacher formation processes it is very common to find *Teacher Formation* as a synonym of *Teacher Professional Development* (Pachane, 2003).
Benedito, Ferrer, and Ferreres (1995) understand *professional development* as

> "(…) any systematic attempt to improve the practice, beliefs, and professional knowledge, with the aim of enhancing teaching, researching, and management qualities. This concept includes the diagnosis of current and future needs of an organization and its members, and the development of programs and activities to fulfill these needs." (Benedito et al, 1995, p. 131).

Pimenta and Anastasiou (2004) state that professional development involves initial and continuing formation, articulated with a process of identitary and professional appreciation of teachers. For other authors who treat the subject, like Canário (2005), Rué (2004), and Marcelo (2009), the teacher formation journey is characterized as a continuous process of professional development, which combines basic formation prior to the performance, such as that resulting from other situations of formal specific knowledge acquisition, with the construction and reconstruction of everyday knowledge and the professional act.
It is noteworthy that the PD dimension includes a set of activities aiming to improve the thinking practice, knowledge and professional skills concerning continuous education. These formative activities may be carried out from different perspectives and are pictured in the reports of postgraduate students:

> *A good teacher seeks continuous formation through courses, readings, debates, seminars, and reflection on practice and is not somenone who is only bound to the traditional method, always functional, and gives purely theoretical lessons where the student is a passive individual.(2007/14)*

DP moves through a personal dimension where "formation should encourage a critical and reflective perspective that provides teachers with a means of conducting independent thinking, thus facilitating the self-formation dynamics (...), contributions to professional emancipation and consolidation of a professional that is autonomous in the production of their own knowledge and of their own values "(Nóvoa, 1992).
The analyzed data suggest that professional development is understood by postgraduate students as a constant process of innovation, updating, and discussion. The students also pointed out that a "good teacher" must have a proactive approach in relation to their professional development. Moreover, educational institutions need to offer in-service continuous formation programs that include offering pedagogical formation to teachers, which is necessary for their professional exercise.

CONCLUSION
The initial content analysis, in the three studied dimensions, indicate that students attribute important elements to the development of innovative pedagogical practices regarding University teaching, namely: i) the conceptions of what being a good teacher is are more related to affective and emotional than professional aspects, ii) the current debate on teacher professional development covers issues related to pedagogical knowledge, even though they have not been recognized in the past; iii) the course, although it constitutes a major institutional space for the training of future higher education teachers, needs to expand its formative content because students have a positive representation in relation to University teaching.
Therefore, we propose that courses should include disciplines related to pedagogical formation such as learning programs, pedagogical projects, teaching strategies and new technologies, curricula discussions; as well as criteria and tools for evaluation from the formative perspective. All this can contribute to the construction of the teacher identity in postgraduate students, for which research, extension, and education should play an important role during University teaching practice.

Abstract: The teaching of geometry has changed its methodological guidelines. For various reasons many primary school teachers do not have an education to respond to current demands. In this study the didactical knowledge of two primary school teachers, Ana and Inês, is analysed concerning geometrical topics and the relationship that exists between this knowledge and their education using a qualitative methodology. Data was collected through four classroom observations of each teacher and two semi-structured interviews.

In relation to curricular knowledge both teachers are aware of the content and the reformulations of the syllabuses but they do not put their knowledge into practice. They have some difficulties in respect of their knowledge of some content of geometry, such as the notion of volume. In respect of instructional knowledge Ana develops strategies that promote the participation of her students, while Inês demonstrates to be an expository teacher. Their didactic knowledge seems to relate to their initial education.

Keywords: Geometry, Didactic Knowledge, Teacher Education.

INTRODUCTION

Current reality indicates a world where actual information of a mathematical nature is ever more obvious in everyday life. Social and professional requirements demand specific competencies and especially knowing how to use mathematical knowledge efficiently. The school, therefore, plays an important role in the education of their students for a responsible, informed and critical citizenship. However, a gap still persists between what is taught and the use of what is taught. This gap is such that the NCTM (1991) defended the teaching of school mathematics - in particular geometry - integrated and taken up in normal life, whereby the students "must develop habits of thinking mathematically and understanding and appreciating the role of mathematics in human life" (p. 6).

The importance that geometry has in the school curriculum results, according to Abrantes (1999), from it being a subject that develops the reasoning capacity of the student, a sensitivity for understanding real world phenomena and the use of geometrical ideas in various situations. Actually, this subject appears in syllabuses at various levels of teaching though successively changed throughout time. In the reformulations of current school syllabuses, the teachers are the "main figures in the changing processes by which mathematics is taught and learnt in schools" (NCTM, 1994, p. 2). However, for various reasons, these reformulations are not always understood in the same way by all teachers. One of these reasons derives from acquired education, which can contribute to the existence of difficulties and gaps in the knowledge of the teachers that do not help with the fulfilling of the actual recommended methods for the teaching of geometry. This idea is reinforced by Monteiro (1992), when she affirms that the past of almost all mathematics teachers in respect of how they developed their learning, indicates and determines the way that they perform their practice of teaching. For Ponte (1999), this practice highlights the didactical knowledge of the teachers that has been developed throughout his education and which plays a crucial role in the course of his practice of teaching. The teacher can develop this knowledge when he takes decisions related to the most appropriate way of establishing the relationship between the student and the mathematical knowledge to be tackled, when he takes advantage of the resources that he has at his disposal and when he draws conclusions from his teaching activity. Considering that this type of knowledge determines the manner in which the teacher deals with the methodological guidance recommended by the school syllabuses, we seek to analyse the didactical knowledge of two primary teachers about the geometric topics of this cycle and the relationship that exists between this knowledge and their education.

GEOMETRY IN THE MATHEMATICS CURRICULUM OF THE FIRST CYCLE

For the origin of geometry it is necessary to go back and "drink" in the sources of ancient civilizations like, for example, the Hellenic and from these far-off times imagine oneself distinguishing between them in the context of every time mathematical knowledge has become deeper and more distinct. Great figures of geometry have spanned history expounding diverse theories, as is the case of Euclidian geometry, which is still in force in present day school syllabuses. However, the teaching of this subject has been developed many times from the point of view of it being a mere abstraction resulting in a logical system, where all the results derive rigorously from definitions and axioms and, at times, given more emphasis to memorisation of definitions and techniques of calculation (Gomes & Ralha, 2005).

During the last century large transformations in the educational approach of geometry occurred, of which one can point to the major reform of mathematics around the sixties, which was helped by the structuralist and constructivist theories of Bruner and Piaget, who influenced the form of conceiving the teaching of Mathematics. For Veloso (1998) the reduction of the importance of geometry in the curriculum owed itself to the 'modern mathematics' movement, which thought geometry was a 'poor parent' of linear algebra. In Portugal, as a consequence of this reform in primary teaching, the aspects related with observation, experimentation and construction almost disappeared. The development of essential competencies, such as a fundamental spatial capacity for future learning that were related to geometrical knowledge, was neglected. From the perspective of this author, generations of students, many of them current teachers of mathematics, "underwent mathematics teaching having contact only with elementary geometry in the form of the Theorem of Pythagoras and some formulas for calculating areas and volumes" (p. 23).

Later - in the seventies - people begin to value school geometry again and - particularly in the last decade - to carry on discussions about a growing coming together between mathematics and reality. Appealing to realisation and visualisation and - in a systematic way - resorting to the manipulation of materials, Abrantes (1999) considered that the learning of geometry fitted into the current process of teaching and learning, which is intended to help in the construction of useful working knowledge through discovery and problem solving from the most elementary school level. Throughout schooling, it is now particularly advised that the teaching of geometry should favour its interpretation and participation in the surrounding world by including the visualisation of objects, the representation and manipulation of these representations, the creation of new objects and the integration of problem solving that relates the application of geometry to daily situations. In the first years of schooling it is recommendable that the teaching and learning of geometry should start from flat surfaces and favour exploration, manipulation and experimentation by using everyday objects and other specific materials (Ministério da Educação, 2007). An opportunity must be given to the students to make observations, write descriptions and draw representations of objects, configurations and routes in order that they are stimulated to act, preview, see and explain what is conveyed in the space that they perceive with the objective of progressively developing their capacity of reasoning about mental representations. Equally important are considered experiences that involve the construction and deconstruction of figures accompanied by descriptions and representations.

DIDACTIC KNOWLEDGE

Nowadays, a growing preoccupation with the importance of the influence of investigation in learning is such that it is noticeable that teachers are accumulating, through the exercise of their educational activities and while integrating these elements into the professional knowledge, influences over what they teach and how it is taught (NCTM, 1994). Serrazina (1999) calls attention to the difficulty of distinguishing the mathematical knowledge of the teacher from the knowledge of mathematics that he teaches owing "to their beliefs and conceptions about mathematics and their teaching" (p. 140). According to Vale (2000), the knowledge of the teacher "is no more than his personal knowledge developed during all formal and informal experiences that have happened throughout his career from initial education to retirement" (p. 104). Nevertheless, this concept of the knowledge of the teacher, which is both general and wide-ranging, can be understood differently and, at the same time, can be sub-divided into different types of knowledge. Shulman (1986) considered that a teacher needs specific knowledge in order to teach. The author have organised this knowledge into content knowledge, curricular knowledge and pedagogical content knowledge.

In relation to curricular knowledge, Shulman (1986) considered it to be knowledge that the teacher possessed in relation to the syllabuses of his disciplinary area, to the variety of materials that can be used in his teaching, as well as the advantages and disadvantages of the use of these syllabuses and materials in his professional activity. The author consider, as relevant factors in curricular knowledge, content knowledge that the students learn in other subjects by way of articulating with the content that is being studied in their

classes (horizontal knowledge) and knowledge of the content of their area at distinctive school levels and of the materials that can be used in teaching this content (vertical knowledge).

Regarding content knowledge, Shulman (1986) said the question of knowledge is that the teacher must have content to teach, as well as knowledge of its organisational structures, which is mostly of a substantial nature, a variety of ways of organising the basic concepts and principles of a subject like its syntax that is a set of rules that determine what is true or false in the field. For Shulman to teach a given subject, besides knowing the facts and concepts that are to be presented, it is not enough to know that 'a given thing is like this' but why it is like this. Content knowledge is a determinant in the selection of the tasks of teaching, in decision-making about how and when to tackle a given topic, in establishing connections between the topics approached, in guiding the activities of the students, in listening to and commenting on their ideas and for determining the validity of a mathematical argument.

Regarding the knowledge that the teacher has of his students or more specifically about the ways that they learn Travers et al. (1977) set out three levels of learning: knowledge, understanding and problem solving, which presuppose an increasing gradation of complexity. It is necessary overall that the teacher has in mind these levels of learning when broaching the content with the students, because, if the knowledge can include memorisation or repetition as facilitating strategies, right away understanding and problem solving require the main attention of the teacher in the selection of appropriate strategies for success in school. In the case of understanding it will be necessary to take account of strategies like interaction, discussion or discovery learning. Regarding the higher level of problem solving the teacher should favour a diversity of problems and allocate sufficient time for each.

Of the various types of professional knowledge, Shulman (1986) pays special attention to pedagogical content knowledge, due to its scope and consequent acceptance of responsibility that falls back on the teachers. This knowledge embraces not only the knowledge that the teachers hold about the mathematical content to teach but also the pedagogical procedures prone to strengthen the process of teaching and the learning of the students, thereby in this way linking together theory and practice.

The work of Shulman about the knowledge of the teacher contributed to research about the greater importance of content knowledge in teaching rather than general knowledge. However, there are authors that offer some criticisms of the importance that Shulman gives to pedagogical content knowledge, which is more attacked for a declarative conception of the knowledge of the teacher than for a conception of knowledge oriented towards action or included in practice. Ponte (1999) considered that the knowledge necessary for the teacher to be able to teach integrates other elements besides content knowledge and pedagogical knowledge. For example, Ponte and Chapman (2006) stress emotion, motivation in teacher activity and the relationship between content knowledge and knowledge about the students and the curriculum.

The didactic knowledge, which the teacher develops throughout his professional path, guides his actions so that the students should be interventional elements in the activities that they carry out in and for the classroom.

THE PROFESSIONAL DEVELOPMENT OF THE TEACHER

The particularity of contemporary society is reflected in the questioning again of the school and educational actions and also mathematical education, especially, as stated by Loureiro (2004), because methodologies and curricular syllabuses have gone through - in recent decades - very significant alterations. For Gomes and Ralha (2005), the new methodological demands, which derive from the alterations of school syllabuses, generate difficulties that seem to intensify, when a deficient teacher education is encountered in relation to mathematical content. These authors considered that initial education is not enough and that permanent updating is necessary throughout the professional career of the teacher. Yet initial education must offer "the future teachers a mathematical education that prepares them for teaching for the understanding of mathematical ideas and concepts and for the development of reasoning and communication" (Loureiro, 2004, p. 89). After initial education the professionalization of the teacher will be guaranteed through courses and programmes that involve a range of competencies in harmony with current curricular guidelines and the functions that the teachers perform in schools (Pereira et al., 2007).

Some studies about the knowledge of primary teachers about geometry show scarcely encouraging knowledge of the results. Gomes and Ralha (2005) in studying the teaching of geometry in the first cycle identified "at the least a distressing ignorance at the level of scientific knowledge about so-called elementary geometry" (p. 19). In this same sense the APM (1998) declared - by evidencing the deficient initial education of primary teachers concerning mathematics - that teachers that underwent their Professional education in the context of the Primary Mastership "had a very precarious initial training in mathematics in relation to education and the didactics of mathematics" (p. 70). The study carried out by Fonseca et al. (2002) showed a

clear discrepancy between the level of knowledge that the teachers revealed in relation to the content of geometry and the content of other mathematical topics. At the same time the teachers who had a more specific education coming from teacher education colleges did not present a very different situation. The possibility of opting for several course variations during education led to some of the teachers having an even more reduced knowledge of the area of mathematics (APM, 1998). Other studies corroborate the gaps in the level of mathematical content knowledge of the teachers. In the case of the study by Matos (1985) about the level of geometrical competencies of preservice teachers in the light of the theory of van Hiele, the majority of participants in the study did not achieve or surpass Level 2, which should be seen as the capacity to identify the elements and properties of geometrical figures through observation and experimentation.

The preoccupation with the quality and adequacy of the teaching activity has itself been shown in numerous important studies of primary teachers. This interest derives, according to Almiro (1999), "from the recognition of their essential role in the changes that are important to undertake in the processes by which this subject is taught in our schools" (p. 25). Gomes and Ralha (2005) consider that the education of primary teachers must be strengthened in terms of its educational intentions. The striking characteristic in the early learning of the education of individuals throughout life suggests that teachers of this level of teaching should be responsible for the basic education of the students, which will constitute their future cognitive mathematical representations.

METHOD

This study analyses the didactic knowledge of two primary teachers about topics of geometry handled at this school level and the relationship that exists between this knowledge and their education. With this objective a case study was developed about Ana and Inês. These teachers were selected as they teach in the same school in classes composed of children in two different years of schooling. Ana teaches in the first and second years of schooling and Inês in the third and fourth. Both have been teaching for more than 20 years having completed education courses with an emphasis on "expressive arts" and "educational guidance," respectively, and at the moment are attending an in-service education course in the area of mathematics.

The study follows a qualitative and interpretative methodology in order to understand the significance that these teachers give to the actions in which they are involved (Bogdan & Biklen, 1994). The interpretative approach seeks to understand and explain a given reality based on an analysis of a particular and specific body of information and observed data, which determines the "personal role of the investigator" (Gómez et al., 1999, p. 34). As the subjectivity of the investigator can call into question the credibility of the information collected, in order to become objective, this type of approach resorts to a set of measures, such as a detailed description susceptible to allowing the "particularity of the situations to permit an exhaustive and complex description of the actual reality of the object under investigation" (p. 35). The case study is characterised by Bogdan and Biklen (1994) as "the detailed observation of a context, an individual, a unique documentary source or of a specific event" (p. 89). Yin (2001) also mentions that case studies constitute the appropriate method of research in the search for relationships and when the investigator wishes to include a certain phenomena in the context in which it occurs.

Data was collected from four class observations (CO) by each of these teachers ($CO_i, i \in \{1,2,3,4\}$) and from two semi-structures personal interviews (PI). Class observation is understood by Yin (2001) as a data collection technique that permits the bringing together of straightforward information about the behaviour of the participants. In this case, the information about the practices of the teachers under treatment was collected and - based on this - aspects of didactic knowledge of the teachers about the content of geometry were deduced.

An interview is defined by Bogdan and Biklen (1994) as "an intentional conversation, generally between two people, (...) directed by one of them with the objective of obtaining information about the other" (p. 134). It is not used to know the individual himself but to take the individual as an example of a given community. In this study, the interview made it possible "to collect descriptive data in the own language of the subjects, thus permitting the investigators to intuitively develop an idea about the manner in which the subjects interpreted aspects of their world" (Bogdan & Biklen, 1994, p. 134). The first interview (I1) was composed of questions about geometrical topics from the current mathematics syllabus for the first cycle of Basic Education. The second interview (I2) focussed on the classes observed.

KNOWLEDGE ABOUT THE CONTENT OF GEOMETRY

Ana and Inês disclosed that they had consistent knowledge about the content of the geometry that they teach, as shown in the example of the hierarchy of quadrilaterals. But they also revealed some difficulties in relation to the significance of concepts. Ana did not like estimates and solving problems about areas and volumes, as exemplified by the way she compared the volume of two cylinders obtained by rolling up an A4

sheet of paper according to each one of its sides. She thought that the cylinders "would hold the same quantity of liquid, as the sheet is the same" (I1). The same surface of the sheet prevailed in relation to the variation of the area of the base and height of the cylinders obtained.

She provided a similar reasoning when comparing the volumes of boxes obtained by cutting equal squares out of the corners of the same A4 sheet.
Figure 1: Construction of boxes from an A4 sheet of paper.

As for Ana, the volumes of the boxes "are different," though she had difficulties in her justification, thinking that box A is bigger than box B, because more paper was cut out of B" (PI1). The area of the base prevailed in relation to the height of the box.

The teacher was conscious that the difficulties that she had with some content influenced her teaching. For example, the difficulty, which she had about the notion of volume, led her to state that "I do not like teaching volumes very much, the students do not understand, as it is very abstract" (PI2).

Inês also manifested some difficulties with volumes. In relation to the volume of cylinders, she considered that "the sheet of paper is delineated by the same surface, so for me the volume is actually equal" (PI1). As for the volumes of the boxes, she affirmed that "they are different; the surface of box A is bigger than the surface of box B, because more paper has been taken from B, so we also have to take internal volume from this box" (PI1). This teacher tended to highlight the application of formulas the other way round in relation to the data furnished: "if we assign measurements to the squares that we cut out, the application of the formula can be seen later" (PI1).

Inês also is conscious that the difficulties that she senses in the content of geometry influence her classes: "I have gaps of knowledge in geometry that are complicated to overcome and explain to others, so I have to be aware of these things to fix them" (PI2).

Besides their difficulties with three-dimensional ideas, the teachers also showed difficulties about two-dimensional ideas, as is verified in the following tessellation:
Figure 2: Tessellate the plan.

Ana as asserted that the "pattern unit is the triangle" (PI1) but she did not explain the transformations that permitted tessellate the plan from this figure. Inês considered that the "pattern unit is the hexagon and the tessellation is only repeating the same figure" (PI1).

In another problem about the best position for the construction of a petrol station equidistant from two localities, the teachers did no more than to identify the position corresponding to the middle point of the segment, which linked these two localities, as exemplified by the affirmation of Inês: "design the villages, link them with a line and then divide it in half and it is here that the petrol station must be built" (PI1).

In the observed classes, both the teachers had good knowledge of the content of geometry that they broached. Ana focussed on the composition of geometrical figures and the construction of symmetrical figures. Inês dealt with the classification, perimeter and area of polygons and the volume of cubes.

The treatment of some of this content would deserve more attention. For example, concerning the concept of the axis of symmetry (CO2) Ana mentioned that this axis divided the figure 'into two equal parts' without thinking about situations where axes divide a figure in equal parts and that there are also cases where the axes are not axes of symmetry. Although visual perception will be important work for the students for the identification of the properties of figures, it will be equally important to look at examples and counter examples of the content handled.

Inês - to cover the characteristics of some polygons (CO1) - tolerated these being designed on the blackboard and on worksheets but always in the same position. She gave the impression that she did not consider this attribute important for the identification of geometrical figures.

CURRICULAR KNOWLEDGE ABOUT GEOMETRY

Ana and Inês showed that they knew the current the mathematics syllabuses for the first cycle and its reformulation, since the time of their initial education during the period when the subject of geometry was played down. In relation to her time as a student, Ana stated that in the teaching "of geometry the subject was given rapidly and rather unattractively, because it would seem that it did not have as much importance as calculus" (PI2). Inês also did not have many memories of the subject of geometry and said that they gave the names of the "figures, areas, perimeter and volumes with the application of formulas; rarely in secondary school were these given, because they were at the end of the syllabus and the books" (PI2).

As far as the strategies used in the teaching of geometry were concerned, the teachers acknowledged that they focussed on what, "their professor would say and do" (PI2) and that the materials were not integrated into the class activities, as exemplified in the statement of Ana: "I do not recall that we used materials, there were only sums and calculations, it was a kind of repetition and memorisation" (PI2). When comparing such strategies of teaching with those that they developed in their classes, they showed knowledge about the methodological guidance of the current school syllabuses, as exemplified in the assertion of Ana: "we did experiments for understanding and not to commit to memory; they took offence if we wished to question things" (PI2).

In their observed classes an effort to articulate their personal representations and the new curricular directives was evident. A complex and slow process which aroused a conflict that was more evident in Inês than Ana. Inês considered that "I still have to get used to the new methods, as I have not learned this way" (PI2). So she was aware of this, because in the classes observed she did not instil discovery learning. For example, when working with the notion of the perimeter, she followed the method observed in the four classes that consisted of reading and explaining the definition, putting the question and immediately initiating the response that the students finished afterwards: "above all, according to the definition, we get that the perimeter of that polygon is equal to only… above write P is equal to …" (CO3).

Ana and Inês showed a preoccupation with adapting the development of geometrical content to new knowledge acquired in education, which they were developing. For Inês, this influence falls more upon the tasks that she proposes than on the process of the work with the students.

INSTRUCTIONAL KNOWLEDGE

The two teachers differed in the way that they organised their teaching of geometry. Ana conducted her practice of teaching with an approach that was open to the participation of and discussion among the students and, when convenient, used manipulative materials like "the *geoplan* and the *tangram* for creating geometric figures and exploring constructions; I make many displays, not I make, they make them, they cut out and compose displays" (PI2). This teacher values the use of individualised help for the clarification of difficulties that the students have, thus developing in them the "desire to ask things; I like them to learn and if a student has difficulties, I go near to them to help them" (PI2). Although she seeks to carry out her planning by - at times - directing the students towards the responses that she intends to obtain, she is preoccupies with the creation of moments for the carrying out of practical activities that involve the students. Therefore, she resorts to expressions of the type "let's start to make something" (CO1), "If you have any doubts we can examine them; let's see how much we manage to come up with" (CO4).

In spite of providing moments for the introduction of student-to-student activities with the objective of instigating discussion amongst the students, Ana does not always ask then to explain their processes. She turns to the use of different visual representations "in order to motivate them and for them to learn better; I think that their improvement in learning is what we are looking for, because I think that they think this is what I want them to do" (PI2). She also resorts to relevant daily representations of concepts by taking advantage of the use of manipulative materials. This teacher considers that the "concepts of geometry that do not allow work using different materials are difficult to teach to the students, as for example estimates" (PI2).

In her turn, Inês revealed herself to be a directive and expository teacher. Although attributing importance to the new methods of teaching, as opposed to the traditional way that so much displeased her as a student, she seems to have difficulty in overcoming these representations of the educational act in her classes. Her students have little opportunity for experimenting and explaining their processes, which would allow then to discover new knowledge. It is the same when she turns to manipulative materials like, for example, figures on paper, since this device does not perform its function of leading the students to discussions, making inferences and pointing out conclusions.

For Inês, the capacity of applying geometrical knowledge gets involved with "the carrying out of experiments and substantiations and recourse to materials to motivate the students" (PI2). But in her classes verbalisation predominates and the associated worksheet solution is in a very structured format: "for developing the content in the classroom, I almost always start with a challenge followed by more traditional problems for the students to see that the ideas that they learn adapt themselves to our day to day situations" (PI2). The procedures unleashed throughout the lessons were always the same: recourse to the blackboard to tackle the concepts related to the lesson content; reading and explanation of the definitions of the chosen concepts; executing the worksheets step by step with the student reading and a consequent clarification by the teacher.

In the communicational process Inês gave the students only one role, which was to respond to her questions, which were centred on her own discourse: she raised questions, steered the responses and left the students to complete phrases and to repeat or finish the reasons indicated by her. She even communicated the results by strongly hinting what the answers of the students should be without allowing them to make their own presentations.

CONCLUSION

It is generally considered that teachers are key elements in the educational process. However, it must not be forgotten that the teacher of mathematics also was a student, who developed throughout his school life knowledge about aspects of the didactical knowledge of mathematics. The manner in which he acquired this knowledge tends to have influenced the way how he interprets, understands and teaches, which is clearly perceptible in this study. In relation to geometry, the teachers revealed knowledge of the curriculum and a precarious knowledge about the content of this subject that is to be taught in the first cycle. In relation to curricular knowledge, Ana and Inês manifested knowledge about the content of geometry present in the syllabuses of all four years of the primary and of the learning objectives and didactic materials to be integrated into their strategies for teaching. This perception became explicit in the comparison between the methodological guidance in the syllabuses of their initial education and what the teachers currently accomplished. As for knowledge about the content of geometry, the teachers presented structured knowledge about definitions, formulas and calculations, which seemed to result from learning based on repetition and its uncritical assimilation. The knowledge of geometrical content seemed to fall well short of what is expected of a teacher, so that they can teach about it. As stated by Gomes and Ralha (2005), nobody can teach what they do know and it is not enough to have a superficial knowledge of elementary mathematics.

Ana and Inês showed knowledge about curricular guidance for the teaching of geometry and the importance of didactic materials in the processes of learning and activities developed by the students. However, their education tended to influence the knowledge that they had about the content of geometry and the way to teach it in the classroom. The experience that they acquired during their professional careers, as Inês mentioned, tended to "bridge some gaps in my education," (PI2) principally in relation to the representations that they used for making the content that they taught comprehensible.

In order to stimulate their teaching strategies, Inês valued teacher activity and the repetition of exercises, looked for the students to imitate what she did and valuing above all memorisation and the uncritical application of formulas. Ana valued the participation of the students by attending to their responses, resorting to drawings on the blackboard to indicate the significance of the selected content and using materials in order to favour discovery by the students. Yet, she did not always exhaust the responses of the students, when guiding them to what she intended should happen.

We concluded that the images that are developed during educational actions tend to condition the innovation of pedagogical practice. Knowledge of the methodological guidance in the school syllabuses and education that is developed does not always automatically guarantee the modification or transference of this knowledge into classroom practices. So as to overcome some obstacles in the teaching of mathematics, we consider that the teachers must involve themselves in the exploration of mathematical tasks by questioning and discussing ideas with other teachers in the same way that it is expected that they will do with their students. The present investigation is an example of work between peers in which the two teachers had an opportunity to reflect

about their own professional practice, which made them aware of the importance of reformulating their methodological options and being ready to put into practice their knowledge regarding the way to approach the content of geometry with their students.

Abstract: The purpose of this paper is to investigate teacher educators' motives for participating in faculty seminars and their perception of the contribution of these seminars to their personal to professional and social development. The research context was a monthly faculty seminar conducted in a college for teacher training in Israel. Data were obtained from 35 teacher educators using a questionnaire and from six teacher educators who were interviewed. Findings showed that teacher educators participated in the faculty seminars primarily because of their obligation as faculty members and because of their desire to become better teachers. Its main contribution was improving research skills and moderately contributed to the personal, professional and social domains. However, findings imply that well-implemented faculty seminars can meet the diverse needs of teacher educators and contribute to their development and consequently to the teachers they train.

Keywords: Teacher educators, professional development, faculty seminars

INTRODUCTION

Most teacher educators enter their job without participating in a preparation program for becoming teacher educators. Therefore, they have to develop their own professional competencies, particularly during the first few years of their work as teacher educators (Murray & Male, 2005). In addition, during their careers, teacher educators are exposed to many changes and reforms in teacher education which require them to evaluate and redefine their professional skills. Consequently, and in light of their multiple roles to instruct, teach, and provide support to student teacher (Koster, Brakeman's, Korthgagen, & Wubbels, 2005) attention to the professional development of teacher educators is imperative and may contribute to substantial improvement in the quality of teachers.

Professional development can be defined in various ways. In relation to teacher educators it was defined as the process by which an individual teacher educator improves the quality of his/ her work and tries to "become the best professional one can possibly be (Smith, 2003, p. 203)

Very little is known about the quality of teacher educators or their professional development. Teacher educators seem to be an under-researched occupational group (Ben-Peretz, Kleeman, Richenberg, & Shimoni, 2010). Much of the research on professional development of teacher educators is outdated, limited to specific professional activities, or constrained to descriptions of concrete courses for new teacher educators. An exception is an extensive study of 400 Dutch teacher educators which indicated that monitoring their own professional development is fundamental to their profession and is the most essential area to improve (Koster, Dengernik, Korthagen, & Lunenberg, 2008).

From this study and other few studies about the professional development of teacher educators one can learn that it refers to three main components (Dickman, 2005):

1.Personal components - professional Identity as "community membership" and as "learning trajectory" (Ben-Peretz et al., 2010, following Wenger's dimensions of identity, 1998)

2.Professional components – "teacher educators are firs of all teachers" (Tamir, 1998, p. 84). Accordingly, they are supposed to have the knowledge that is required from teachers and unique knowledge of teacher educators ("extras" according to Lunenberg, 2002). Tamir (1998) calls it unique pedagogical knowledge which contains four parts: communication, deliberation, analysis and synthesis and reflection. Reflective thinking constructs professional knowledge of practice (Koster & Dengerink, 2001); for teacher educators, reflection carries a dual purpose: reflect on their experience and develop their students' ability to reflect (Lunenberg & Korthagen, 2003). In addition, teacher educators must know how to explain their pedagogy to the teachers they are training (ibid) and have to conduct research (Cochran-Smith & Donnell, 2006; Tanner &Davies, 2009).

3. Social components - intra-personal intelligence - working with students and peers, being empathetic, assertive, committed and tactful (Smith, 2003), professional frame of reference – expert teacher educators associate themselves to the teacher educators group (Kupferberg & Ben-Peretz, 2004)

In conclusion it can be said that professional development of teacher educators is not limited to expanded theoretical knowledge in a specific subject matter, but it is more a whole person development with cognitive and affective aspects (Smith, 2003). The task for teacher educators is made even more demanding due to the fact that there is little, if any, formal preparation for their role; nor is there much in the way of ongoing professional support or mentoring (Lunenberg, 2002; Zeichner, 2005).

Routes in professional development of teacher educators

As indicated previously, there is little formal preparation for teacher educators' role. In addition, there is not much in the way of ongoing professional support or mentoring (Lunenberg, 2002; Zeichner, 2005; Berry, 2009). There are formal and less formal routes in professional development, some of which are for individuals and some involve the whole staff (Smith, 2003).

In Israel, teacher educators' professional development takes several forms: workshops and courses organized by the teacher education department as well as seminars organized by teacher education institutions. Smith (2003) classifies the routes in professional development of teacher educators in Israel to six forms: higher academic degree, in-service workshops and seminars outside the teacher education institution, staff development inside the teacher education institution, feedback on teaching, voluntary and forced support, and peer tutoring.

A literature review reveals that several aspects contributed to the success of formal programs for professional development of teacher educators: Giving attention to the integration of personal, professional and social development (Zaslavsky & Leikin, 2004); cooperative learning together with making reflection (Zaslavsky & Leikin, 1999); team work within the frame of professional community (Zaslavsky & Leikin, 1999; Dickman, 2005); making reflection (Zaslavsky, 2004); and the mentor of the teacher educators (Dickman, 2011).

The purpose of this study is to investigate teacher educators' motives for participating in faculty seminars and their perception of the contribution of these seminars to their instruction and their professional development. This study focused on a teacher educator seminar conducted in one teacher Education College; therefore it can be referred to as a case study.

THE RESEARCH CONTEXT

In Israel, teacher educators' professional development takes several forms: Workshops and courses organized by the teacher training board, teacher educators' seminars organized by each of the teacher training institutes. This study focused on a teacher educator seminar conducted within one teacher Education College. A monthly meeting was conducted by a member of the teacher educator staff or an external expert in a relevant domain. Participation in the seminar was mandatory, however, only part of the staff attended on regular basis.

The seminar meetings centered on various topics such as the place of curriculum in teacher education, promotion of high order thinking, reflective thinking, learner assessment and methods and strategies in learning and research.

METHOD

Participants

Data were collected from 35 teacher educators who participated in the faculty seminar at a teacher training college during the year 2010. Participants varied by gender (71% female), experience (45% at least 6 years), age ($\overline{X} = 49$), and academic degree (44% Ph.D., 56% Masters). Participant also varied by the area they teach. Six teacher educators who consistently participated in the seminar meetings were interviewed.

Research instruments

Data were obtained by means of a questionnaire administered to participants at the end of the seminar meetings. The questionnaire included questions related to: background and training, motives for participating in the seminar meetings, contribution of the seminar to personal and professional development and open-ended questions regarding, strengths, weakness of the seminar and suggestions for improvement. Motives for participating in the faculty seminar were measured by asking participants to rate the extent to which each of eight motives drive them to participate in the faculty seminar on a 5-point scale ranging from 1 (low degree) to 5 (high degree). These motives included importance of the seminar topics, obligation to the job, becoming a better teacher educator, receiving incentives, showing respect to colleagues, sense of belonging, fulfilling

requirement of the institute administration, and following a colleagues' recommendation. Internal consistency as measured by Cranach's α was .74.

Contribution of the faculty seminar to teacher educators was measured by 23 items intended to measure General and content pedagogical knowledge (8 items, Cranach's α =.94), Content knowledge (3 items, Cranach's α = .77), Application to classroom practice (6 items, Cranach's α = .92), and awareness of self /reflection (6 items, Cranach's α = .94). Items were grouped conceptually into dimensions because factor analysis unlikely to yield valid factor solution when sample size is small.

Qualitative data were obtained by means of three open-ended questions about strong and weak aspects of the faculty seminar, recommendation how to improve, and whether they apply ideas and methods presented, or emerged in the seminar meeting to classroom practices. Interviews were also conducted with six teacher educators to obtain in-depth data regarding issues emerged from the questionnaire data.

Procedure

The faculty seminar coordinator distributed the questionnaires to the participating teacher educators who filled them in their convenient time and sent them back to her. She then forwarded them on to the researchers.

The interviews were conducted face-to-face in a setting which was convenient for the interviewees. Interviews which lasted on the average about 45 were not taped, but rich notes were obtained.

FINDINGS

Findings related to both motives for participation in the faculty seminar and participants' perception of the contribution of the faculty seminar to their personal and professional development.

Motives for participation in the faculty seminar

Results reflecting the extent to which each of eight motives was responsible for participating in the faculty seminar are summarized in Table 1.

Table 1: Means and Standards Deviations of Participants Responses on the Motive for Participation Items Seminar

I participated in the seminar meetings because ----	*Mean*	*SD*	*Cronbach's α*
Motives	*3.86*	*0.63*	*.74*
1. The seminar topics were important	3.31	0.90	
2. I felt it is an obligations as a faculty member	4.14	0.81	
3. I wanted to become a better teacher	4.14	0.97	
4. It is important for me to receive incentives	2.79	1.41	
5. I wanted to show respect for my colleagues	3.74	1.07	
6. I wanted to feel I belong to the faculty	4.00	1.09	
7. My participation was important for the college	3.44	1.10	
8. Colleagues recommend participation	2.23	1.24	

(Scale 1-5; N=33-35)

As can be seen from Table 1, Teacher educators felt strongly that they should participate in the faculty seminar to fill an obligation as faculty members, to become better teachers and to feel they belong to the college team. The weakest motives for participation in the faculty seminar were receiving incentives and following colleagues' recommendations. However, responses related to these two motives were the most heterogeneous (SD= 1.41 and 1.24, respectively).

In the interviews with six participants they mention strengthening general knowledge, exposure to information in other areas and new information of one's area, filling an obligation to the institute and feeling affiliated with the college team, as motive for participating in the faculty seminar.

Contribution of the Faculty Seminar

How and to what extent does the faculty seminar contributed to teacher educators? Findings related to these questions are displayed in Table 2. On the average the contribution of faculty seminar was rated by teacher

educators, at best, only moderate in all domains, except improving their ability to conduct research which was rated relatively high.

Data from the interviews indicated that the faculty seminar contributed to participants in three major domains. The first domain is personal. Participants indicated they become aware of their teaching styles and were exposed to new interesting general knowledge which stimulates them to reflect on their knowledge, styles and values. In the professional domain, participants indicated that only part of the meetings contributed to their professional development, particularly those focused on topics which are relevant to their teaching. For example, one of the participants stated: "I learned how to handle student reflections". Other teacher educator stated that: "Participating in the faculty seminar reminded me of certain knowledge that encouraged me to read more and strength my desire to apply things in the classroom."

Table 2: Means, Standard Deviations, and Cronbach's α Coefficient for the Scores on the Contribution of the Seminar

Contribution of the faculty seminar	*Mean*	*SD*	*Cronbach's α*
General and content pedagogical knowledge	***3.04***	***0.83***	***.94***
1. My general pedagogical knowledge has been enhanced	3.34	0.87	
2. My knowledge about assessment has been extended	2.94	0.95	
3. My pedagogical content knowledge has been improved	2.86	1.00	
4. I feel expert in instruction	2.91	0.95	
5. My understanding of reflective thinking has been improved	3.23	1.00	
6. My knowledge regarding classroom teaching has been enriched	2.91	1.10	
7. My knowledge regarding learning processes has been improved	3.00	1.09	
8. I acquired instructional tools that promote student thinking	3.09	0.98	
Content knowledge	**3.12**	**0.88**	**.77**
1. My knowledge in various content areas has been enriched	3.24	1.12	
2. My knowledge in the content area I teach has been enriched	2.60	1.06	
3. My ability to conduct research has been improved	4.14	0.97	
Application to classroom practice	**2.96**	**0.88**	**.92**
1. I used ideas presented in the seminar and related to other content,	2.63	0.94	
2. I used ideas presented in the faculty seminar in my instruction	2.66	0.94	
3. I encourage my students to think reflectively	3.41	1.37	
4. I plan to apply methods and strategies I learned in my instruction	3.14	0.97	
5. I think that things I learned will be useful for my instruction	3.20	0.96	
6. My student learning has been benefited	2.70	1.02	
Awareness of self (consciousness)	**3.12**	**0.93**	**.94**
1. I become more aware of my teaching style	3.34	1.08	
2. I become more aware of my strengths	3.31	1.13	
3. I become more aware of my weaknesses	3.26	1.01	
4. I feel that I can become a better teacher educator	3.35	1.07	
5. I feel I has been developed personally	2.94	1.08	
6. I feel I has been developed professionally	3.03	1.15	

Items (Scale 1-5; N=33-35)

All Interviewees mentioned the contribution of the faculty seminar to the social domain. They indicated that seminar meetings provided an opportunity to know each other. For some participants, particularly new faculty, this social aspect is most important. As a female teacher educator said: "this [knowing each other] is what we need in this college." One interviewee took thing a step further by arguing that seminar meetings

provided opportunity to know about the specialty and the research domains of peer faculty which can encourage cooperative work and professional and personal growth.

The perceived applicability of topics presented in the seminar can be interpreted as perceived contribution. The quantitative data indicated that participants applied or intended to apply the seminar topics in their teaching to only a moderate extent. This pattern also emerged from the interviews data where participants pointed out that only part of the topics are applicable for their teaching such as using portfolio as an assessment tool, or classroom journals as learning and research tools.

General evaluation of the seminar meeting revealed strengths as well as weakness.

Interviewees described diversity of topics and seminar leaders, positive climate, relevance of some of the topics for many participants, and the high expertise of seminar leaders as strengths. Among the weaknesses they mentioned: Some topics were not relevant and some seminar leaders and participants took their work lightly (e.g., arrive late).

SUMMARY AND DISCUSSION

Teacher educators, in general are not trained or prepared for their complex job. Several routes are followed to fill this void and to help teacher educators to perform their job as effectively as possible. One of these routes is organizing institutional faculty seminars. Two unavoidable questions are relevant in this regard: what are the motives for participating in such seminars? And to what extent these faculty seminars contribute to teacher educators? These two questions were the focus of the present study.

Findings revealed that two primarily reasons derive participation in the faculty seminar: obligation as a faculty member and desire to become a better teacher. The first of these two motives reflect the desire to develop an identity as a teacher educator within an institutional identity. This finding agrees with arguments suggested by Wegner (1998) and reinforced by Ben-Pertez et al. (2010) regarding the personal components of professional development to which they refer as "community membership" and as "learning trajectories". The other motive relates to professional components as suggested by Tamir (1998) and later by Koster and Dengenrink (2001). The moderate rating that teacher educators gave to the other motives does not mean that they are irrelevant rather they might be less important than the first two. However, this finding should be interpreted with caution given that the information was self-reported, and that the importance of these motives might be context dependent.

The fact that teacher educators rated highest the contribution of faculty seminars to their research skills reflect the lack of training in this area and the need of providing in-service professional development in this area. This training should not be limited to faculty seminars and might be better served within different frameworks such as workshops and research forums. This aspect is important because engagement with research has resulted in positive changes to the knowledge, skills and critical awareness of the teacher-educators which has in turn brought benefits to the learning of their students (Tanner & Davies 2009). Along these lines Snoak and Klink argue:

> It would be very useful for teacher educators and researchers to engage in research aboutthe needs of beginning teacher educators, the way in which teacher educators prefer to learn and what expert teacher educators and heads of teacher education institutes consider they need to learn. (2009, p. 223).

Other personal, professional and social domains were benefitted to moderate extent as a result of participating in the faculty seminar. This implies that careful planning of these seminars can increase the relevance of their content and topics presented within them to the diverse needs of participants. Institutional faculty seminars have an advantage over other professional development activities conducted outside the institutional setting, because they can be designed to address the unique needs of the faculty team while taking into account unique institutional features, conditions and constraints.

In summary, since faculty seminars should be responsive to teacher educators needs, and given that much leeway is allowed in running them, they differ greatly with respect to composition, content, and operation. The result is great variation in participants' motives, perceived benefits and satisfaction. However, the findings imply that well-implemented faculty seminars can meet the diverse needs of teacher educators, provide them of opportunity to communicate, to create a learning cooperative culture and contribute to their personal and professional development. Clearly, further research is required in order to better understand the dynamics of faculty seminars and their possible benefits for teacher educators and their student teachers.

Abstract: The South African democratic government introduced change in all spheres of South African life. The challenges that they had to face in education was addressing the redundant, racialised curriculum, and the global focus from the poor results achieved by learners in 1995, 1999 and 2003 in The International Mathematics and Science Study. A key feature to these poor results was the large group of teachers who were inadequately 'trained' during the Apartheid era: trained to teach for subservience and not for critical thinking. Current actions to address this crisis are being undertaken in a collaborative relationship between the Department of Education and Higher Education Institutions. Current initiatives in the professional development of Mathematics, Science and Technology teachers at a South African university are explored. A driving question in this article is the exploration for a professional development programme that can effectively support the professional development of teachers in a developing context. The rationale, foundational principles, model of delivery, programme structure and assessment for the specializations of the teacher professional development programmes at the university are described. The discussion highlights the important role that the university plays in the professional development of teachers.

INTRODUCTION

In 1994, the South African democratic government under the leadership of the African National Congress (ANC) was sworn into power. Change was on the way – in all spheres of South African life. The apartheid laws and actions were abolished; all South African citizens irrespective of race, culture and creed had the right to vote and access to education. The discriminatory education system was renounced and new education policies were developed. Essentially, the democratic government was concerned with enabling all citizens to have "access to lifelong education and training" (Department of Education, 1994, p. 11). Thus, the education policies were concerned with increasing access to school and, also the quality and nature of schooling for all children eligible to attend. The policy of free basic education to all was a very attractive and acceptable policy for most South African citizens. Inherent in this policy was the expectation that all schools would have an acceptable quality of education.

The South African Department of Education, in their attempt to provide non-racialised, relevant, quality education for all introduced new school curricular. Since 1994, we have experienced three curriculum waves. First, in 1998 Outcomes Based Education (OBE) was introduced as a philosophy of education in schools and Curriculum 2005 (C2005) as the curriculum vehicle. Four years later, C2005 was reviewed and the Revised Curriculum was introduced. The National Curriculum Statements (NCS) was introduced in 2006 as the third curriculum. Each of these curricular brought expectations of what and how teaching and learning should take place for quality education to be achieved. The challenge that the Department of Education faced in improving the quality of education since 1994 was frustrated by the global focus on the poor results achieved by learners in The First, Second and Third International Mathematics and Science Studies in 1995, 1999 and 2003. The report of the 2003 TIMMS study showed that "South African teachers have extensive development opportunities, but the evidence of poor learner performance shows that these have limited impact" (Department of Education, 2006, p. 17). This limited impact can be ascribed to a large group of teachers who were inadequately trained during the Apartheid era: they were trained to teach for subservience and not for critical thinking. During the curriculum reform period many of these teachers attended basic education workshops to develop the required knowledge and skills for implementing the new curricular. But, these workshops proved to be insufficient for developing the teachers as competent implementers of the curriculum (Adler, Ball, Krainer, Lin & Novotina, 2005; Johnson, Hodges & Monk, 2010). What was required for the effective implementation of the new curriculum with were highly developed teachers who

could work with the intended expectations of the new curriculum, the necessary teaching and learning materials and a teaching and learning ethos that focused on achieving excellence and quality education (Adler, *et al.,* 2005).

The introduction of the NCS with its new subject areas and content features in many subjects made demands on teachers and learners. Learners in the Further Education and Training Phase (FET), which is Grades 10 – 12, were expected to either study Mathematics or Mathematical Literacy (ML), irrespective of the course that they would want to study at the tertiary level (post Grade 12). This policy change had implications of re-training and re-skilling teachers to teach a new subject - Mathematical Literacy. Natural Science and Technology teachers were expected to work with new content areas that they had not encountered even in their own professional development. These curriculum changes influenced Higher Education Institutions (HEIs) to design teacher professional development programmes to respond to the re-training and re-skilling of teachers. This was also a response to the growing demand for Continuing Professional Teacher Development (CPTD) in South Africa as outlined in the Report of the Ministerial Committee on Teacher Education entitled A National Framework for Teacher Education in South Africa (2005). Programmes for Mathematical Literacy, Natural Science and Technology Education were designed and implemented at an HEI (university). The driving question in this article is the exploration for a teacher professional development programme that can effectively support the professional development of teachers in a developing context.

DEVELOPING CONTEXT AND THE NEEDS (RATIONALE)

Since the introduction of the new government the Department of Education has been faced with numerous challenges. These comprise replacing the inadequate, racist school curriculum, disparity in the resourcing of schools in terms of the infra-structure, required teaching and learning materials, human resources, and the vast geographical spread of schools across urban and deep rural areas. In 2006 in South Africa, teachers were the largest single occupational group and profession in the country, numbering close to 390 000 in public and private schools (Department of Education, 2006, p. 5). These teachers were expected to play an important role in the development of the youth of South Africa, in preparing them for the 21st century and to be responsible, sustainable and economically active citizens who could contribute to the further development of the country.

The fact that "only 1 in 29 Black children entering the school system emerge with matric certificates (Hoffman, 2008, p. 2) which provide them with access to further their education and their training and employment in a poor economy, represents a classical example of an ineffective education. If we have the courage to recognise that many of our universities and schools across the political spectrum are "close to a point of breakdown" (Morrow, 2007, p. 184), then we have to also acknowledge that our education system is in "serious trouble" (*ibid*). As with the poor achievement of South African learners as revealed by international studies referred to earlier, national concerns identify "[P]oor quality teaching [as] the key reason why the education system is failing so many schools" (Paton, 2006, p. 1). Soudien's (2007, p. 188) statement reveals the counterpart (teaching) as the problem when he says that "the impact it [the country] is making on the *quality* of the learning experience of young children is questionable." Morrow (2007, p. 184) concludes by a "widespread conviction that we urgently need to improve the quality of teaching and learning in our schooling system". This is possible if professional development of all teachers is effectively planned and managed.

Teachers' work can be achieved if teachers are professionally developed to work with the expectations of a new curriculum and the changing contexts within which they work. One of the criticisms leveled against the failure of teachers to work with the curriculum - C2005 was the use of workshops to develop teachers, as opposed to using short courses or two years qualifications provided by HEIs (Chisholm, Volmink, Ndhlovu, Potenza, Mahomed, Muller, Lubisi, Vinjevold, Ngozi, Malan, & Mphahlele, 2000). The ACE programmes are developed taking this perspective into account. Whether the two year qualification is more effective as a teacher professional development model, still needs to be investigated. This is one of the research questions for the larger project that this article is linked to: How effective is the formal ACE inservice qualification as a professional development model in the province of KwaZulu-Natal?

During these professional development programmes teachers need to be developed to have the necessary knowledge competence of the subject that they teach and to interpret and utilize teaching resources and learner support materials effectively (Department of Education, 2010). Teachers of Natural Science and Technology are expected to have the new knowledge and skills that are included in the curriculum for the Natural Sciences and Technology Learning Areas (subjects). The expectation for the Mathematical Literacy field (subject) was for teachers to be trained to teach this subject as this was a new subject in the curriculum.

The challenge therefore for the South African Department of Education was to establish initiatives for the professional development of teachers to teach these subjects. The initiative undertaken was a collaborative relationship between the Department of Education and HEIs. The HEIs were expected to design and implement Advanced Certificate in Education (ACE) programmes to meet the need for professional development of teachers who are currently teaching but do not have the necessary competences to work with the curriculum. Professional development therefore was viewed as the solution to various educational reforms made by governments yet there is a dearth of research on the effectiveness of formal qualifications such as the ACE Mathematical Literacy, Natural Science and Technology Education. Furthermore there is a lack of research on the effect of spreading these across multiple learning sites (Adler *et al*., 2005). Adler, Pournara, Taylor, Thorne and Moletsane (2009) further add that impacts on teaching and learning should consider examining the practices of teacher education with respect to "breadth and depth of domain knowledge; subject content and pedagogy" (p.39).

In this article we focus on the meaning of professional development in a developing context and a descriptive analysis of the ACE programmes - Mathematical Literacy, Natural Sciences and Technology Education.

PROFESSIONAL DEVELOPMENT OF TEACHERS THROUGH ADVANCED CERTIFICATE OF EDUCATION PROGRAMMES

This section of the article addresses the meaning of teachers as professionals in the South African context. It raises issues on professional development in a developing context and the implications of these for the design and implementation of a teacher professional development programme.

Teachers as professionals

In describing teachers as professionals in the South African context we could refer to the roles as laid down in policy or descriptors used by teacher education researchers. The Norms and Standards for Educators policy document (2000) requires of a teacher to be a specialist in: a particular learning area, subject or phase, teaching and learning, assessment, curriculum development, a leader, administrator and manager, a scholar and lifelong learner and a professional who plays a community, citizenship, and pastoral role (Department of Education, 2006). The meaning that theorists ascribe to professional teacher is politically, socially and culturally influenced. In Morrow's (2007b) terms, for example, a profession has two characteristics: "theoretical nature of professional practice and the ethical dimensions of a profession" (p. 78). Within the South African context, this meaning cuts to the core of the characteristics that professional teachers should possess as many lack appropriate content knowledge, pedagogic content knowledge and an effective work ethic. Researchers essentially agree that the teacher as a professional should possess "competence in and be committed to the practice of professional teaching" (Morrow, 2007b, p. 75); make decisions about teaching and learning for particular learning environments with "confidence and commitment" to teach learners (Samuel, 2008, p. 15) and have the qualities of flexibility, courage, thoughtfulness, resilience, independence and self-reliance (James, 2009).

Teachers may be regarded as members of a profession (Morrow, 2007b) whose 'actions' and work are shaped by many different demands made on their work in general (Samuel, 2008; Morrow, 2007b; James, 2000) and the internal and external challenges for quality learning (Hoffman, 2008; Soudien, 2007; Morrow, 2007b). It is for this reason that a critical descriptive analysis of the ACE programmes is presented. Teacher professional development does not occur in a vacuum and they are expected to learn and develop on a part-time basis, while still working, running families and being confronted by various challenges in their communities e.g. poverty, AIDS sufferers and grieving learners. The particular models, methods and pedagogic content knowledge used by HEIs to re-skill and re-train teachers needs to take these aspects into account.

Professional development of teachers in a developing context

A foundational principle of this study is that professional development within a developing context is different to professional development in a developed context. Thus in this study we hope to make recommendations about the form and substance of formal qualifications that work with teachers from the diverse contexts – deep rural to urban, in the province of KwaZulu-Natal. Many of these teachers have to consider issues such as safety of schools, poverty of the learners, poor school and district support, insufficient community involvement, nonexistent curriculum support. Teachers also have to contend with curriculum issues where they "tend to be driven to such frenzy about 'assessment' and 'portfolios' that they have little time to teach" (Morrow, 2007a, p. 8).

In the climate of curriculum change, all teachers were expected to enhance their skills, not necessarily their qualifications. Johnson, Hodges and Monk (2010) are of the view that knowledge is necessary for a change in teacher practice but it also requires a teacher's willingness to change (James, 2000). A large majority of teachers "need to strengthen their subject knowledge base, pedagogical content knowledge and teaching skills" (Department of Education, 2006, p. 16). The provision of a professional development programme and teacher's participation in it thou, does not guarantee change in teacher's teaching practice. For the majority of South African teachers the enhancement of skills and qualifications was necessary as stated earlier, as they did not receive adequate training for the teacher profession under the apartheid system. According to Lieberman and Mace (2008, p. 226) a natural solution then was to "teach teachers how to improve their practice". But, this was a complex issue interwoven with the political, educational, personal and institutional demands and would limit the teachers further (Morrow, 2007 a). Many teachers viewed the professional development workshops provided by the Department of Education as "fragmented, disconnected, and irrelevant to the real problems of classroom practice" (*ibid*).

Foundational principles for Professional development programmes
Morrow (2007 a) challenges us to think about two important questions when designing and implementing teacher professional development programmes: what work is expected of teachers and what are the contexts in which they work? Teaching occurs in a sociocultural context (Van Huizen, van Oers & Wubbels, 2005; Hughes, 2006; Morrow, 2007b; Samuel, 2008, James, 2009) where it "concentrates on the connections between individual functioning and development *and* the sociocultural practices in which individuals take part" (Van Huizen *et al.*, 2005, p. 271). Each teacher's learning and development cannot be understood if it is viewed as removed from the everyday actions e.g. thinking, facilitating learning actions that they participate in. Within this theory the teacher and his/her environment (society) are viewed as "a unified system in which these two elements are joined together in a dialectical relationship" (*ibid*). Morrow (2007 a) spells this out further in that a teacher programme should "develop an understanding of both the formal and the material elements of teaching" (p. 27). Research conducted on the development of teachers' understanding in a Natural Science ACE programme concluded that an:

> effort should be made to address students' [teachers'] views of how they learn and acquire knowledge, especially in the light of the fact that most of the students who enroll for ACE courses are mature adults whose epistemological beliefs about knowledge and learning are firmly entrenched (James, Stears & Good, in press, p. 11).

In the Faculty of Education the ACE programmes are designed to reflect "the necessary and enabling features for an ACE to achieve its purpose. The curriculum is suited to its purpose, internally coherent, and mindful of the needs of the students (Faculty of Education report, 2006, p. 19).

The programmes
The programme structure is one in which there are eight modules consisting of six discipline-specific modules and two generic modules. Four of the six modules are devoted to the development of content knowledge skills. The two modules are devoted to the development of pedagogic content knowledge skills. The two generic modules focus on general professional development, on students developing an understanding of policy, conditions of service and the roles of the educator (teacher). ACE programmes follow a 25-25-50 split between educational studies; pedagogic content knowledge and content knowledge. An example of the programme is seen from the Mathematical literacy in table 1 below:

Table 1: Modules in the Mathematical literacy programme

Content Modules	• Curriculum Studies in Mathematics 1A	16 credits
		16 credits
	• Curriculum Studies in Mathematics 1B	16 credits
		16 credits
	• Curriculum Studies in Mathematics 2A	
	• Curriculum Studies in Mathematics 2B	
Pedagogic Content Knowledge Modules	• Mathematics Education 1A	16 credits
		16 credits
	• Mathematics Education 1B	
Generic Modules	• Education Policy and Professionalism	16 credits
		16 credits
	• Teaching and Learning	
		128 credits

The generic modules are designed in such a way that teachers become more informed about issues relating to the profession whilst at the same time their development of professional ethics is also examined. In this module issues such as rape and others related to safety of learners and learner conduct is addressed. Teachers are also provided access to more general pedagogic knowledge relevant for teachers within the new South African context, through the module "Teaching and Learning".

This programme design is driven by the belief that teachers should not only be competent in their own specialist area, which is Mathematics in this instance, but they need to have a wider knowledge base as they are part of the members of the school and the community at large. For example, one of the modules in mathematics education deals with the psychology of learning mathematics, hence, the generic discussions from the core module are extended to provide a context and setting within the field of mathematics and/or mathematics education.

The programmes undergo quality assurance by a quality assurance committee whose primary terms of reference are to review the quality of the work and monitor procedures that can improve the quality of teaching and learning (Faculty report, 2006).

The participants

The ACE programme considers the selection of teachers as critical hence, a teacher, who enrolls for an ACE programme, needs to have a Matric plus three years of training (M +3). Teachers who do not have the M +3 are advised to complete an upgrading qualification first before they can be accepted. Completion of the ACE 2- year part-time qualification renders an underqualified teacher (with three years of teacher training post matric) qualified. These teachers come from rural and urban settings (contexts).

Model of delivery

Timetable design provides for two years of part-time study and enables a coherent development of the programme's specialised focus. The mode of delivery is block teaching during school holidays with some Saturday contact periods in between, and where necessary. Each content and mathematics education module is allocated at least 52 ½ hours of contact time, whilst each of the core modules is allocated at least 30 hours over block periods during school holidays in January and July each year, excluding examinations and tests. Because the contact sessions all take place during school holidays and/or Saturdays, this enables practicing full-time teachers to participate in the programme and does not undermine their school responsibilities. This mode works particularly well with our student population and ensures that students from rural and outlying areas are not disadvantaged. The teaching of the module takes place at different learning sites close to the place of work and residence of the teachers. These learning sites are structured, designated university teaching sites called learning centres.

Each module has an introductory contact session at the time of registration during which handouts, worksheets, secondary reading lists (to encourage students to start using the library) and/or notes are given to students and the aims of the modules are discussed. Expectations of students and lecturers for the duration of the module, which are also clearly listed in the materials, are discussed. This is then immediately followed

by the block and/or Saturday contact sessions. Teaching and learning methods and the mode of delivery support the developments of applied competences with lecturers and tutors always ensuring that they themselves in their own teaching model classroom teaching methodologies.

The modules are materials based, interactive, and user friendly, taking into account English second language learners. The delivery involves self-directed individual study, contact sessions, group discussions and peer learning, and, tutorials in which individual learner-tutor contact is promoted. Over and beyond this, students who need additional support are encouraged to call tutors/lecturers or make individual appointments where their specific needs can be addressed. Practicing teachers, many of whom travel long distances to get to the centre, where contact sessions are held and therefore relevant forms of support for such students are part of the programme design. The design of the programme and its mode of delivery enable development to take place over the semester through pacing the learning and feedback between the contact sessions.

Assessment

Assessment policies, procedures and practices are in place for each module in the ACE programmes. Module templates explicitly state what the assessment strategy is as well as the assessment criteria used to achieve the exit level outcomes. Different modules do have different assessment practices and assessment is continuous throughout all modules with both formative and summative assessment implemented. A variety of assessment methods such as tasks, presentations, assignments and tests are implemented in an attempt to address the variety of learning styles of students. The focus of the assessments is the teachers' personal subject specialization development (knowledge and skills within the specialization itself). In some modules there are ongoing tasks focused on developing understanding related to the teaching and learning of specialization topics relevant to the school phase (grade level), developing and using resources for teaching the specialisation at this level, and analysing and reflecting on learners work (learner productions, errors and misconceptions).

A calendar is developed by the Academic Qualification Coordinator for all ACEs at the beginning of the year and is aimed at assisting staff to plan their teaching and learning activities, assignments, and setting of examinations. The calendar stipulates deadlines for activities such as class mark and DP generation, informing students whether they qualify for the exam, among other things. Take away assignments have to be submitted by specified dates. If students submit assignments by hand then they can only be handed to the ACE Administrator who records the date of submission and the student signs a register, otherwise in most instances, students are required to register posted assignments after they have made a copy in case the assignment is 'misplaced' in the postal system. Students may be penalised for late submissions. No assignments are accepted once marked assignments have been returned to students. Students receive feedback regarding their assignments and are therefore always in a position to profit from academic feedback.

Tests are written during contact sessions and feedback occurs at the following contact session, or posted to the students. Students are thus continuously aware of their progress and performance on the course. All marked assignments and other work done by students has to be returned to them at least two weeks before the final semester examination. Assessment results are also used to respond proactively to student difficulties as they become visible. In general, Module Co-ordinators are responsible for monitoring and providing feedback within each module, and Programme Co-ordinators are responsible for monitoring student progress across programmes. Regular meetings of the ACE Qualification Committee provide the forum where concerns about student performance and progress, amongst other things, can be addressed.

There is also an end of semester examination for each module, which could take the form of a sit down examination or the submission of a portfolio of work. The mix, balance, assessment criteria and weighting of assessment activities are thus consonant with the exit level outcomes and selected aspects of the roles specified in the Norms and Standards for Educators and National Framework for Teacher Education. All procedures for assessments are made explicit to staff and students through the Faculty Handbook and/or ACE Handbook.

DISCUSSION AND CONCLUSION

The ACE programmes are structured and focus on the teacher professional development. The structure is evident in the entrance requirements, the programme design and implementation, the delivery mode and assessment, all of which take the teacher's needs into account. Developing teachers for quality education does entail that the HEI considers this as a crucial step in its own mission and community engagement endeavour. As a Faculty of Education its priority is concerned with quality education and supporting the claim that teachers are the essential drivers of a good quality education system (Department of Education,

2006). But, this professional development of the drivers cannot be divorced from the contexts that they experience in South African schools from urban to rural settings. The nature and extent of the experiences vary across the settings but one thing that we are sure of it that teacher's work is not just to teach. We, therefore recognize the important role that the HEIs play in designing and implementing ACE programmes that are conceptually, socially and personally based, in the South African context.

The teachers registering for the ACE programmes, right from the outset are taking their professional development into their 'own hands'. This initial step is important in the South African context where teachers have been teaching for years and have not bothered to participate in professional development programmes unless forced to do so by the Department of Education for new curriculum engagement. Even though the Department of Education has a policy that states, "it is the responsibility of teachers themselves … to take charge of their self-development by identifying the areas in which they wish to grow professionally, and to use all opportunities made available to them for this" (Department of Education, 2006, p. 27), many teachers do not do this. Research conducted on ACE teachers indicated that "some [teachers] have been teaching Science for more than 10 years, and have never before attempted to improve their scientific knowledge." (James *et al*., in press). This is tragic, not just for the teachers but for quality learning for learners. This professional ethic or lack thereof, cannot be allowed to permeate the education system especially when teachers say that they cope by either avoiding to teach a section [of work] or by asking another teacher to teach it (James *et al*., in press, p. 10).

397 - Student Research and Service-Learning for Community Enhancement: Case studies

Angela James

University of KwaZulu-Natal
jamesa1@ukzn.ac.za

Abstract: Twenty one Biological Sciences student teachers participated in a Research and Service-Learning module at a Faculty of Education. The focus of the module was on students' developing and conducting research on their Service-Learning in an Old Age Home and Children's homes. Their Service–Learning was concerned with the enhancement of the aged and the young children according to identified needs. The theoretical framework used focused on the real aspect of learning and it provides specifics about the nature of the problem. Authentic learning requires real life problems; active learners, the achievement of an outcome and experiential learning in a real context. The enhancement of the community is in collaborative, participatory actions, where knowledge and skills are shared for them to gain control of their lives. A qualitative, interpretivist, case study research design was used to explore the student's action. Data collection methods included student reflective diaries, student research reports and researcher observation notes. The data revealed that students' and the community were engaged in the community enhancement action, in responding to the needs of the community. Most importantly the Aged, and the young children were engaged with the student teachers in using their collective knowledge and actions to enhance their lifestyles. The Aged expressed how and in what ways they were developed where they were taught exercises and creative activities to reduce the effect of frailty and Osteo-arthritis. The young children took action in making and sustaining food gardens, and adopting healthy actions in their lives for sustainable living practices.

INTRODUCTION

Education in South Africa has undergone extensive changes. These are evident in the different curricular that have been implemented, reviewed and reformulated, the role of education personnel, learners, parents and the community in providing quality education for all citizens. Education and the role of teachers and learners in making positive impacts on the social and economic development of communities is gaining a strong foundation. This expectation is laid out in the learning outcomes of the current school curriculum – National Curriculum Statements (NCS) and Norms and Standard Teacher Education Policy document (2000). An outcome is for learners and student teachers to be able to "use science and technology effectively and critically showing responsibility towards the environment and the health of others" (Department of Education 2003, p. 2). Teacher education policy focuses on the role of the teacher in engaging learners in community development of their communities.

For any country to survive into the 21st cenutary, development strategies that are integrated into the education system are necessary. South Africa currently experiences high unemployment rates, negative impacts of HIV/AIDS, child-headed families and a growing population of aged and youth who lack financial security and live in unhealthy conditions (Department of Environmental Affairs 2007). Development strategies, therefore would be concerned with teachers, learners and communitiy members taking responsibility and undertaking actions to make a difference for all. This is not an instantaneous process as it involves the integration of social, economic and biophysical aspects of the environment into the curriculum of learners at schools and the professiona development of student teachers during teacher education programmes.

The hardships experienced by some South African citizens are lessened by non-governmental organisations (NGO) that have taken on the resposibility to give every citizen a fighting chance. Some NGOs work in collaboration with education institutions where student teachers are exposed to the challenges and the worlkings of the NGOs. Also, student teachers are empowered to achieve knowledge and skills, an awareness of and actions to be conducted for self and community development and empowerment. Some Higher Education institutions engage student teachers in programmes where they could be moved beyond developing awareness about people's impact on the environment and the so called green and brown issues of the environment but to community development and empowerment.

Student teachers should be professionally developed to implement Service-Learning when they are teaching learners in the schools. But, they would only develop the true value and skill of how to do this if they experienced it within their own teacher professional development. It is for this reason that in the Faculty of Education a Biological Sciences for Education module, which has Service-Learning as its focus was designed and implemented. In this module student teachers are expected to develop as novice researchers and Service-Learners. This development should be in the frame of Service-Learning where student teachers develop the theory about Service-Learning at the university and support the community based NGOs in working with identified needs. The student teachers then conduct research on their engagement with these community based NGOs. The importance of this engagment was for the student teachers to develop a "sense of social responsibility and commitment to the greater good" (Howard 1998, pp. 23-24).

The purpose of this research was to explore the student teachers' enhancement actions that they carriesd out in selected community based NGOs - an old age home and two children's homes (Drop In-centres) and the impact of these on the communities.

LITERATURE REVIEW

In this section I present literature on Service–Learning and its role in teacher professional development and community develpment in South Africa.

In South Africa, many teachers are expected to deal with issues of gender related violence, HIV/AIDS, poverty and crime that the learners bring to school (Bhana, Morrell, Epstein and Moletsane, 2006). It thus seems inevitable that student teacher professional development should encapsulate the complexity of educating learners in the highest possible quality education practice with regard to empowering community based NGOs through Service-Learning.

Service-Learning has been defined by various authors:some have focused on the service component, others on the learning component and others on an equal focus on service and learning. Service-Learning was defined by Sigmon (1979) as an experiential education. Furco (1996) highlights the use of the term Service-Learning by different organisations, "to characterize a wide array of experiential education endeavours, from volunteer and community service projects to field studies and internship programs" (p. 1). He views Service-Learning as seen in Service-Learning programmes, as "distinguished from other approaches to experiential education by their intention to equally benefit the provider and the recipient of the service as well as to ensure equal focus on both the service provided and the learning that is occurring". He further states that, "service learning programmes must be designed in such a way that ensures that both the service enhances the learning and the learning enhances the service".

In this article the meaning of Service-Learning used embraces both service and learning in a transformative manner, where student teachers are expected to be empowered to address community needs, and in the process empower community members. This meaning of Service-Learning is evident in the following: students develop a lifelong commitment to service and leadership and Service-Learning "promotes understanding of local issues as well as recognition of the interrelatedness of communities and societies across the world" (International Partnership for Service-Learning and Leadership 2007, p. 1). The focus of Service-Learning is such that student teachers and the community are expected to "equally benefit … [and there is an] equal focus on both the service being provided and the learning" (Furco 1996, p. 1) on the part of the students. The focus in this research though is on the actions that the students and the community conducted for the benefit of the community.

Research on student teacher professional development focuses on engaging student teachers in Service-Learning and researching this engagement. Dé Bryant (1996) is of the view that we need to move beyond exploring the meaning of research, to include community action/activities that are directly related to one's academic expertise. According to Eyler, Giles and Braxton (1997), when students are engaged in Service-Learning they have a positive development in their attitudes, values and a better understanding of social issues.van Niekerk (2007) conducted research on student teachers engaging in Service-Learning in Adult basic education. He concluded that Service-Learning "enriches a student's total learning experience at a tertiary institution and provides opportunities for better closer public relations" (van Niekerk, 2007, p. 18). The students in van Niekerk's research expressed their enjoyment of Service-Learning in that they took individual responsibility, their learning was practical, they shared ideas with many people, learning from others and the challenges that they experienced. These students also expressed the most significant things that they had learnt and what they came to realize. The students as a result of the Service-Learning realised "the importance of patience, challenging pre-conceived ideas, to be reliable and not to take simple tasks for granted and that every body is a person" (van Niekerk, 2007, p. 16).

The theoretical frameworks that underpins this research is authentic learning and community empowerment. Learning may be viewed as a change in a person's understanding and in his/her relationship to the world (Lombardi, 2007). It is also viewed as an active, social and sensory process that occurs effectively in authentic contexts (Van Huizen, Van Oers & Wubbels, 2005). Learning also has an active component in that it is "learning by doing [action] that is the most effective way to learn" Lombardi (2007, p. 2). It is in learning, that learners increase their capacity to act effectively in the world (Senge, 1990; Lombardi, 2007). Lombardi's (2007, p. 2) view of authentic learning captures the real aspect of learning and it provides specifics about the nature of the problem and the strategies which are used for effective learning to occur. Authentic learning therefore requires real life problems; active learners, the achievement of an outcome and experiential learning in a real context.

Empowerment is a construct that is used in the field of psychology, community development, economics, education and social science and its meaning varies among these fields. Attributing a single definition to it may make attempts to achieve it formulaic or prescriptive-like and this would contradict the concept of empowerment (Page & Czuba, 1999). According to Bailey (1992 in Page & Czuba, 1999) how we define empowerment within projects will depend on the people and the context. Theorists view empowerment as a construct that links individual strengths and competencies, natural helping systems and proactive behaviours to social and political change (Rappaport, 1984; Perkins & Zimmerman, 1995). Empowerment, generally defined is viewed as a "multi-dimensional social process that helps people to gain control over their own lives" (Page & Czuba, 1999, p. 2). According to Page and Czuba (1999, p. 2) empowerment occurs at various levels, "individual, group and community." In viewing empowerment, issues of wellness versus illness, competence versus deficits and strength versus weaknesses (Perkins & Zimmerman, 1995) are explored. Perkins and Zimmerman (1995) are of the opinion that "empowerment-oriented intervention enhance wellness while they also aim to ameliorate problems, provide opportunities for participation to develop knowledge and skills and engage professionals as collaborators instead of authoritative experts" (p. 570). In this research the view of individual and group empowerment was used where it focuses on the enhancement of the community in collaborative, participatory actions, where knowledge and skills are shared for them to gain control of their lives.

METHODOLOGY
Sampling
Twenty one final year Biological Sciences student teachers completed the module in 2010. This article reports on the community enhancement actions that four student groups engaged in. The selection criteria used were decided by the placement sites of an old age home and a children's Drop In-Centre. Four student projects were selected: two projects that focused on the aged and two that focused on the children. The projects on the aged focused on (1) teaching them exercises to reduce Osteo-arthritis and (2) creative activities to reduce the effect of frailty. Projects on the children focused on the development of young children to (1) take action in making and sustaining food gardens and (2) adopting healthy actions in their lives for sustainable living practices.

Context
The student teachers' research and Service-Learning environments and their activities were completely removed and different to that which they had encountered when teaching learners at schools. The student teachers were based in a township. The project with the aged was at an Old Age Home in a township, Clairville and the project with the children was at a Drop In-Centre in a township, Dengezi, Both townships are within a 20 kilometre radius from the university. The townships were developed during the Apartheid period where many Black people were not permitted to live in the towns. They were forced to live in areas close to the cities but these areas lacked services etc. Both townships are in semi-rural areas with a number of one-and two-bedroomed block houses, informal structurescows and goats grazing, land and 'container shops'. Both areas had extensive levels of poverty and unemployment.

The Old Age Home was started over thirty years ago by professional Black women who were concerned about the state of the aged in the township. It is an NGO and relies on funding from various sources for its existence. There are over in one hundred aged at ages ranging from 55 – 86. The aged at at different levels of health and they are accommodated accordingly.

The Drop In-Centre (DIC) is a two roomed house built in a residents backyard. This centre is supported financially, educationally and socially by an outreach centre at a local hospital. Food and educational material is given to a housemother who is responsible for the management of the centre. This centre runs from seven o clock in the morning until four o clock in the afternoon. Children who have been identified by

the outreach centre as destitute and needing support to live attend the DIC. Schoolgoing children have breakfast and go to school to return to the DIC for lunch and homework support. The younger children are fed at the DIC and they participate in school readiness programmes that the housemother and a helper teach. At the end of the day all the chilldren go to their respective places where they stay.

Research design
A qualitative, case study design was used. This qualitative approach was selected as the purpose of the research was to explore the enhancement of the community. This purpose is supported by Creswell (2003, 181) who states that "qualitative research is concerned with interactive and humanistic" aspects. The case study was used as it focused on "just one instance of the thing that is to be investigated… [and the case] is something that already exists, it is not artificially generated." (Denscombe, 2003, p. 31).

Qualitative data is viewed as by researchers as significant and the data collection involves "documenting real events, recording what people say, observing specific behaviours, studying written documents" (Neuman 1997, p. 329). It is for this reason that the student teachers were expected to record their experiences in a journal. Since engaging the student teachers in community enhancement projects is "education that is grounded in experience" (Jacoby & Associates 1996, p. 9) the student teachers were expected to reflect on the process of this enhancement. Ethical aspects and research validity procedures were followed in this research.

The case studies are descriptive accounts of the student teacher group projects with the aged and the youth. These case studies were extrapolated from the student teacher reflective diaries, student research reports and researcher observation notes. The data was electronically recorded. All the data for the four student teacher groups was read. The data was analysed using an inductive approach (Cohen, Manion & Morrison, 2007), which focused on the actions of the students and the community for enhancement. It was then placed into categories which were previously decided by the researcher. The categories that emerged from the data were: collaborative, participatory actions, and development of knowledge and skills.

FINDINGS AND DISCUSSION
The findings are presented as case studies for the projects with the aged and the youth. The project on the aged focused on the student teachers teaching them exercises to reduce Osteo-arthritis and creative activities to reduce the effect of frailty. The projects on the children focused on the development of children to take action in making and sustaining food gardens, and adopting healthy actions in their lives for sustainable living practices.

Student teachers and empowerment with the aged
Four student teachers met with the managers of the Old Age home to identify their needs. The managers described the range of conditions that the aged experienced and they were interested in how the student teachers could make a difference with the aged. The student teachers met to discuss the conditions that the aged experienced, to decide on what they could work with. Two student teachers decided to work with the aged who had Osteo-arthritis since one student teacher's granny, who had passed on, had it and the student teacher was aware of the pain and suffering that her granny had experienced. The other two students decided to work with the frail women as they were interested in this.

In each case the student teachers did not have the depth of knowledge and skills to work with the aged who displayed the named conditions. They decided to inform themselves by contacting specialists in the field and accessing resources. They engaged themselves in self-learning activities for them to be competent to work with the conditions that the aged had. The student teachers had initial introductory discussions during the first two weeks of the project with the aged.

Exercises to reduce Osteo-arthritis
During the introductory discussions the aged shared their biographic details, history, knowledge of causal aspects, current experiences and treatment for their condition. The student teachers shared their details of the project in that they were "interested in working with the aged who has Osteo-arthritis" (Thobe, September, 2010) and they discussed the reasons for their interest. During this discussion it became evident that three aged people thought that using cold water caused it, while two did not have any idea of its cause. All the aged indicated that they were receiving medical treatment for their condition and this "relieved the pain a bit in the joints" (Aged, September, 2010). The aged expressed the view that they had limited knowledge about their condition and when the students asked if they wanted to know more about it, they agreed. The student

teachers developed a Powerpoint with large visuals (some Aged were illiterate) to present to the aged on the meaning, causes and actions for alleviating the condition. A student teacher, Thobe reflected that:

> "In our presentation there was a part displaying old people exercising, trying to deal with the pains on the joints. They were so motivated in such a way that they asked us to bring the pictures of different exercises that they can do on their own when we are not there" (Thobe, October, 2011).

The student teachers and the Aged decided that an exercise programme would be the action to take. The student teachers shared that this was recommended by Oseo-arthritis researchers as the best mechanism to reduce pain and all forms of disability associated with it.

The student teachers planned an exercise progamme for the Aged. They discussed this exercise programme with the managers of the centre and a specialist trainer, who approved it. As, none of the Aged had done any exercises in the past, they were eager to engage in it for a period of five weeks (the duration of the student project). The programme was based on the exercise principles of overloading, progression, specification and reversibility and it was personalised for each person, e.g. the type of muscle group to be trained. The student teachers also made exercise instruments that were comfortable for the Aged to use. The Aged undertook these exercie activities three times a week for two sessions of thirty minutes each for a period of five weeks. The student teachers held weekly discussions with them on their experiences with the exercise programme. Precautions for exercising were discussed "excessive exercise may lead to muscle soreness and increased pains" (Michiela, September, 2010).

At the end of five weeks the student teachers and the Aged held a post-exercise programme discussion. The Aged shared the impact of this exercise on them. They stated that generally they felt much better, "pains are no longer severe", "I even sleep a bit better at night", I can walk a bit without my walking stick", "sometimes I did more exercises than what I was supposed to do and I got muscle cramps. I will have to stick to the programme." The Aged were more informed about their condition and they could take charge of it by exercising and reducing the negative impacts of it. The student teacher Michaela reflected that "participants, (Aged) are so happy with our Service-Learning ...the Aged to work freely without feeling stiffness on their legs and arms".

Creative activities to reduce the effect of frailty

Two female students interacted with three women who were identified as frail by the NGO managers. An introductory session was carried out where student teachers discussed their intention for the interaction with the women. Nomu reflected that,

> "we walked around introducing ourselves to our target group stating our name, why we were there and getting to know them. We sat with them for the whole three hours while they told us stories of them growing up and how they behaved when they were young. It was an amazing experience" (Nomu, September, 2010).

The student teachers explored the things that the women could not do due to their condition. The women varied in their ability to bath themselves, gripping with one or both hands, walking with support, toilet useage and doing their own laundry.

As the women needed to strengthen their small muscle movements, the student teachers discussed possible creative activities that could improve these movements. The activites were painting and beading. When the student teachers shared the creative activities with the women, they were reluctant to paint as they had never painted before. The student teachers decided that they would also participate in the activity to encourage the women to paint. The students stated that one of the women was reminiscing about her childhood when she drew pictures with charcoal. While the women painted they also exercised their feet, and their hands. One woman drew a house with a guava tree and a bench as this is what her house looked like. The women were also exposed to a beading activity. Before they started the activity they had to do hand exercises. The women found the beading activity a bit challenging because they had to thread beads onto a thread of twine/cotton and also make designs with them. They made bracelets and necklaces. After a period of five weeks of exercising, drawing and beading with the women, the student teachers expressed the emotion that the women had experienced during the time. During the last session, "this activity was long and during the making of bead-necklaces we asked them how they felt and they were excited and looked back to the days when they were younger". The outcome of these activites was that there was a slight improvement in the use of the womens' hands for gripping objects.

Student teachers and empowerment with the youth
Three student teachers met with the housemother and the manger of the NGO to establish the needs of the organization. Since the organization worked with children at Drop In-Centres, the students visited the site to meet the children and observe the context of the centre. From the discussion and the observation the students in conjunction with the centre personnel identified the needs. These were educating the children about knowledge and skills in making and sustaining food gardens, and adopting healthy actions in their lives for sustainable living practices.

Sustaining food gardens
The student teachers interviewed seven children of school-going age. They asked them about the necessity of a garden at the centre. Six children saw the importance of the gardens for growing food but one child did not see the importance of it. This child hated gardening and he did not see crops picked from the garden at the centre. This garden was small and badly maintained, with one type of crop growing. It is not surprising that this child gave a negative response. When the children were asked if it was important to have gardens at their homes, they all gave a positive response. But when they were asked if they had gardens at their homes, they gave a lack of time, money for seeds and space (land) as reasons for not having them at their homes.
Over a period of five weeks the student teachers engaged the children in organic gardening practices at the centre. The children were assigned four gardens to create and maintain. They planted seedlings that the student teachers had purchased -beans, tomatoes, carrots and spinach. The children were more willing to participate in the activities when the student teachers worked with them in the garden. The student teachers used this time as a learning opportunity where they explained the growth of plants and the effects of pests on the plants. They also explained the importance of weeding and mulching the garden. At the end of the period the plants had grown and the bean plants had started budding. The children, unfortunately were only motivated to work inthe garden when the student teachers visited the centre. The development of a positive attitude to gardening will expect a longer time frame.

Adopting healthy actions
The student teachers, Mtembi reflected that when she arived at the centre for her first visit, "the children could not hide their excitement so they started cheering at me; introducing themselves to me and telling me about their schooling" (Mtembi, September 2010). The student who worked with this project engaged the children (four children in the age group 9 – 15 years old) in developing knowledge and skills on primary healthcare and conservation practices. These needs were identified when the student teacher visited the centre and discussed the needs of the centre with the housemother. The primary healthcare looked at personal hygiene, diseases, physical activity and diet. The conservation practices looked at water conservation actions carried out by the children.
At the beginnig of the project the student teacher asked the children for their understanding of and actions with regard to healthcare and conservation of water (access to water was a problem in the area). She then used these meanings to develop a programme that they could follow to increase their understanding and actions with regard to these issues. She presented stories about healthcare practices to the children and discussed the issues highlighted with them. She analysed the lunch menu that was planned for two weeks on the presence of protein, carbohydrate and fats per meal. She used a mapping activity of the area, observed the source of water, what it is used for, how it was used and possible rainwater harvesting actions using the drainpipes of the house.
The student teacher reported that at the end of the project the children could identify the carbohydrates, protein and fat in their meal and talk very basically about their importance for their development. The children used behaviours like covering their mouths when they coughed instead of freely coughing as they did before and "they asked for cough mixture" (Mtembi, October, 2010). Before meals children are given a basin and soap to wash their hands. The children are aware that they should not wash their hands under a running tap. Mtembi stated that when a child was asked what healthcare was the response given, "is about washing your body, changing your clothes and brushing your teeth every day. Is to choose the right friends. To seek help from social workers and the hospitals and keep the utensils clean all the time". Mtembi, research report, October 2010).

CONCLUSION
The student teachers and the community for the four projects were in different contexts but in each instance the needs were identified and a suitable programme was developed on request from one group of Aged citizens and identified and observed for the other projects. The initial knowledge and skills for both the

community and the student teachers were developed and extended. The programme developed expected of the community and the student teachers to be participatory and to collaborate on taking control of their lives, the Aged with Osteo-arthritis after exercising "could do home chores and experienced less pain" (Thobe, October, 2010). The programme designed expected of the community to participate in activities that could enhance them and the student teachers were enhanced in the process as well. Being empowered is about developing a power of knowledge and skills for a better life. The student teachers expressed their empowerment of the process as they were taken out of their comfort zone of teaching children in a classroom to working with the Aged and youth in contexts different to what they had experienced before. For all the students this was their first time in an old age home or a Drop In-Centre. The integration of Service-Learning for the development of a community is a necessary and important empowering process for both the students and the community.

THEME 2
Educational Leadership in Context

3 - New Scopes for the Training of Educational Administrators, Based on a Reflection on Their Role

Lucila Mara Sbrana Sciotti

Operations Superintendent - Senac São Paulo.
lucila@sp.senac.br

Abstract[103]**:** Among several referential theoretical systems, practice disseminated inside institutions and the social relations that enclose us, there is much still to advance and to revise, towards a more balanced, fair and human world. In this context, the school, like socially recognized institution, is one of the principal social spaces of preparation of the generations.

The challenge that relapses into the school is stimulating new forms of thinking and of acting, more appropriated to the current social complexity, in the most human perspective of a society.

In this way, there becomes big the responsibility of the educational administrator in the choice of values and concepts that will give basis to the educational action.

It is important to accent the role the school administrators must fulfill, because It has been a call to revise the set of his functions, understanding them in a systemic way. It is made necessary to surpass the barrier of the division between "administrative" and "pedagogic" sectors. He must act like someone who articulates objectives, interests and propositions, with the dialog as a base.

I propose the "conversation" between the Critical Pedagogy by Paulo Freire and the Organizational Learning concepts by Peter Senge as the principal theoretical referential system for the reflection on the acting of the educational administrator.

I am starting from the premise of *understanding as a driving force of education* and I propose three elements as *areas of training and reflection for educational administration* that are integrated and that influence each other, since neither occurs apart from the other in the desired dynamics for appreciating a world of complexities. They suggest the possible development of the ability to understand, as well as developing other skills that will give genuine support to educational administrators faced with a diversity of situations to handle:

1.   PERCEPTION – This element comes up so that the need to organize individual and collective spaces for reflection is recognized and appreciated. These spaces should be based on a critical reading of the realities that are necessarily associated with goals (institutional, educational and professional).

2.   EXPRESSION – Here the care that the forms of manifestation require comes into focus when considering the importance of the role of the administrator's mediator. In this area, the ability to construct environments for dialog is highlighted, where the desired expressiveness should be of a multilateral nature.

3.   ACCOMPLISHMENT – In this training element, practice and experimentation become the central environments. Such an element is a field of practice that supports the right practice.

The proposed elements do not correspond to rigid and compartmentalized structures, but perhaps, meet the need for transposing the preponderant thinking that separates, classifies and fragments to a shreds, towards perceived unconcerned thought, which is based on understanding as its driving force.

The author will present the work that is carrying out with sixty educational administrators from Senac Sao Paulo, one of the biggest institutions of professional education in Brazil, taking the parameters above described as a base of their formation.

Keywords: Educational administration, training of educational administrators, curriculum

The proposal of this text is to reflect on the training of the educational administrator, considering the need to review the set of functions performed by this individual, and to promote training-related actions that reflect a concern with education of the future.

For some time now, I have been reflecting on the work of educational administrators and the way they conduct groups. I have worked as an educational administrator since 1998, and in 2006, I took on the responsibility of coordinating the operation of around seventy educational units in the State of São Paulo, Brazil.

It is important to place the role of the educational administrator in the context of the present day. According to Alonso (in PONTIFÍCIA UNIVERSIDADE CATÓLICA DE SÃO PAULO, 2002), the function of the

---

[103] This text translation from Portuguese to English is a free translation

educational administrator has come to be understood as a pedagogical-administrative relationship in which planning and execution are not separate or contradicting fields, since the work of administration is defined according to the proposals of the educational institution. Thus, Alonso (ibidem, p. 23) states:

> (...) the division of attributes, which is very common, in which the director is responsible for the administrative, routine, the bureaucratic work, and representation, without any commitment to the pedagogical work, seen as the excusive reserve of the teachers and teaching specialists, is unacceptable.

In the search to overcome the barrier between "administrative" and pedagogical" activities, the educational manager should, in today's social context, be committed to creating an atmosphere of dialogue in which he or she acts as an articulator of objectives, interests and proposals. Concerning this aspect, Alonso (ibidem, p. 250) states:

> In the case of the school, collective work is a more recent concern, and is not always accepted by the directors, or even the teachers who, by force of habit of working in isolation, see this as a waste of time or an additional task.

On the other hand, in the current context of sweeping social change, the concern with the future has been manifested in various reflections and proposals. The UNESCO Internal Commission on Education for the 21st Century (DELORS, 2001), for example, highlighted the importance of this debate in the field of education. His report, known as the Jacques Delors Report – concluded in September 1996 - points to education for the 21st century, indicating four basic essential pillars for a new concept of education: learning to know; learning to live together; learning to do and learning to be. Delors (2001, p.11) emphasizes that education "(...) emerges as an indispensable triumph for humanity in his construction of the ideals of peace, freedom and social justice."

THE SCHOOL AS A FIELD OF THE FUTURE

Whether together with the family, groups of friends, the working environment or the communities to which one belongs, each of us is responsible for the construction of what may appear – to the eyes of the present time – to be no more than an idea or a possibility, but which gradually takes form, based on the sum of the individual and collective acts of today: the future.

Some may see the future as a destination to which we are subject, a predetermined end that we will one day reach. This is a way of seeing that frees us from the responsibility of linking the acts of the past and the present which, undoubtedly, will comprise the future, as this is formed in the succession of decisions and actions of people, communities and institutions, added to other phenomena that may or may not be under human dominion and logic.

The concept of the future, understood based on the refusal of the present as something irrevocable brings, at its heart, *hope* as a feeling that reveals a desire for other possible contexts to be accomplished; *utopia*, as the belief in the process of human evolution, in the projection of the idea of a better, more egalitarian and fair world; and *ethics*, which is manifested in the aspiration for greater harmony between the values and principles focused on human well-being and those evidenced in the various social realities experienced. The future proposed here is one that valorizes human relations, balance in social relations, and care of the human being, with his shelter and the other systems of life present in it.

The thinking of Paulo Freire (2000, p.21) gives a basis to this form of conceiving the future, as the author considers that the conscious presence in the world:

> Means recognizing that we are *conditioned but not determined* beings. Recognizing that History is time of possibility and not of determinism, that the future, permit me to reiterate, is problematic and not inexorable. (original text)

For the author (idem, p.20), the human being has become "(...) a Presence in the world, with the world and with others." This conscious presence intervenes, alters, evaluates, resolves, breaks and (ibidem, idem)

> (...) it is the domain of the decision, the evaluation, freedom, breaking away, option, that the ethical need is instituted and responsibility is imposed. Ethics becomes inevitable and its possible transgression is a loss of value, never a virtue.

Freire (2000b) warns of the danger of accepting the fatalistic discourse that the reality cannot be changed by man, and that life, as it is, is an untouchable reality. He points out the possibility of dreaming, of desiring possible utopias, and transforming the world, which for him should be desired and operated.

To the thinking of Freire can be added that of Peter Senge (2007, p. 24), who considers the field of the future as something that may be accessed by means of presence, the capacity to be aware and attentive to the current moment and "(...) to hear intensely, to reject preconceived ideas and historical forms of lending meaning to things."

The positions of these authors relate to the possibility of transforming the present, towards a desired future, through purposeful action in the present.

Freire (idem) understands that to be able to transform the world, one must work with unity between discourse, action and utopia. For Freire, the diagnosis of the reality – the *denouncement* – should always be followed by the proposal of better solutions – the *announcement*. Concerning this question, he affirms that (idem, p.118):

> (...) when rethinking in the concrete data of reality, being experienced, prophetic thinking, which is also utopic, involves a denouncement of the way we are living, and the announcement of how we can live. It is a hopeful thinking, for this very reason. It is in this sense that, as I understand it, prophetic thinking not only speaks of what could come to pass, but speaks of how the reality is like, denouncing it and announcing a better world.

For Senge, the capacity to witness alters our perception of the world and of ourselves, and can bring an extraordinary sensation of hope, when visualizing other possibilities of giving meaning to life. The author observes that in the development of the perception lies the possibility of conduction to the state of (ibidem, p. 24) "opening oneself to receive", as a means of reaching deeper levels of learning and awareness.

To be able to perceive the future which is manifested in the present, it is necessary to look to the current moment, in a critical way, so that the social diagnosis can be accomplished. Through signals observed in the critical reading, the evils present in the social fabric become apparent. Reflection on these ills – based on the set of values focused on in the social balance and on the well-being of humans and the planet – enables alternatives for corrections and transformations to be seen. Thus, another possible route can be perceived with the mind and with the heart.

Among the various theoretical references, widespread practices within institutions, and the social context that surrounds us, there is still much to advance and review, towards a more balanced and worthy world. The school, as a socially recognized institution, is one of the main social spaces in the preparation of generations; therefore its environment can be understood as the field of the future. However, often a certain distancing is seen between pedagogical proposals that are considered as transforming, and the educational action itself.

The school that is committed to the valorization of human relations, of social relations balance and environment care, has the challenge of stimulating new forms of thinking and acting that are more appropriate to the current social complexity. Thus, the responsibility of the educational administration in the choice of values and concepts that will form the basis of the educational action becomes an important element of impact. For this, the educational administrator needs to assume his role as the main person responsible for giving shape to the educational environment. I propose, for this exercise, the following parameters:
- Education has the responsibility, as a field of intergenerational training, to build a more balanced world;
- There is a new model of society, in its relations of production and power, in the context of the so-called Information Era;
- The need is observed for theories and practices that are more appropriate for multidimensional, transdisciplinary practices and those of a local and global order;
- The educational manager should assume his role as the main person responsible for shaping the educational environment, and he must reflect on the role of joint responsibility for the student's progress, in all it's amplitude;
- The educational environment should be based on the principle of reflective action, as a form of accomplishing the praxis; interaction between theory and practice.

It is observed that the main route to be taken, in the exercise of reflecting on the professional role, is the processes of reflecting the practice, which do not affect only themselves, but require intentional organization, to constitute learning processes that are collective and institutional.

CONCEPTUAL FRAMEWORK

An important point to be highlighted is the fact that the educational administrator must see him or herself, above all, as an education professional. This is his scope of action, and the main factor in the individual relationship with the working environment.

Personally, I have found in the work of Paulo Freire the necessary ethical force – and support – for the accomplishment of educational actions geared towards human well-being and development. Freire's concepts become an important conceptual guideline, expanded by other theoretical proposals that facilitate their understanding or expand their application. The formation of a critical awareness proposed by Paulo Freire (2000a) is therefore proposed as the main guideline for the exercise of reflecting on the role of the educational administrator.

I propose a dialogue between the Critical pedagogy of Paulo Freire, and the concepts of Organizational Learning proposed by Peter Senge as a theoretical framework for reflection on the practice of the educational administrator. There are convergences between these authors, in their portrayal of the world in its multiple realities, and also in their warnings of the risks to which we are exposed. The authors present elements for the necessary reflection, aimed at individual and collective practice committed to building a more balanced world. They address the urgent need to deal with these themes and rethink our presence in the world.

For Freire (2000), educational ethics requires certain competencies that bring in their essence qualities like criticality, respect, acceptance of the new, good sense, humility, tolerance, rigor, curiosity, happiness, hope, commitment, generosity, amorousness, listening, authority, liberty, simplicity, fondness and dialog.

The teachings of Paulo Freire prompt us to reflect on the importance of professional values in view of the search for an education based on the values and virtues that enable dignity in human relations. Consciously or not, any human action is always accompanied by the set of values that each individual carries. Also in educational action, as action that is never neutral, one must not run away from the responsibility of linking the personal values with the values that reside in the pedagogical proposal to be implemented. The educational activity cannot be simply a personal choice of how to do this or that, or how to apply this or that content. As Freire (2000b, p. 25) warns, "... besides being an act of knowledge, education is also a political act. therefore, there can be no neutral pedagogy."

The clarity with which Paulo Freire addresses the question of educational ethics, the simplicity of his words, enables us to see that what appears to be a choice based on good sense is, in fact, an incessant search for coherence between thoughts, values and practice. It may seem obvious that being filled with "good intentions", the resulting actions will, consequently, be equally good. But without an ongoing commitment to pay attention and action, and accomplish the praxis, we run the risk of deviating from the way of critical reflection.

It is not a simple route, but a difficult one. It requires daily effort and ongoing evaluation of the actions carried out in relation to the thinking: theory and practice must be coherent. As Paulo Freire (2000b) teaches us, education is, above all, about *giving examples through actions*. To work in a democratic environment, one must primarily *understand* what it means to *be* democratic and *act* in accordance with this idea. If being dialogical is a necessary quality, one must know how to listen and guarantee the expression of all, in any circumstances.

The proposal of Learning Organization of Peter Senge was conceived in the world of large corporations, but it does not apply exclusively to the corporate world. It is a proposal of great value for educational administrators and educators. In his book, "Escolas que aprendem" (Senge, 2005, p. 16), bases his thinking on the idea that

> (...) a school that can learn has become more predominant in recent years. It is becoming clear that schools can be recreated, vitalized and renovated in a sustainable way, not by decree or order, or by supervision, but by the adoption of a learning orientation. This means involving everybody in the system in expressing their aspirations, building their awareness and developing their capacities together.

For the author, a learning school represents an approach that stimulates hope, since (ibidem, p. 18):

> (...) schools are increasingly expected to compensate for the changes in society and in the family that affect the children: changes in family structure, rapidly changeable trends in the culture of population television, unending commercialism, poverty (and the malnutrition and inadequate healthcare that accompany them), violence, child abuse, teenage pregnancy, drug abuse, and the incessant social revolt.

However, Senge, also gives us a warning (ibidem, p. 18):

> (...) Even so, the schools also are also facing intense pressure to slow down the change, to be conservative, to reinforce traditional practices and at the same time, not to leave anybody behind.

Peter Senge proposes the five disciplines of Organizational Learning as a *strategy for assisting the work of Critical Pedagogy*, in light of Freire's teachings (ibidem, p.126):

> The emerging language of the five disciplines can provide strategies for those seeking to practice a critical pedagogy. Combining these two bodies of theory and practice, always keeping in mind the underlying philosophies of these practices, educators and develop new practices to "read the world", acquiring the multiple illiteracies necessary to change practices that are deeply rooted that prejudice many students.

The conceptual bases of Organizational Learning proposed by Senge are found in his book ""The Fifth Discipline" (2008):
- *Personal Mastery*: discipline, understood as the articulation of a coherent image of the personal vision with a realistic vision of the actually reality, in a way that (idem, p.41) "clarifies and deepens our personal vision, focuses our energies, develops patients and sees the reality objectively";
- *Mental Models*: this discipline focuses on the development of the awareness of attitudes and perceptions, seeking to (ibidem, p. 42) "(...) learn and unearth our internal images of the world, bring them to the surface, and keep them under rigorous analysis";
- *Shared Vision:* establishes focus in the common proposal, as it is considered (ibidem, p.43) "(...) difficult to think of an organization that has kept itself in a position of greatness, without having goals, values and missions that are deeply shared within the organization";
- *Team Learning*: discipline of group interaction, since (ibidem, p.44) "Learning as a team is vital, as teams, not individuals, are the fundamental learning unit in modern organizations. This is a crucial point: if the teams do not have the ability to learn, then neither will the organization";
- *Systems Thinking*: discipline considered as the cornerstone of the learning organization, this fifth discipline can help the leader with the forces that mould the consequences of the actions, as (ibidem, p.97) "(...) to understand more complex administrative issues, it is necessary to see the entire system responsible for the problem."
Many of the educational environments are still a stronghold of proposals focused on authoritarianism, ready answers, the application of methodologies and technological resources without discussion, and a lack of communication between all those involved (directors, coordinators, teachers, students, employees, parents). I fear that many curricula, whether more traditional or more innovative, have as a prospect a future that is not much different from the present time, as they are based on the predominant model of thinking, authenticating it, whether deliberately or not.
The problems of the present time require a look at the system in itself, to reevaluate and subsequently identify solutions by the parties that comprise them, in a dialogical form, for the composition of more worthy realities. But – it must always be stressed – there is no random chance or spontaneity that takes account of this challenge. Thus, the school, as an organization, needs its main leaders to promote deeper reflection on the reality, in order to be able to take bigger steps towards a future with greater social balance. In this quest, I believe that the foundations of Organizational Learning are presented as a support strategy for educational administrators, for the application of Paulo Freire's Critical Pedagogy.
The scenario formed by the theoretical references presented here instigates thinking to return to more integrating compositions in regard to the conceptual parameters and the forms by which educational administration is practiced. In the visualization of possibilities, other dimensions can emerge, in the route of educational administration as a complex that groups and brings together the various scopes that characterize it.

OTHER DIMENSIONS FOR THE TRAINING OF THE EDUCATIONAL ADMINISTRATOR
Considering the challenge of overcoming the barrier between the *pedagogical* and the *administrative*, I observe that Paulo Freire's Critical Pedagogy and Peter Senge's Organizational Learning enable interaction between these two fronts, in a harmonious way, enabling the recognition of a complex and challenging set, in relation to the various activities of the educational administrator.

I propose three dimensions as *scopes of training and reflection for educational administration,* which are integrated and interposed, since none occurs without the other, in the ideal dynamic for the appreciation of a world of complexities. They suggest the possibility of developing the capacity to *understand,* as well as the development of other competencies that could give the due support to the educational manager, faced with the diversity of situations to be managed:

- PERCEPTION – This dimension involves recognizing and appreciating the need for the organization of individual and collective spaces of reflection. These spaces should be based on critical readings of the reality, which must be associated with objectives (institutional, educational, professional), as they can show responses to questions that emerge from this immersion in the surrounding reality. Here, the thinking that combines reason and emotion is highlighted.
- EXPRESSION – the capacity to build an atmosphere of dialogue, in which the desired expressivity should be multilateral. The care that the forms of manifestation require comes into focus, considering the importance of the administrator's role as mediator. Given that their capacity for communication reveals sentiments and values, improvement should be an ongoing goal.
- ACCOMPLISHMENT – In this training dimension, practice and experience become central ambiences. This dimension is a field of practice, as support of the practice itself. It is in the scope of the conversation of ideas in actions that the working cycle is closed, and that reveals what was possible to achieve. The actions materialized bring to the surface what is in fact valorized, and enables the coherence between concepts, plans and actions to be seen.

The proposed dimensions do not correspond to rigid, compartmentalized structures, but perhaps meet the need to transpose the predominant model of thinking – characterized by separation, classification and fragmentation – in favor of a deductive form of thinking in which *understanding* is the driving force.

In my work at Senac São Paulo, a professional education institution, these have been the main references for the practice. The use of methodologies geared towards the collaborative environment facilitates this exercise, like World Café (Brown et al, 2007) and Appreciative Inquiry (Cooperrider, 1999). In this form of conducting things, the training of educational administrators – and their teams – is understood as an ongoing activity. The proposal for reflection on the practice is permeated by the conceptual framework, the indication of methodologies, the indication of readings, and references of specialized professionals who can bring their visions to the groups in lectures and other types of activities.

The exercise of this practice requires clear and purposeful planning of actions, daily effort, and ongoing evaluation of the actions carried out. Values are not established by chance. They need to be proposed and assumed, individually and collectively. Only in this way can they be incorporated, becoming part of the culture of a team and of an institution.

5 - Enhancing Teachers Agency with Valuing Them: The Link Between Teacher-rated Servant Leadership of Principals and Teachers' Perceived Empowerment

Khalil Gholami[1] and Sara Hajizadeh[2]

Department of Education, University of Kurdistan, Iran
[1]Khalilgholami2002@yahoo.com
[2]sarahajizadeh@ymail.com

Abstract: The main research task of this study was to examine the association between the servant leadership characteristics of principals and teachers' empowerment. Of the total number of teachers (N=310) in Mahabad's High schools, 173 teachers were randomly selected from all schools. Servant Leadership Assessment Instrument including six sub-scales (Agapao love, Humility, Altruism, Vision, Service and Trust) and Empowerment Inventory were used in order to collect data.
Results suggested that there was a statistically significant positive and strong association between teacher-rated of the subscales of Vision, Trust, and Altruism of principals and perceived empowerment of teachers. These three sub-scales were found to predict more than 70 percent of variance of the perceived empowerment. The other sub-scales had no statistically significant association with the teacher-perceived empowerment.

Keywords: Agency, Servant leadership, Empowerment.

INTRODUCTION

Agency is a social theory referring to an individual's capability to make decision and act according to her interests and desires. "The theory's main assumption is that human beings by nature are selfish, thus agents and principals will most probably have differences in interests and attitudes towards risk, leading to divergent decision-making preferences" (Eisenhardt, 1989 cited in Cohen & Baruch, 2010, p. 187). Schools' structure and principals' leadership styles may sometimes conflict with teachers' agency in such a way that teachers may not have enough possibilities to exercise their capabilities effectively. Thus teachers fail to have internal motivation to collaborate in .the school community.

Empowerment as a new way to motivate employees and organizational human resources is an up to date subject in management. Researchers and managers are increasingly interested in empowerment and managerial measures based on it (Spritzer, 1995; Mishra, 1992 cited in Hazrati, 2008). For the first time Conger and Kanango (1988) presented an operational definition of empowerment. They believed that empowerment is process of individuals' self-competence development in organization through identifying unfair conditions -indicating lack of power for them- and try to overcome these conditions by formal organizational activities, informal ways, and providing effective information. Empowerment according to Spritzer, 1995; Mishra, 1992 cited in Hazrati, 2008) has five basic dimensions: competence, self-determination, impact (personal consequences), trust, and personal relevance.

Like other organizations, empowerment is one of prominent factors playing a great role in success of school. Teachers' empowerment depends on leadership approach governing educational environment in school. For example several research showed that principals' leadership was related to teachers' organizational commitment, professional development, job stress and job satisfaction (Dono – Koulouris, 2003; Estep, 2000; Nir & Kranot, 2006). Such research suggested that leadership is a managerial issue concerned with relationship (Hoy & Miskle, translated by Seid Abaszadeh, 2008; Robins, translated by Parsaian & Arabi, 2007; Yukle, 1992). Effectiveness of leadership and followership are reciprocal. Sendjaya and Sarros (2003) believed that leadership was not to use power against follower but for helping them. Servant leadership is one of the theories emphasizing on the effective and mutual relationship between leader and followers. In 1970, Robert Greenleaf (1904-1990) propounded servant leadership in a paper entitled "servant as leader". He focused on servant leaders' motivation as one of leadership characteristics to serve or lead.

Servant leadership has several characteristics (Barbuto &Wheeler, 2006; Greenleaf, 1977; Laub, 1999; Liden, Wayne, Zhao & Handerson, 2008; Page & Wong, 2003; Patterson, 2003; Russell & Stone, 2002; Spears, 1998). Patterson (2003) presented a model of servant leadership including the following components:

Agapao love, Humility, Altruism, Vision, Service and Trust. The figure 1 shows how these dimensions are related to each other:
Figure 1: Servant leadership, Peterson, 2003, p. 10

Servant leadership with such characteristics may improve employees' empowerment and thus their agency in organizations such as schools and other educational contexts. Stephen (2007) believed that although schools' leadership approached has dramatically changed and it is difficult to predict which leadership style may guarantee the success of school, apparently servant leadership affected success of schools. Principals with servant leadership behaviors were found to provide good environment to enhance the teachers' empowerment in different ways (Dennis, 2004; Greenleaf, 1977; Lintner, 2008; Lobe, 1999; Peterson, 2003; Short, 1994). Bredson (1998) showed that influential principals affected teachers' profession through ways such as allocating time, money and enough space, assuring teachers to have valuable ideas and offerings, being accessible, behaving intimately and informally, and creating friendly, supportive and open environment resulted in teachers' empowerment (cited in Lintner, 2008).

Although servant leadership had a long record in management field, Barbuto and Wheeler (2002) believed that it had not been examined as a leadership approach in educational management field. Therefore, it should be studied in educational context in terms of different variables. Therefore the present study examined relationship between teacher-rated servant leadership of principals and perceived empowerment of teachers in order to gain an insight into the topic in the teaching and teacher education context. Consequentially, following questions are proposed:

   To what extent was the teacher-rated servant leadership of the principals associated with teachers' perceived empowerment?
   To what extent did the subscales of teacher-rated servant leadership of principals predict teachers' perceived empowerment?

METHODOLOGY

Participants
Population was teachers (N=310) who taught at high schools in Mahabad, Iran during the academic year 2010. 173 teachers out of this population were selected as the sample based on Krejce and Morgan table (Biabangard, 2005). The teachers were both male and female from all high school in the city (Mahabad). High schools in Iran's educational system refer to the level of schooling in which students follow three main areas: Humanities, Empirical Sciences, and Mathematic. Teachers in such schools are specialized and thus each teacher teaches a particular subject matter. Each school typically is officially and organizationally led by one school's headmaster (principal) and two vice-principal. In this study, the participating teachers rated both the principals in terms of servant leadership and their own empowerment.

Measures
Servant Leadership Assessment Instrument: This questionnaire was provided by Dennis and Bocarnea (2005) based on Peterson's servant leadership characteristics. It has 33 items including six subscales; Agapao love, Humility, Altruism, Vision, Service and Trust. Reliability coefficient 0.70 and 0.89 to 0.94 had been reported for questionnaire and components respectively.
2.2.2. Teachers' Empowerment Assessment Questionnaire: This questionnaire was provided by Hazrati (2008). It has 25 items including and measure the amount of individual's competency, meaningfulness, self-determination and effectiveness. Reliability coefficient 0.91 has been reported for this questionnaire.

Statistical analyses
Given that the data reflected a multilevel structure of principals (level 1) nested within teachers (level 2), principals were not independent observations. To take into account the clustering of observations, I used

multiple linear modeling. Since there was no theoretical reference to prioritize the variables, I applied Stepwise Regression in order to analyze data. In this case, the independent variables were entered into model based on the highest correlation that they had with dependent variable.

Therefore, I first conducted a Person correlation to measure the bivariate relationship between the subscales of servant leadership and teacher empowerment. Then I did the Stepwise Regression analysis to estimate the predictive power of the subscales of servant leadership in terms of teacher empowerment. In order to examine the individual influence of each subscale of servant leadership, multicollinearity was checked based on Tolerance and Variance Inflation Factor (VIF).

RESULTS
Bivariate and partial Correlations
Pearson correlation of the overall scores of teacher-rated servant leadership of principals and their perceived empowerment was calculated and the results showed that there was strongly positive relationship between principals' tendency towards servant leadership and the teacher empowerment (r=0.82, p<0.001). In other words, the teacher-perceived empowerment increased when the teachers rated their principals with high tendency toward servant leadership. For more details bivariate and partial correlations were applied to show relationship between teacher-perceived empowerment and subscales of servant leadership. Table 1 shows the results:

Table 1: Bivariate and partial correlation between the perceived teacher empowerment and the teacher-rated servant leadership of principals

Subscales of servant leadership	Bivariate correlation		Partial correlation	
	Correlation coefficient	significance	Correlation coefficient	significance
Service	o.67 ***	0.000	-0.19 *	0.01
Humility	0.70 ***	0.000	0.18	0.17
Altruism	0.77 ***	0.000	0.15	0.054
Trust	0.78 ***	0.000	0.26 **	0.001
Agapao love	0.80 ***	0.000	0.11	0.54
Vision	0.81 ***	0.000	0.35 ***	0.000

p<0.05*, p<0.01**, p<0.001***

As in table 1, bivariate correlation shows that there is strongly positive relationship between perceived teachers empowerment and subscales of servant leadership: Vision and Service received the highest (r=0.81) and lowest (0.67) correlation respectively. Partial correlation however shows considerable decrease of correlation. It means if the effect of each subscale is independently measured while controlling for the effects of other subscales, the association between subscales of predictive variable with dependent variable will dramatically decrease.

As it can be seen correlation coefficients of three subscales Service, Trust, and Vision with empowerment are statistically significant even after conducting partial correlation but the other three subscales failed to show statistical significant relationship. Unexpectedly there was a negative statistical significant relationship between Service and empowerment (r= -0.19, p= 0.05). It means if other subscales of leadership are controlled, there will be reverse relationship between Service and empowerment: the more principals were seen to show behavior associated with Service in their leadership, the less teachers perceived their empowerment.

Regression analysis
The variance estimation of model
Multiple regression (stepwise) was calculated to predict teachers' perception of their empowerment by dimensions of teacher-rated servant leadership of school principals. . The results showed that the three subscales Vision, Trust, and Altruism yielded significant prediction power and thus included in the prediction equation. These three subscales of servant leadership could altogether predict 72% of the variance in teacher-perceived empowerment, (R^2= 0.73). The subscales Service, Agapao love, and Humility showed no statistical significant prediction power and thus excluded from the model.

When the strength of predication was evaluated for significantly predictive subscales in three steps based on their correlation coefficient (the strongest correlation got priority to entered into model), the results showed that Vision could predict 69% (R^2=0/66) of the variance of teacher-perceived empowerment. The subscales

Trust and Altruism could improve the model with 6% ($R^{2\ change}$=0/06) and 1% ($R^{2\ change}$=0/01) of estimating variance of teacher-perceived empowerment respectively. Table 2 shows these results:

Table 2: The predication power of teacher-rated servant leadership of principals

Model	R^2	SD error	$R^{2\ change}$	F change	df	Sig
Vision	0.66	7.590.	.66	326.31	1,169	0.000
Trust	0.72	6.94	0.06	33.61	1,168	0.000
Altruism	0.73	6.84	0.010	6.04	1,167	0.000

Dependent variable: teacher-perceived empowerment of teachers' empowerment

F value (ANOVA) for the model in each step showed significant prediction equation: Vision, F (169, 1) =326.31, p<0.001; Trust, F (168, 2) =211.45, p<0.001; Altruism, F(167,3)=147.21, p<0.001.

Coefficient weights of predictive variables in the model
To determine the individual predictive power of each subscale, multicollinearity or overlapping predictive effect of subscales was checked. Looking at table 3, it can be seen that multicollinearity is not a problem: all tolerance values are above 0.10; all VIF (Variance Inflation Factors) values are below 10.

Table 3: Coefficient of teacher-perceived servant leadership' scales of principals

Subscales	B	Beta	t	sig	Tolerance	VIF
Vision	1.20	0.41	3.46	0.000	0.26	3.76
Trust	0.99	0.32	1.94	0.000	0.36	2.75
Altruism	0.78	0.18	4.76	0.01	0.27	3.59

Dependent variable: teacher-perceived empowerment of teachers' empowerment

In examining the **Beta** weights (standardized regression coefficients), it can also be seen that all three subscales of servant leadership were rated to be significant predictors of teacher-perceived empowerment (p<0.05). The subscale Vision had the highest effect of teachers' empowerment (β=0.41, t.346, p<0.0001): thus, the more the teachers saw their schools' principals with behaviors related to Vision, the high they perceived their empowerment. Among these three subscales Altruism had the least relationship with and thus predictive effect for teachers' empowerment (β=0.18, t=4.76, p<0.05).

DISCUSSION AND CONCLUSION
Servant leadership is one of leadership approaches emerged in line with existing literature of leadership. This leadership approach is based on such leadership epistemology that a good leader prefers needs and goals of organization and staff to his (Woodruff, 2004) and emphasizes on expanding followers to promote their abilities to accept greater responsibilities in organization and work conditions (Stone & Patterson, 2003).

In educational context, the effect of servant leadership components and behaviors have been examined in terms of several variables such as teachers' self-efficacy (Bandura, 1997; Nixson, 2005), developing teachers' insight towards positive role enactment in school (Patterson, 2003) and creating trust among teachers to empower themselves (Farling, Stone & Winston, 1999). In consistent with these studies, this study generally showed that the teacher-rated servant leadership of school principals was positively associated with the teacher-perceived empowerment of teachers' empowerment.

Considering the isolated effects of servant leadership subscales, the results showed that Vision, Trust and Altruism had significant effects on perceived empowerment of the teachers. This means if the principals try to take teachers' opinion into consideration and thus trust them in the process of decision-making for developing school, the teachers will find themselves effective, helpful and positive in the school community. This result is in consistent with results of Chacon (2005), Laub (1999) and Moor and Esselman (1992); trusting teachers to participate in decision making process of school leads to their self-efficacy (one of servant leadership subscales).

On the other hand, other subscales of servant leadership (Service, Humility, Agapao love) failed to show a significant prediction in regarding to perceived empowerment of the teachers. This is due to fact that quantitative methods may not solely be appropriate to examine the complexity of servant leadership in terms of teacher empowerment. In many cases, the statistical reliability and validity of the scales might be artificial and thus may not examine what they address. In this study, for example, the multicollinearity of subscales Service, Humility, and Agapao love was a problem and thus it was difficult to isolate their individual effects on teacher empowerment. In addition results of this study confirmed that these dimensions servant leadership (Service, Humility, and Agapao love) are somehow unreal and ideal. This part of results is in consistent with

other researchers' findings. Jhonson (2001) believed that servant leadership was unreal resulting in passive and most times wrong behaviors between staff. Moreover, Bowie (2000) stated that servant leadership was credulous and incredible.

In general, subscales Vision and Trust are more authentic and also considered as dimensions of other leadership styles such as distributed leadership. A meta-analysis on the nature of these two subscales shows that they are two basic interrelated components of school professional development in terms of how teachers collaborate in the school community. Vision is generally related to making decisions about the important professional development programs of the school and trust is a necessary property of the school leaders with which teacher collaboration is improved in terms of the school development plans. In this way when the school principals trust teachers in the process of school development, it helps teachers improve their agency in different ways. However, other subscales, e.g., Agapao love, are somehow dreamlike in an organizational context such as school and thus showed no significant contribution to the teachers' empowerment. Jhonson (2001) in this case argued that servant leadership was not efficient in all contexts and thus failed to be powerful in some cultural and organizational conditions.

In line with the results of this study, it is suggested that other researcher conduct qualitative studies to examine the nature of servant leadership contribution in terms of different issues in the educational context.

17 - A Study on Perceived Principal Support and Principal-Teacher Communication with Teacher Job Satisfaction among the Key High School in Xi'an, China

Tang Keow Ngang

School of Educational Studies, Universiti Sains Malaysia, Penang, Malaysia
tang@usm.my

Abstract: A descriptive correlation study using questionnaire was conducted in 2008 to assess the perceived school principal support, school principal-teacher communication and teacher job satisfaction which were the key variables that guided the study. Respondents were 297 teachers from 20 key high schools. Data were analyzed descriptively through the use of the Statistical Package for Social Sciences (SPSS) program. The results reveal that the key high schools of the Xi'an city have average level of teacher job satisfaction with mean score of 2.93, perceived school principal support with mean score of 2.84 and school principal-teacher communication with the mean score of 3.20. Pearson *r* test shows that there is a positive significant but moderate weak relationship between perceived school principal support (r = 0.386, p<0,01) and principal-teacher communication (r = 0.493, p<0.01) with teacher job satisfaction. There is a negative significant but weak relationship between perceived school principal support and principal-teacher communication (r = -0.251, p<0.01). Regression analysis shows there are 3 predictors namely job relevant communication, upward openness communication and perceived school principal support explains 48.7% of variance in teacher job satisfaction. The best predictor for teacher job satisfaction is job relevant communication (β= .566, p<0.01).

Keywords: Perceived school principal support, school principal-teacher communication, teacher job satisfaction

INTRODUCTION

The role of school administration contributes to the successes of the students' gained knowledge. In this context, a school administrator has to face more difficult tasks and challenges. Principal plays a variety of roles in leadership, administration, communication, support, and ability to gain support from various stakeholders. Principals are the leader of school, so their actions are noticed and interpreted by others as what is important. A good school principal must have a clear goal and vision, where his/her school is heading and knows the desirable direction, and on the path that should be taken by using the available resource and translating it into the real action (Xia, 2006). However, a school principal alone cannot achieve the goal of school, but has to support and work together with teachers. Principal's support is a part of principal leadership.

For the purpose of school effectiveness and improvement, schools like other organizations, must be cooperative, cohesive, efficient, and well managed (Tschanneen-Moran and Hoy, 2000), it needs to have successful reformation, and the relationship or interaction between the school principal and the teachers is of great importance. Effective communication at work places contributes significantly towards the performance of employees. Communication is considered as a supportive behaviour. It gives rise to enhanced job satisfaction, a good feeling of personal accomplishment and increased productivity. (Talha & Qaiser, 2004).

According to Bryk and Schineider (2003), good schools depend heavily on cooperative endeavours. Relational trust is the connective tissue that binds individual together to advance the education and welfare of students. On the other hand, concern and care about teachers from the school principal will lead to teachers' commitment to the school. Rhoades and Eisenberger (2002) found that when the organization values the employees' contribution and cares about their well-beings, it serves an important source of socio-emotional resources (such as respect, caring); these would increase employees' felt obligation to help the organization reach its objectives. Employees' affective commitment to the organization, and their expectation that improved performance would be rewarded. In schools, Blasé and Blasé (1997) suggested that effective school principal can also promote teachers' work through supportive personnel characteristics.

This study emphasized the importance of a good relationship between school principal and teachers. However, most principals do not see or understand the long-reaching effects of this relationship. There are those who feel constraint by the very nature of their work; for example the unlimited paper work and rules

and regulations of the Ministry of Education. There are also those who can see and understand, but lack the skills needed to build and develop a good relationship, especially perceived principal support and principal-teacher communication in building teachers' trust in him/her (Lim Sothea, 2005). If certain decision made perceived to be fair and supported by the organization members, therefore can cause the increment of teachers' motivation, attitude, performance, commitment and satisfaction and at the same time reducing the teachers' intention to leave. Furthermore, determining teacher quality has become a critical focus for public school administrators in China. Therefore job satisfaction is playing a key role in the teacher turnover process and it would dramatically affect the performance of the teachers. That required additional regards and became a most important part of principal's responsibility.

BACKGROUND OF THE STUDY

The Compulsory Education Law of China calls for each child to have nine years of formal education. To meet this requirement, a child will attend either five years of elementary education, followed by four years of junior middle school, or six years of elementary education, followed by three years of junior middle school. Today in China, the second system, or ``6-3'' system is the more commonplace. While the Compulsory Education Law calls for each child to have nine years of formal schooling, it is recognized that certain realities prevent this nine year standard to be implemented immediately. Therefore, a provision of the Education Law is that China shall be divided into three categories: cities and economically developed areas, towns and villages with medium development, and economically backward areas.

In China, the education is divided into three categories: basic education, higher education, and adult education. Basic education in China includes pre-school education, primary education and regular secondary education. Preschool, or kindergarten, can last up to three years, with children entering as early as age three, until age six, when they typically enter elementary school. The academic year is divided into two semesters. Secondary education is divided into regular secondary education and vocational and technical secondary education. Regular secondary education consists of junior middle school and senior middle school. Junior middle school will involve either three or four years of schooling, depending on the system (6-3 versus 5-4), and senior middle school is, in the vast majority of cases, a three year program, resulting in a 5-4-3 or a 6-3-3 system of elementary school-junior middle school-senior middle school. The academic year for junior middle school consists of 39 weeks of instruction, with one week in reserve. The academic year for senior middle school is made up of 40 weeks of instruction, with one to two weeks in reserve.

Junior middle school graduates wishing to continue their education take a locally administered entrance exam, on the basis of which they will have the option either of continuing in an academic senior middle school（high school） or of entering a vocational secondary school. Vocational schools offer programs ranging from two to four years and train medium-level skilled workers, farmers, and managerial and technical personnel. Technical schools typically offer four-years programs to train intermediate technical personnel. "Schools for Skilled Workers" typically train junior middle school graduates for positions requiring production and operation skills. The length of training is typically three year.

Key high schools' principal normally is instated directly by the department of education of Xi'an. Under principal, there are three deputy principals, deputy principals is nominated by principal and approved by department of education. Then the principal can built his managerial team. The principal has the power of recruitment, the power of financial management and the power of educational management. The deputy principals are the assistant of principal, who need to take charge in these three aspects of school managerial affair. The principal get the detail information from deputy principals then give the comment of how to processing the work. Thus, the principal in a key high school have an absolute authority.

Teachers in key high schools are divided through two ways. First, each teacher belongs to their own grade group, each grade group had a head teacher, and the head teacher takes charge in daily management of teacher affair. Second each teacher also belongs to their teaching subject group, such as Mathematics group and English group. Each semester, every group need to have 3 meeting at least to sharing teaching experience, new technology, or some new issues in that particular area.

With regard to higher education, Xi'an ranks third in the country next to Beijing, and Shanghai, It is also an important base of scientific research centre in China. The Chang'an college Town, which is now under construction, will be a great appeal to hundred thousands of students from around the country. The development of private education in Xi'an is also ahead of other regions of the country. After the implementation of the reform and opening-up policy, the first private institute of higher education was founded in Xi'an. With this environment of higher education and higher proportion of students entering university, more and more students from other cities and provinces in burst into Xi'an high schools. Till today there have been five institutes each of which keeps an enrolment of over 10,000 students.

Owing to the academic year which The Law of Compulsory Education required only 9 years, that means not everyone has the ability and opportunity to enter the university throw studying in high school, and with Xi'an's profound educational background, the high schools especially the key high school got the higher solicitous from the parents and public, the teacher's performance loom large significant. A teacher's satisfaction with his or her job may have strong implications for student learning. Specifically, it may influence the quality and stability of instruction given to students. Though the student's achievement is gained in the class through the teaching of teachers, the role of school administration also contributes to their successes. In this context a school principal has to face more difficult tasks and challenges. The role of school principal must be able to pay attention to how to fulfil the expectation and accelerate the teacher's performance.

Statement of Problems

Seeing that the China educational system is one of centralization, most school principals seem to think that their most important and only duty is to carry out instructions from the Ministry of Education, and they do not seem to see the need to allocate time to develop their relationship with the school teachers. They focus much on the administrative side of their job, and do not think there is a need to show their supportive behaviour to their school teachers. But for teachers, as an ordinary human beings, they need positive attitude and commendation when they done things well, it is a basic psychological emotional requirement (Educational Annual Survey Report, 2004). Because of traditional culture in China, the leaders are always big man, they have absolute authority and power, they are serious and august，they don't unveil their attitude easily, so it is difficult for subordinates to get positive comment from them, and most of the subordinates just do what as their leader said. This bad customs is an obstruction to a job creative performance (Educational Annual Survey Report, 2004). Lack of perceived support from principal can lead teacher dissatisfaction in aspect of emotional needs and high rate of job burnout.

Friendly, relaxed, attentive, open-minded, and better communicators were the one who were able to make their teachers more satisfied with their work (Jabnoun & Fook, 2001). Because of this superior-subordinate relationship; there is hardly or very little flow of free communication between school principals and their school teachers in today Xi'an key high school. The school teachers are sometimes not informed about the happenings in the school. There is always a big gap between principal and school teachers, they hardly sharing feelings, emotions, attitudes, opinions and information, it is really an obstruction of school effectiveness and improvement.

Owing to the quality of education that the society required become more and more rigorous. The government's and the parents' position concerning the job performance and efficiency of the teachers; they accuse the teachers of negligence, laziness, lethargy, and lack of dedication and zeal to work. But a school is a whole system, if it occurred foregoing status, we cannot blame fault all on teachers (Zhang, 2001). But as a decision-maker of schools，the principal can not only care about the proportion of students entering schools of a higher grade, or how much does school earn every year, but also deeply thinking about what should they do in order to make their teachers more enthusiasm and how can they support the teacher's job and make them satisfied (Zhang, 2001). They should take advantage of their working power and administrative ability to improve such the situations.

Rosnani Jusoh (2003) concluded that teachers are the pulse and the motivator to achieve the school aims need to be well managed and the role for this should be carried out by the principal or headmaster as personnel manager as in school in alignment with the role of personnel manager in other organizations. School principals should realize the importance of having a good relationship with the teachers and should learn the skills needed to do so. With the increased of school principals' support, the principal-teacher communication in their principals and teacher job satisfaction will also be enhanced greatly. Therefore, this study intends to access the determinants that influence teacher job satisfaction in the specific cultural environment of Xi'an.

Research Objectives

Based on the problem stated above, this research intends:
a. To identify the level of teacher job satisfaction in the Key High Schools in Xi'an.
b. To identify the level of perceived school principal support existing in the Key High School in Xi'an.
c. To identify the level of school principal-teacher communication existing in the Key High School in Xi'an.
d. To identify the relationship between the level of perceived school principal support and the level of teacher job satisfaction.

e. To identify the relationship between the level of school principal-teacher communication and the level teacher job satisfaction.
f. To identify the relationship between the level of perceived school principal support and school principal-teacher communication.
g. To identify the predictors of teacher job satisfaction.

LITERATURE REVIEW
Bogler (2001) in his research indicated that the factors affecting job satisfaction can be broadly categorized as environmental and psychological. Environmental factors refer to characteristics of the job itself or the working environment such as the physical aspect of the school rules and regulation, supervision, salary and interpersonal relationship. This antecedent is also known as extrinsic motivator. The psychological factors which are also known as intrinsic motivator refers to aspects of work, such as achievement, recognition, the work itself, responsibility and opportunity for advancement. Zembylas and Papannastasiou (2004) carried out a research to determine if the level of satisfaction of Cyprus teachers was related to their personal characteristics, their school characteristics as well as their motivation to remain in the profession. The results showed that the majority of teachers in Cyprus chose the profession for extrinsic reason such as the salary and long holidays. The study also confirmed that teacher motivation either intrinsic or extrinsic is related highly to job satisfaction.

Cotton (2001) indicated that job satisfaction is essentially a cognitive evaluation that individuals make in relation to their work experiences. Therefore, job satisfaction is an index of positive and negative work experiences. In accordance with the health organizational approach, the occupational well-being of an individual consists of three components, namely job satisfaction morale (refers to positive feelings that individual's experience) and distress (refers to negative feelings that individual's experience). Thus, job satisfaction refers to the overall judgments employees make, while the underlying levels of morale and distress exert a major impact on important employee and organizational outcomes. A study done by Darwish (2002) on job satisfaction as mediator of the relationship between role stressors and organizational commitment found that job satisfaction directly and positively influenced affective and normative commitment and negatively influences continuance commitment. Also, job satisfaction mediated the influences of role conflict and role ambiguity on various facets of organizational commitment, except continuance commitment.

Makanjee, Hartzer and Uys (2005) indicated that perceived organizational support is regarded as the assurance that must be available from the organization when it is needed to carry out ones' job effectively. Taking into consideration the latter, the general physical environment within which radiographers performed their tasks in this study was rated as moderate. However, from a quality service rendering perspective it can be rated as poor, because the conditions do not meet the staff and patients' needs. Also, the non-availability and lack of equipment maintenance has direct negative impact on staff and patient safety.

Tang's study (2008) on 418 trained teachers from 65 daily based secondary schools from the state of Penang, Malaysia, 81.5% indicated a median level of principal's support upon the teachers. Thus, there is an existence of significant relationship between principal support with teacher organizational commitment (r = 0.756; p = 0.00) with apparent negative relation with the intention of teachers to leave (transfer) (r = -0.518; p = 0.00). The findings indicated that there is significant relationship between the perceived principal support with the teachers' trust on organization (r = 0.751; p = 0.00). Furthermore it was found that the organizational trust functions as moderator in the relationship between organizational support and teachers' commitment. Aselage and Eisenberger (2003) indicated that perceived organizational support is also valued as assurance that aid will be available from the organization when it is needed to carry out one's job effectively and to deal with stressful situations.

Goris, Vaught and Pettit (2000), in a study investigating the effects of communication direction on job performance and satisfaction, found that 23 of the 27 correlation ratios concerning the association of communication direction (upward, downward, and lateral) with job performance and job satisfaction were negative. Piccolo and Colquitt (2006) found that leaders could influence perceived core characteristic levels by changing the language, imagery, and symbols used to communicate meaning on the job. Goris (2004) in his research indicated that satisfaction with communication received weak support as a moderator of the individual-job congruence association with both performance and satisfaction. Nevertheless, this investigation showed that satisfaction with communication may have a significant, predicting influence on both job performance and job satisfaction.

METHODOLOGY

This is a descriptive correlation study on perceived principal support, principal-teacher communication and teacher job satisfaction. This research utilizes quantitative research methodology involving a sample of 20 key high school teachers. The 20 key high schools have a total number of 1703 teachers as by January 2008. A simple random sampling was used. A total of 317 teachers were selected from the population of permanent trained teachers who are working in 20 key high schools of Xi'an. The researchers managed to collect 300 questionnaires out of 317 that were distributed, giving the response rate of 95%.

The job satisfaction and perceived principal support were assessed using a 36 items scale adapted from Spector (1997), 8 items scale adapted from Eisenberger et al. (1986) respectively and principal-teacher communication was assessed using a 24 items scale adapted from Miles et al. (1996). All the 68 items were measured with a five point Likert scale (1 = strongly disagree, 2 = disagree, 3 = moderate agree, 4 = agree and 5 = strongly agree). A structured self-administered mailed survey questionnaire was used as an instrument for data collection.

A pilot study to validate and improve the instrument was conducted in one school. Improvement was made on the questionnaire regarding the accuracy in measurement, appropriate terminology used, and the structure of sentence used to avoid confusion. Thirty trained and experienced teachers from Baoji No.1 high school in the neighbouring city Baoji were selected as subjects in the pilot test. These teachers had the same socio-demographic characteristics as the actual research sample. Exploratory Data Analysis (EDA) was used to explore the data, followed by a reliability test. The same alpha value of 0.63 ($\alpha = 0.63$) for Section A and B was the score for job satisfaction items and perceived principal support items respectively, whereas an alpha value of 0.62 ($\alpha = 0.62$) for Section C was the score for items on the principal-teacher communication. In other words, the variables used in this instrument are found to have moderate high reliability value but the instrument was still acceptable.

Descriptive and inferential statistical analyses were then employed using the Statistical Package for the Social Sciences (SPSS). Descriptive measures such as mean and standard deviation were used to describe the variables in the levels of the teacher job satisfaction, perceived principal support and also the level of principal-teacher communication. The Pearson Product Moment correlation analysis was used to determine the correlation between the three key variables namely teacher job satisfaction, perceived principal support and principal-teacher communication. A multiple regression analysis was used to identify the predictor of teacher job satisfaction.

FINDINGS

Level of Teacher Job Satisfaction, Perceived Organizational Support and Principal-Teacher Communication

Results based on Table 1 show respondents' perception on the level of their job satisfaction, perceived principal support and principal-teacher communication. Among the three key variables in this study, the highest mean score is on the principal-teacher communication (mean = 3.20, SD = 0.59). This is followed by the teacher job satisfaction (mean = 2.93, SD = 0.27. The lowest mean score is on the perceived principal support (mean = 2.84, SD = 0.27). Therefore, we can conclude that the three key variables are at average level. However, all the key variables achieved mean scores of more than 2.5, which can be considered as moderate high level in practice.

Table 1: Mean and Standard Deviation of Key Variables

Key Variables	N	Mean	Standard Deviation
Teacher job satisfaction	300	2.93	0.27
Perceived principal support	300	2.84	0.27
Principal-teacher communication	300	3.20	0.59

The Relationship between the Perceived Principal Support, the Principal-teacher Communication and the Teacher Job Satisfaction

The Pearson-Product Moment correlation analysis was used to explore the relationship between teachers' perceptions towards the level of perceived principal support, principal-teacher communication and the level of teacher job satisfaction. Table 2 shows a summary of the correlations between the level of perceived principal support, principal-teacher communication and teacher job satisfaction. All the relationships were found to be significant and positive at a significant level of 0.01 accept the relationship between perceived

principal support and principal-teacher communication which has negative relationship. However findings showed that there are moderate weak relationships.

Based on Table 2, the principal-teacher communication has the stronger effect (r = 0.493, p < 0.01) compared to the perceived principal support (r = 0.386, p < 0.01) on the level of teacher job satisfaction. However the perceived principal support was found to have not only weak but negative correlation to the level of principal-teacher communication (r = -0.251, p < 0.01). In other words, the teachers' perceived that the higher the principal-teacher communication and principal support in practice, the higher would be their level of job satisfaction. The teachers' perception towards the perceived principal support was found to be weak and negatively correlated to the principal-teacher communication. This meant that the higher the perceived principal support, the lower the principal-teacher communication.

Table 2: Correlation between Perceived Principal Support, Principal-Teacher Communication and Teacher Job Satisfaction

Perceived Principal Support	N	r value	p
Principal-Teacher Communication	300	-0.251**	.000
Teacher Job Satisfaction	300	0.386**	.000
Principal-Teacher Communication			
Teacher Job Satisfaction	300	0.493**	.000

**Correlation is significant at the 0.01 level (2 – tailed).

The Contribution of the Teacher Leadership Dimension towards the Level of School Effectiveness
Multiple regression stepwise method was used to predict the influence of the perceived principal support and principal-teacher communication towards the level of teacher job satisfaction. With reference to Table 3, perceived principal support and two sub-scale of principal-teacher communication explain 48.7 percent of variance in teacher job satisfaction. Job relevant communication is the best predictor for teacher job satisfaction (β = 0.566, p<0.01) can explain 40.7 percent variance in teacher job satisfaction, followed by upward openness communication (β = 0.266, p<0,01) which can explain 6.3 percent variance on teacher job satisfaction. Finally the perceived principal support (β = 0.153, p<0.01) can explain 1.7 variance on teacher job satisfaction. There are three independent variables can fit the final model of teacher job satisfaction. When we use the stepwise method, each independent variable is put into the model, one by one in sequence as below: beginning with the level in practising job relevant communication, the level in practising upward openness communication and ending with the level in practising perceived principal support. As shown in Table 3, the adjusted R^2 value in final model was 0.487.

Table 3: Predictors of Teacher Job Satisfaction

Variables	B	B	R^2	Adjusted R^2	R^2 changed	t	Sig.
(Constant)	1.330					13.728	
Job relevant communication	.355	.566	.409	.407		12.203	.000
Upward openness communication	.103	.266	.474	.470	.063	6.370	.000
Perceived principal support	.065	.153	.493	.487	.017	3.298	.001

** Significant at the 0.01 level (2 – tailed).

Coefficient for the final model based on stepwise method reported as below:
$\hat{Y}_i$ = 1.330 + 0.355 X$_1$ + 0.103 X$_2$ +0.065 X$_3$
$\hat{Y}_i$ = Level of teacher job satisfaction
X_1 = Level in practising job relevant communication
X_2 = Level in practising upward openness communication
X_3 = Level in practising perceived principal support

DISCUSSION
Findings showed that the Xi'an key high school teachers has an average level of job satisfaction (mean score = 2.93). This implied that generally the teachers are satisfied with the working environment such as physical condition of the school, rules and regulation, supervision, salary and interpersonal relationship among co-worker. Psychological aspect referred as intrinsic motivation include recognition of their effort and achievement, career advancement opportunities and personel satisfaction seem to be attributes that teachers

value, this will lead to greater job satisfaction. This finding is further strengthen the report by Lewis and Michael (1977).

According to the finding, showed that perceived principal support in Xi'an key high schools is at average level (mean score = 2.84). This finding means the Xi'an high school teachers believe that the school principal values their contributions and cares about their well-beings, and school principals play a key role to support teachers' socio-emotional needs, such as respect and caring, being regarded highly by the school principal helps to meet teachers' need for approval, esteem and affiliation. Such perceived school principal support would increase teachers' felt obligation to help the school reach its objectives, their effective commitment to the school and that improved performance would be rewarded.

Although the result showed a moderate level of principal-teacher communication (mean score = 3.20), but it has higher mean score compared to the two variables above. Researchers can conclude by using Cheney's (1983) view that principal-teacher communication help each others to identify with their schools by transmitting messages conveying the goals values and achievements of the schools and by providing information in the form of guidelines for individual and collective action.

The research finding shows that there is a positive, significant but moderate weak relationship between perceived principal support and teacher job satisfaction (r = 0.386, p<0.01). This result indicate that teachers need school principal to concern and to care about them and to recognize their contribution to the school. It is also an evidence that teachers need support from their principal, this can make them satisfied with their job. However, the finding does not concurrent with Eisenberger et al's finding (1997). Eisenberger et al.'s finding (1997) showed that there are strong but negative relationship between perceived principal support and the teacher job satisfaction. This is because the employer does not have the resources to prevent unfavourable treatment such as poor economic conditions. This is something that contrast with what is happening in Xi'an key high schools which have good economic conditions and comfortable working environment. Therefore the same situations do not occur in this study.

The result indicate that the principal-teacher communication does correlate moderately with teacher job satisfaction (r = 0.493, p<0.01). This result is in line with the research findings reported by Haughey and Murphy (1983), Leiter (1988), Hurlbert (1991) and Ducharme and Martin (2000), but is contradictory with the results from Goris et al. (2000) and Goris et al. (2002). The results from Goris et al. (2000) indicated that the communication direction dimensions may increase work outcomes positively up to a point. After that point, further communication saturation may decrease performance and satisfaction. In addition, Goris et al. (2002) indicated that communication overload and communication under-load may inhibit satisfaction with communication. This inhibition might have negative consequence in both job performance and job satisfaction. However the same matter does not happen in China because communication in China school environment is always deficiency.

The negative significant but weak relationship between perceived principal support and principal-teacher communication (r = -0.251, p<0.01) is contradictory with the results from Allen (1995). School as a special working environment, communication is considered as a part of job, communication in schools may take a number of forms, including organized meetings, informal chats, notice-boards, memos and handbooks (Eden, 2001). If teachers get high level of perceived principal support, it can motivate their willing to work and privates with their school principals, these may decrease the informal communication between school principal and teachers.

A regression analysis shows there are three significant predictor for teacher job satisfaction, namely job relevant communication (β = 0.566, p<0.01), upward openness communication (β = 0.266, p<0.01) and perceived principal support (β = 0.153, p<0.01). The result shows that teachers need their school principal values their contributions and care about their well-beings, and further need communication with their principal in aspects of job relevant communication and upward openness communication. The result is consistent with the study by Goris (2004) which showed that satisfaction with communication may have a significant, predicting influence on both job performance and job satisfaction. Furthermore, the result also in line with Randall et al. (1999) that indicated perceived organizational support can predict job satisfaction.

CONCLUSION

The findings of this study indicated that, the perceived principal support and principal-teacher communication have an impact on teachers' job satisfaction among key high schools in Xi'an. For a school to be effective the relationship between school principal and school teachers should be given full attention, this can produce better school performance and be able to facing future's challenges. The importance of relationship between school principal and school teacher's should be emphasized, if the relationship is not given good care, a dominoes effect would take place and could affect the effectiveness of the school. Making

teacher more satisfied with their working would most probably making them prefer to remain in that particular school and contribute significantly towards the goals of the school.

Abstract: School principals in Spain have had few attributions allowing them to perform educational leadership in Secondary schools. However, significant changes are beginning to occur in the way school management takes place in Spain. These changes are already reflected in new regulatory legislations in a transition from a bureaucratic model to a pedagogical orientation designed to improve learning and results in the schools. This paper discusses the progressive convergence of our legislation and educational policy with with international guidelines of educational leadership. We review current studies and research into the tensions and dilemmas of school management in Spain, as part of a research project that we conducted about educational leadership in secondary schools.

Keywords: schools principals, educational leadership, Spain, school autonomy, secondary schools

INTRODUCTION

School heads in Spain have had few attributions allowing them to perform educational leadership in Secondary schools. However, significant changes are beginning to occur in the way school management takes place in Spain. These changes are already reflected in new regulatory legislations in a transition from a bureaucratic model to a pedagogical orientation designed to improve learning and results in the schools (Spanish Ministry of Education, 2007).

Spain has been, together with Portugal, the only European Union country where where school principals is a teacher at the school (with at least five years teaching experience), chosen by the School Council (teachers, parents and students). At the end of the period as head (four years, renewable), he or she returns to teaching. This system of being chosen by one's colleagues (together with parents and students) has its origins in the end of the Franco dictatorship, when there was a demand for a "democratic running of the schools", and where the organs of school management would be chosen by the school community. As we mentioned in a previous paper (Bolívar & Moreno, 2006: 19), "while this unique feature of the Spanish system entails many promises in terms of deep democracy and, equally important, the potential legitimacy of change promoted by school leaders, the truth seems to be somewhat less romantic".

School directive teams in Spain up until now have had little chance of exercising educational leadership, being limited in the majority of cases to administrative tasks within the existing organizational structures. A critical issue in the management and organization of the schools is what the head can and cannot do to improve the instructional work of the teacher in the classroom and, consequently, the students' learning. It is necessary to balance the principle of participation with the demands of professionalization, while ensuring the most appropriate professionals for the position of headmaster. In any case, the problem is not so much that the director is chosen by the teachers, but rather the way in which the organization where he or she works is structured. The principals and teachers operate in a certain *context*, which greatly conditions what they can do and- at times- traps them. In this context, beyond the individual players, the organizational structure seriously limits their role, making their condition precarious.

Administrative-bureaucratic model of school leadership, inherited in Spain, presented in late modernity, serious deficits to stimulate the schools. Instead, you should consider what are the tasks and responsibilities that should have principals in our schools and, according to them, to promote the necessary changes in the organizational structure of the school's new educational policy, as does the Act on Education or the new Education Act of Cataluña (Catalonia, 2009), talk about the role of "educational leadership" and "leadership" of the management teams. This transition from a bureaucratic model to a pedagogical direction can be seen, as discussed later in the new law (Decree 155/2010 of Catalonia on the direction of schools, the new organic regulations of Andalusia).

SCHOOL PRINCIPALS IN SPAIN

School principalship in Spain, particularly in secondary schools, has deep historical roots in a corporative model – where the principal is elected among and by the teachers – instead of being a professional figure (Viñao, 2005). Only during the central years of the dictatorship (1945-1970) was there a professional body of school principals, chosen among teachers via public concourse. After the General Education Law of 1970, the principalship is conceived as participatory and not professional. School principals were then chosen by the provincial education authorities among a shortlist of three candidates presented by the teaching staff of each school. Yet, the principal was seen just as a governmental representative, if not as an *agent*. Not surprisingly, after the fall of the dictatorship, there was a huge demand for a fully democratic model of school governance and management. Right after the fall of the dictatorships in both countries in the mid 70´s, Portugal and Spain experienced a growing social demand for a more democratic model of school governance, where principals should be elected directly by the members of the school community. The *Right to Education Act* (1985) regulated the participation of the school community in school management (through the creation of School Council) and the direct election of the school principal. It established a temporary, non-professional, participatory and collegial model of principalship, departing sharply from the prevailing model in OECD countries, which is permanent and professional.

Despite its democratic legitimacy, the figure of the school principal in Spain would remain weak in that decision making and control are placed in the School Council. The participatory or democratic model de facto became corporative, as the principal is overtly dependent on the colleagues who elected him or her (teachers are the majority in the School Council). At the same time, s/he continues to be the representative of the education administration in charge of implementing and enforcing its regulations. This double function is a continuous source of trouble (Coronel & Fernández, 2002). Since the principal is elected by his/her equals, and will eventually have to re-enter teaching, s/he is forced to transact every decision with the teaching staff of the school. On a related account, School Councils have hardly lived up to the expectations, partly because parents have very low levels of participation in electing their representatives (a modest 15 percent), partly due to the ritualistic and formal makeup of these bodies, reflected both in the contents and the procedures of participation (Fernández Enguita, 1993, 2007; San Fabián, 1997).

The unsolved problem of school leadership in Spain is known as the "*cuestión directiva*", reflecting widespread discontent in the education sector with the shortcomings and the unfeasibility of a participatory model which seems impossible to consolidate (Gairín, 1998; Murillo, Barrio & Pérez-Albo, 1999). The deterioration of the model was evident when, already at the beginning of the 90´s, there were no candidates willing to run for the principalship in roughly 50 percent of the schools in the country. In these cases, principals were appointed by provincial education authorities, with a provisional mandate of just one year, until there was a candidate ready to be elected. This shortage of candidates to become school principal pointed to structural problems of the participatory model of school leadership. A supposedly *political* model of school leadership was becoming, in practice, a *corporate* model. Many different causes would appear to account for it: the double function of the school principal –representative of the education administration and of the school community– which triggers tensions and role conflicts, the lack of autonomy for decision making, the overload of bureaucratic tasks, the absence of support to perform leadership the leadership responsibilities, etc. A real crisis of the principalship followed, combined with declining rates of participation in School Councils by teachers, parents and students, all of have led to a progressive weakening of the leadership function in Spanish schools.

The successive problems produced by this elective model are motivating a change to a more professionalized management and a greater capacity for pedagogical leadership. In this crisis, various causes have converged: in a high percentage of cases (40%), the election mechanisms have not worked due to lack or shortage of candidates, with directors having to be assigned obligatorily by the Administration in these cases; the unavoidable transaction mechanisms with the co-workers that elected the head make it impossible for him or her to engage in leadership for improvement in the long run; finally, this system has not led to the exercise of a distributed, shared or democratic leadership in a professional community of learning. This corporative collegiality interferes with the practice of a pedagogical leadership (Bolívar & Moreno, 2006).

Bolivar (2006), based on research conducted for the National Institute for Quality and Evaluation, designated as the model election by the School Board, established in 1985, has not adequately addressed the management of schools, among other things the absence of candidates and non-professional, advocating a pedagogical leadership. Surprisingly, that education policy has remained in oblivion for a long time professionals with such a decisive role on the performance results (Beltrán, Bolívar *et al.*, 2004). As they say in a situation similar Blase *et al.* (2010: xxiv), "this is particularly discouraging in light of strong evidence

that effective instructional leadership by the school principal is a key within-school factor in promoting school improvement and is second only to teaching in contributing to student learning".

While the democratically elected principal was expected to enjoy high levels of legitimacy as a school leader in a political and educational context emphasizing democratic values, that is certainly not the case in a neoliberal environment, where parents are no longer citizens involved in the education of their children but rather clients demanding more quality and improved outcomes.

A good number of proposals to professionalize school principals in Spain have been made since the early 90´s. (Estruch, 2002; Batanaz & Alvarez, 2004). Yet such *professional turn* can be understood in at least two different ways: a) as capacity building of teachers to become school leaders, or b) as a function radically different from teaching, which requires specific training and recruitment procedures (opening the possibility of having principals with no teaching background). In Spain, probably due to its historical tradition in education, the prevailing sentiment is that instead of professionalizing school managers, we need to qualify and upgrade teachers´ skills in management.

Despite some important differences across regions, the proportion of schools with teachers willing to run as candidates to become principals increased by 20 percent (from 40-50 percent to 60-70 percent). The enhanced authority and responsibilities conferred to the principal by the new Act, the loss of power of the School Council (which becomes a consultative body), increased economic incentives, and a more clear-cut managerial job description may account for this change. However, on the one hand, still more than one third of the schools did not have teachers ready to run as candidates. On the other, and even more importantly, wide sectors of the teaching profession (in particular the teacher unions) and some parent associations were clearly against doing away with a democratic election of the school principal by the school community.

As a consequence, Consequently, the socialist government, through a new Act on Education (LOE, 2006) – published in May 2006– has tried to balance the professional approach of principalship with the active participation of the community in the (s)election process. While on one hand, it preserves the participatory model, otherwise the education administration authorities being in charge of accrediting their professional competence and providing targeted training. Therefore, the new regulation in Spain *Organic Education Act*, passed in 2006) has changed the election system to one of "selection", in which certain training and experience requisites are demanded of the possible candidates, and representatives of the educational Administration intervene in their selection. The candidates for headmaster must present, in addition to their curriculum vitae, a *management project* that includes objectives, action lines and improvement standards. Thus, we want to find a balance between the role of the school and the intervention of the Administration, in order to ensure their professional competence. The practice of principal to improve the quality of education, will undergo an evaluation process to identify problems and improve action. Following the positive evaluation of his administration, the director may consolidate a financial supplement proportional to the years of practice.

Currently, it is claimed, first, moving from a model "collegiate" in educational leadership, as the logic collegial corporate nature not possible (in some cases prevent) the practice of educational leadership. On the other hand, in a line of increasing professionalism, have to take steps for non-corporate choice of director for the Teaching Staff. It is true that these steps have to be progressive, since the great hindrance is established school culture, which prevents the director to exercise educational leadership role, able to promote improvement. It is also clear that one can not remain the exception in the world in the way of establishing the school headmaster. Current literature and most relevant experience should have the desired reflected in the legislative guidance.

In the current conditions, a role limited to the bureaucratic management of the schools is becoming insufficient. The school's main responsibility is precisely to guarantee the educational success of all its students. The outcome cannot completely depend on what each teacher, with more or less commitment, decides to do in the classroom. Therefore, the school principal inevitably has to participate in improving the teaching and learning offered by the school. This action is currently the topic of some debate in Spain, but in the experiences and international literature (Robinson et al., 2009; Louis, Leithwood et al., 2010), it is becoming more and more obvious: if teachers are the key to the improvement, then principals have to create an appropriate climate in which the teachers can improve, supervising the outcome and encouraging progress. However, as we explain below, in Spain we have a set of challenges pending in going from the current management model to one of leadership for learning (Bolívar, 2006).

A BUREAUCRATIC PRINCIPALSHIP TO EDUCATIONAL LEADERSHIP

Spain in the last two decades has experienced a spectacular development in education (level of coverage, extending years of schooling, changes in curriculum, remedial education programs, substantial increase in funding, better teacher salaries, etc.).. However, this has not translated, significantly, an improvement of learning (PISA results and other accountability). Of course, there are many factors influencing this improvement, including teacher training and quality of instructional processes developed. But as we advocate in this paper, the leadership of principalhip has a leading strategic role.

In fact, between the "logic of confidence" and voluntarism teachers, little could be done to go beyond the contingency of teachers available to each school. As stated Elmore (2000: 6-7), "because the administrative structure of schools exists to buffer the instructional core from disruptions and improvements, and because teaching is isolated work, instructional improvements occur most frequently as a consequence of purely voluntary acts among consenting adults". This pending change this situation, which can be illuminated by research results that show, providing courses of action within the powers and competencies that school leaders must have their training, their work centers according to priorities and modes of assessment . Demand is thus a convergence of educational policy with the evidence that research at the international level (Leithwood, Day *et al.,* 2006; Louis, Leithwood *et al.,* 2010), has revealed.

The principalship has been traditionally more focused on the administrative management of the school, moreover, in their capacity as *primum inter pares*, has little capacity to intervene in pedagogy. In Spain, the directors have no real ability and autonomy to manage their school pedagogically also has not received adequate pedagogical training to exercise leadership in your organization (Bolívar, 2004, 2010a). As noted above it also seems clear that the model of election of directors by their counterparts in Spain poses serious difficulties for teaching and educational leadership. As mentioned earlier, the TALIS (OECD, 2008) draws an address in Spain with little capacity to improve teaching and learning processes (see Table p. 197).

Today, influenced by current trends, which they consider a priority of pedagogical leadership role (Pont et al., 2008), is starting *a gradual convergence of educational policy to educational leadership*. These changes, reflected in new legislation, points to a transition from a bureaucratic model to an educational direction aimed at improving learning and school performance.

In this regard the current Education Act (LOE, 2006) introduces (art. 132) as a novelty, between the powers of the principalship, "to exercise educational leadership". Similarly, by limiting ourselves to those approved and published, the Education Act of Andalusia reaffirms the role of "educational leadership" (art. 132.1). For his part, the Education Act of Cataluña (2009) specifies that have functions of "pedagogical leadership" (art. 142), particularly in the exercise of autonomy in parallel with the educational authorities should encourage and support "the leadership skills of professionals in the organization and management of schools" (art. 100). In addition to the educational leadership that speaks the Act on Education (LOE, 2006), in Catalonia the "Decree on the principalship of public schools" (Catalonia, 2010a and 2010b) provides new ways to understand management schools: "the school leadership, acquires a global leadership role in the action of public schools", says.

Schools autonomy and educational leadership

The report *"School autonomy in Europe. Policies and measures"* (Eurydice, 2007), which examines 30 European countries shows that the countries of northern Europe give more autonomy to schools to the south and are also the best performing in international assessments such as PISA. Spain, with Portugal and Greece, is among those who have more limited autonomy. In turn, the report TALIS OECD (2009: 197) shows a principal in Spain with little capacity to improve teaching and learning processes. According to the perception of educators, gets the lowest score in educational leadership and managerial leadership, significantly below the average. Without a strong educational leadership there can be no school autonomy, so understood, the OECD itself (Pont, Nusch & Moorman, 2008). For this, as also said development of the OECD report (Stoll & Temperley, 2009),

> "School leaders can only have an impact on student outcomes if they have sufficient autonomy to make important decisions about the curriculum and teacher recruitment and development and if their major areas of responsibility are focused on improving student learning. Countries are increasingly opting for decentralised decision making, and balancing this with greater centralisation of accountability regimes such as standardised testing." (p. 13).

Is this part, also demands increased autonomy of schools in Spain are continuing and increasing. There is a general trend of progressively increasing decentralization and autonomy, linked with accountability - within

a "new public management". The latest Education Act of 2006 opens doors for performance, and, subsequently, some educational laws of the autonomous communities (Andalucía, Cantabria, Catalonia, Castilla-La Mancha) have finalized some ways to go. The directors are acquiring greater powers to intervene in the management and quality of education.

The education policy has to enable each school to "build" their autonomy through their own projects, stimulating endogenous dynamics of each school through *contract-programme*, together with the necessary external support. Thus, once concrete proposals for action in the school educational project in a sort of "contract-program" of autonomy, negotiated and agreed with the Education Authority. This proposed "contract-program" is present in some countries (Portugal, France), the Law of Education of Catalonia (Catalonia, 2009), developed largely in the Decree of autonomy of schools (Catalonia, 2010a) and collected by the Ministry of Education in "Action Plan 2010-2011", within the General Objective 7, which states as a 5:

> "Promote *contracts-program* to several years, including education authorities and schools, with the appropriate funding, human and material resources needed and the flexibility in their management, as well as technical support and teacher training, to achieve, particular, increasing the academic success of students".

They agreement, as shared responsibility, is at the heart of the program increased student achievement. In exchange for the resources provided by the Administration, the school will implement the agreed action plan and accountability to the school community and educational administration. The possible renewal of the mutual agreement remains subject to the outcome of the evaluation. Catalonia was the region (in Spain "Autonomous community") that until now has gone further in setting the principalship and educational leadership. The Education Act of Catalonia (2009) entrusts the principalship (Article 142.3) "educational leadership and school learning community", always understood aimed at improving educational outcomes. Make decisions in the curriculum by principalship, says the Decree of Autonomy (Catalonia, 2010a), is, from the curriculum framework established, the possibility of actively intervening in the curriculum and school management modes so as to allow own performance to ensure the greatest educational success of their students.

In turn, the autonomy is linked to improved results. Therefore, Article 5 states that each school should establish indicators of achievement related to students' academic performance. These standards are the benchmark for evaluation of the school every four years, coinciding with the completion of term of headmaster, at which have to be revised. They are also the reference point of self-evaluation as an element that promotes continuous improvement. Thus, the Catalan Decree of Autonomy states that "schools may establish their own educational projects that require time organizing material different from that stated in general terms, with the ultimate goal of improving students'academic performance" (art. 17.1) .

Principalships can manage aspects of personnel selection to find a faculty profile that suits the school's educational project. Also you can select the teachers, and have the ability to impose penalties. Principals in Catalonia have responsibilities as chief of staff, so they can decide how many teachers they need according to their educational programs. According to Article 8 of Decree of Directors (Catalonia, 2010b), the principal will propose budget allocations and the teaching staff, always adjusting to the school's educational project.

Given that the circumstances (autonomy, assigning responsibility for the results) make it necessary to follow this path, the situation is, therefore, one of no return. If the teaching staff is the key to this improvement, the directors must create the conditions and the context in which the teachers can improve their professional activity. Therefore, a critical point regarding the management and organization of centres in Spain is what the head does or can do to improve the teaching performance of the staff in their classrooms and, as a result, the students' learning (Bolívar & Moreno, 2006). If schools should ensure that all students key competencies, the headteacher is to make it happen. Therefore, the headteacher can not be limited to management and organizational tasks of human resources, should look more to everything that can encourage improvements in education. It is however difficult in the current structures to exercise educational leadership.

An educational leadership

In this situation, we can discuss what the headmaster in Spain can and cannot do to improve the instructional efforts of the teacher in his or her classroom and, as a result, the students' learning. Of course, it is necessary to change from a "transactional" model where the schools choose the principal according to their interests, which are sometimes corporative, to a "transformational" model (Leithwood, Jantzi & Steinbach, 1999). The

dependence of the voters, as in politics, makes them less likely to be able to move ahead in a proactive and transformational way. It is necessary to break these links of dependence (Fullan, 1998), and implement other external regulations, in order for educational change to take place.

Many things are important in the practice of school leadership, but some of them are not essential for the improvement of teaching and learning. Therefore, educational leadership action should be directed to create contexts for learning, focusing on clear expectations of achievement levels. The structures of public schools rather isolated and idiosyncratic values favoring individual learning at the expense of the collective. Beyond that permit structures, there are managers who manage staff engage in a collective project exciting, providing a good education. While educational research should investigate what factors and dimensions involved in these good practices in case they might be transferred or generalized to other contexts, also should care system, beyond the contingent factors, how to make every school a good school, more so for those who are in difficult or low yields.

Influenced by current tendencies which consider the role of educational leadership a priority, we now have a progressive convergence of our legislation and educational policy with these orientations. In this regard, the current Organic Education Law (LOE) introduces (art. 132) as a novelty among the competencies of the director "exercising a *pedagogical leadership*, promoting educational innovation and fostering plans to achieve the objectives of the educational project of the centre". In a similar way, the legislation of the Regions and Autonomous Communities (Andalusia, Catalonia), which have considerable autonomy, limiting ourselves to those that have been passed and published, specify- and broaden- the exercise of pedagogical leadership. Thus, the "Decree on the autonomy of schools" of Cataluña points out that "the schools' management acquires a role of global leadership of the action of the public centres".

However, it is difficult to exercise educational leadership within the current structures. The schools as organizations are "weakly connected", with each teacher functioning independently in his or her classroom, so that the directors have few or no possibilities of supervising what goes on in the classroom and –therefore- of practicing "educational leadership". The inviolability of the teachers' choices and actions in class about what they teach and how they teach it impedes any educational supervision by the direction. The atomization and fragmentation of the teaching, as well as the habitual individualism, effectively hinder both collaboration and joint evaluation of what is planned on a general level and in specific practice in the classroom. When the organization is weakly articulated and the individual teaching practices depend on the will of each teacher and the "logic of trust", talking about pedagogical leadership becomes barely significant, given that the institutional structure, in principle, restricts it. There is teacher resistance to any type of supervision and orientation of their teaching, based on a corporativism and individualism that translate into a lack of intervention by management. A long tradition ingrained in the school culture (especially in Secondary) creates a situation where the head of the public school does not know what takes place in the classrooms, and the information he or she might have usually arrives by indirect routes. Given that isolation is one of the main enemies of improvement, a pedagogical management should contribute to creating a shared vision of the school.

Leadership for learning

Research on school leadership in Spain (Murillo, Barrio & Perez-Albo, 1999; Gairín & Villa, 1999; Gago, 2006) has tried various organizational variables and dimensions research (tasks and duties, satisfaction and problems, training, leadership, choice, effectiveness, change and gender). For over a decade has focused especially on the "cuestión directiva" (directive question), as the problem of combining choice by the school community and professionalism. While in some sense it could be is to enhance the sense of direction in a democratic and participatory school (Santos Guerra & Antúnez, 2009); in practice, these expectations of a culture for participation have not been made. However, overall, has been less than enthusiastic about the priority issue at the international level: the learning-centered leadership. In research on instructional leadership in Spain (monitor and guide the education, coordination of curriculum, student tracking) concluded Gago (2006) that this was more a theoretical than a real practice. In the analysis of common tasks of principals concluded Gimeno *et al.* (1995: 199): "principals not primarily focused their energies on educational leadership roles within the teams of teachers. Neither is configured his post today to exercise that function or assume it as relevant towards others".

This bureaucratic model of the school management presents serious limitations to acting to improve the results of the school. The reality is that when the management is limited merely to doing administrative paperwork, the responsibility for the students' learning becomes diluted; when the focus is on a leadership for learning, this responsibility becomes essential. Therefore, a future agenda in improving management's performance is to understand it as a *leadership for learning*, which links the administration's practice with

the students' learning and the results of the school. If, as research has shown (Robinson *et al.*, 2009; Louis, Leithwood *et al.*, 2010), the educational leadership is the second most relevant internal factor in the school with regard to learning achievements, after the activity of the teaching staff, a change is needed in the competencies of the directors, so that their effects on improving learning outcomes in their respective schools can be increased.

In the first place, the primary objective of 21st century educational policies is to guarantee that the students receive the necessary preparation to enable, without risk of exclusion, their integration and active participation in public life. Leadership in education exists, without doubt, to make this happen. We need, then, the best management teams that can carry out educational leadership. Making the position of school director an attractive profession and developing the competencies for an effective leadership are two lines of action recommended by the OCDE (2008) in its well-known report (*Improving School Leadership*). Attracting the best candidates should be encouraged through compensation, professional careers and training. Secondly, there must be *adequate initial and in-service training*. School leaders need specific preparation to respond to the additional functions and responsibilities, especially regarding strategies to improve school results.

If the school management has been based on a set of regularities that govern the organization of the schools, the new administration is demanding a change in role that would not be possible without an organizational restructuring. Thus, the need arises for a type of school leadership that produces, in a "transformational" way, the development of the school as an organization. Making an educational leadership possible (pedagogical or instructional) requires, then, changes in the current organizational structure. The Secondary schools are currently organized in a culture of isolated departments that favour idiosyncratic values and individualistic learning, so that the action of the educational leadership should be directed toward creating contexts for collaborative learning, which means redesigning the organization in ways that make the desired actions possible.

The heads of Secondary schools must create settings and make spaces and times available that facilitate and support the learning of the teachers, the organization and, finally, the students. Obviously, if the main element is the students' learning, those structures should be promoted that make it possible to improve the level of learning in the classroom, supporting and stimulating the work of the teacher in class (Robinson *et al.*, 2009). In this measure, the management teams focus their action on *redesigning the work contexts* and professional relationships, and they are called on to be "pedagogical leaders in the school". The creation of a culture focused on the students' learning requires fostering cooperation and cohesion among the teachers and a sense of a job well done, while developing understanding and visions of what they want to achieve.

44- A Research Project on Learning-Centered Leadership and its Impact on Improving Academic Achievement in Spain

Antonio Bolívar[1], Jesús Domingo[2], and Katia Caballero[3]

Faculty of Education Sciences, University of Granada, Spain
[1]abolivar@ugr.es, [2] jdomingo@ugr.es, [3] kballero@ugr.es

Abstract: This research project, under the new guidelines reflected in the international literature, intends to research how instructional leadership is an important factor in improving outcomes in Secondary Schools. So far, Headteacher has had little capacity to influence the improvement of teaching practice; however, new regional legislative guidance, from the LOE (new mode of selection, powers and competence), enhance the educational leadership. Particularly we research, first, how secondary schools whose teams show high educational leadership *best performer*. It is intended, first, analyze the *factors and variables* related to instructional leadership have an impact on student learning; and -other-what *best distributed leadership practices* in secondary schools contribute to improving education. It uses a quantitative methodology through survey to managers, teachers and students. From the results, it articulates a multi-case study methodology to combine data from interviews, observations and previous results from the survey.

Keywords: leadership for learning, effects of leadership, academic achievement of students, professional development.

FRAMEWORK AND RELATED RESEARCH

"Leadership" is the capacity to influence other people, but not based on power or formal authority. Providing direction around common goals in an organization and exerting influence so that the staff will rally round these goals are two of the defining functions of school leadership. In the words of Louis, Leitwood *et al.* (2010), "leadership is all about organizational improvement; more specifically, it is about establishing agreed-upon and worthwhile directions for the organization in question, and doing whatever it takes to prod and support people to move in those directions" (pp. 9-10). When these efforts are directed toward improving students' learning, we are talking about *educational* or *pedagogical leadership*.

A critical issue in the organization of schools is, then, what the principal does or can do to improve teachers' performance in the classroom and, consequently, pupils' learning. For these reasons, the educational leadership or pedagogical management of schools is becoming, at an international level, a *first-order factor* in the improvement of education, at the same time that it appears as a priority on educational policy agendas. In this study, we propose, on the one hand, to analyze the perspectives suggested by recent research on new leadership orientations and, on the other, to apply them in an investigation of the Spanish reality, so that leadership teams would be able to perform this educational leadership.

The conditions for exercising leadership in Spain are changing significantly. These changes are beginning to be observed in the legislative regulations, moving from a bureaucratic model toward one of educational leadership focused on the improvement of learning and outcomes in the school, in accordance with the orientations reflected in the international literature. In this situation, as a relevant report by the OECD describes, "we need to contrast these trends with the current practice and shape of school leadership in OECD countries. In many countries there is growing concern that the role of principal designed for the needs of a different time may not be appropriate to deal with the leadership challenges schools are facing in the 21st century" (Pont *et al.*, 2008: 27). Therefore, we consider this research to be especially opportune.

The objective of our research project falls into what we believe is the next agenda in improving school management practices, *a leadership for learning*, which is linked to students' learning and the school's results as a whole (Macbeath & Nempster, 2009). This line of research offers a strong relevant theoretical framework for investigating educational leadership practices (Day *et al*., 2011; Townsend & Macbeath, 2011). Recent studies on school efficacy and improvement have highlighted the role played by educational leadership in organizing good educational practices in schools, and in contributing to the improvement in learning outcomes. Research reviews produced in recent decades (Hallinger & Heck, 1998; Marzano *et al.*,

2005) point out that leadership teams can make a critical difference in the quality of schools and the pupils' education.

The core of learning-centred leadership's action is the quality of teaching offered and the learning results achieved by the students. The other dimensions of its daily activity serve to advance this priority goal of the school's mission. Nevertheless, as some studies have shown (Leithwood, Louis *et al.*, 2004; Marzano *et al*., 2005), the impact on learning improvement occurs *indirectly*, through its influence on the organizational conditions of the school and the teaching quality, depending on the practices developed, how leadership is distributed, and the creation of a culture focused on student learning. This capacity grows in educational policy contexts where schools have greater autonomy and, consequently, greater responsibility for the academic results (Stoll & Temperley, 2009).

The OECD is carrying out a broad programme (*Improving School Leadership*) for the improvement of school leadership in its member countries (Pont et al., 2008). This programme defines four major lines of action: *(re)defining school leadership responsibilities, distributing school leadership, developing skills for effective school leadership, and making school leadership an attractive profession*. The successful effects of leadership on students' learning will depend greatly on both the practices developed, such as whether leadership is distributed or shared, and the decisions made about the dimensions to which the school should dedicate time and attention. In an excellent study, Leithwood, Day *et al.* (2006) described four types of leadership practices that impact students' learning: *Building vision and setting directions, understanding and 'developing people', restructuring the organization and redesigning roles and responsibilities, managing and supporting the teaching and learning programme.* Obviously, if the main element is the students' learning, those structures that make improvement possible at the classroom level must be redesigned in such a way that they support and stimulate teachers' efforts in the classroom (Robinson *et al*., 2009). With this measure, leadership teams direct their actions towards *redesigning the work contexts* and professional relations, which means they are called upon to be "the school's educational leaders" (Leithwood, 2009).

In spite of the aforementioned importance of the school leadership in improving teaching, we do not intend to attribute to the administration causal factors that do not correspond to it. In this sense, as pointed out in Elmore (2000), it is necessary to *de-romanticize* leadership and not project on it what should be good qualities of organizational functioning. Instead, there should be an emphasis on a *distributed leadership* among all the members (Harris, 2008), which would contribute to engaging the staff in the improvement. Leadership- apart from ingenuous proposals- is not the solution to every problem, only some of them. In a parallel way, it is important to focus the attention, on the one hand, on potentiating *teacher leadership* (Lieberman & Miller, 2004; Harris, 2004) and, on the other, on schools as *professional communities of effective learning* (Stoll & Louis, 2007). The idea is to generate a robust school culture where all agents are involved (including the family and the community) in a process Kruse and Louis (2008) call the "intensification of leadership". Without creating a sense of community that values learning, leadership alone can accomplish very little.

INVESTIGATING THE EFFECTS OF LEADERSHIP: A COMPREHENSIVE FRAMEWORK

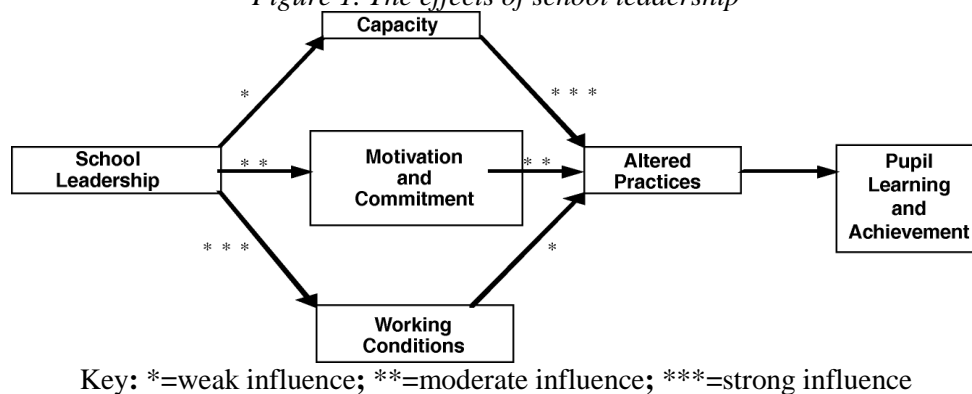
We need a comprehensive framework of different variables that can cause leaders' and principals' actions to have an impact on improving pupils' results. One of the most important studies carried out on the topic (Day *et al.*, 2008a) points out that the independent variables (leadership practices) are developed and emerge through the influence of antecedent variables. Likewise, successful leadership practices are related to a wide range of other variables. Some of them play a moderator role, increasing or diminishing the effects of leadership, while others link or mediate leadership practices with students' learning. Research advances on the effects of leadership imply, as these researchers maintain, recognizing the diverse groups of variables involved, as well as their mutual relationships.

Research has shown the effects of leadership on improving results, although these effects may be mediated by the teaching practices in the classroom (Waters *et al*., 2003; Leithwood & Jantzi, 2008; Robinson, 2007). These researchers conclude that, among all the internal factors of the school, after the teachers' work in the classroom, leadership is the *second factor* contributing to what students learn in school, explaining about 25% of all the school's effects. Furthermore, these effects are normally more relevant where and when they are most needed, that is, in those schools that find themselves in difficult circumstances or in disadvantageous situations.

A broad study carried out by some of the best investigators in education (Day, Sammons, & Hopkins, 2009) dealt with the *impact of leadership on pupils' results*. The authors found that students' outcomes (cognitive, affective, social behaviour) depend first, as a mediator variable, on teachers' working conditions, whose impact on learning is moderated by other variables, such as the family's cultural capital or the organizational

context. Any or all of these variables can be influenced by those who perform leadership roles, thus producing improvements in students' learning. The specific question is how to intervene in the professional teaching culture, professional development or work conditions of teachers in ways that lead to the desired objectives.

Figure 1. The effects of school leadership

Key: *=weak influence; **=moderate influence; ***=strong influence


As *Figure 1* shows, a key task for leadership, if it is to influence pupils' learning and achievement, is to improve teachers' performance (Leithwood, Harris & Hopkins, 2008), which depends on their motivation and commitment, capacity or competence, and working conditions. Although principals can influence the teaching competencies less directly, they can have a strong influence on the other variables (motivations and commitments, teachers' working conditions). The figure shows, in a simplified way, the strength of the relationships (low, moderate or high influence), according to the results of the study. When principals exercised this type of leadership, they had a greater influence on these intermediate teacher variables, which, in turn, conditioned the new teaching practices and, finally, the students' results. The figure also shows that teaching capacities have the greatest influence on the practices, although the principal's degree of intervention in them is less. This is a challenge that will have to be faced in the future. In the same way, the feeling of efficacy becomes a first-order variable.

According to Wahlstrom (2008), studies that link the exercise of leadership to students' academic achievement highlight four topics: (i) *the context* plays a first-order role in whether leadership practices have one effect or another; (ii) *the relationships are multi-dimensional, not lineal*, given that in reality a directional hierarchy of leader and followers does not work; (iii) the *beliefs system*, in the form of self-confidence or a feeling of efficacy, *is a key mediator* of the influence the leader can have in the teaching and learning; (iv) the *effects of leadership* on teaching and learning are *indirect*, given that they are not directly involved in the daily teaching practices in the classroom.

Nevertheless, the effects studied in the research refer to leadership in the Anglo-Saxon context, with quite different roles and capacities from those of the principal or leadership team in Spain. Therefore, it is necessary to appropriately adjust and contextualize these studies. With regard to the Ibero-American context, for example, in Chile a large team, promoted by the Centre for the Study of Policies and Practices in Education (CEPPE) together with the Chile Foundation, is carrying out a study on "Principal Leadership and Quality of Education in Chile", with a broad sample of primary schools in urban areas (Weinstein, Muñoz et al., 2010). In their case and ours, the main challenges in studying school leadership are the following:

> 1. *Quantifying* this phenomenon, in terms of its effect on school processes and outcomes, while rating the impact of the different ways of exercising leadership (Louis, Leithwood *et al.*, 2010);
> 2. *Qualifying* school leadership: basic characteristics, successful leadership practices, the way leaders exert their influence and predominant forms and styles; and
> 3. *Contextualizing* the analysis of leadership: taking into account specific characteristics of teachers, schools and educational systems (leadership as a dependent variable).

INVESTIGATING LEADERSHIP IN THE SPANISH CONTEXT: A RESEARCH PROJECT

We are beginning an I+D[104] Research Project in which we intend to investigate educational leadership as a first-order factor in improving academic achievement. Specifically, as the *initial hypotheses*, we have established the following:

> 1. Schools whose management teams show *a high level of leadership obtain better results*. This hypothesis leads us to employ a quantitative methodology, along with results from external evaluation tests. Other antecedent context variables will also be taken into account: the school's image, involvement of the families, and demands for schooling.
>
> 2. It is possible to identify a common repertoire of *good school leadership practices* that create a context for better work by teachers and, as a whole, by the entire educational establishment, shared by other members of the educational team, as a quality of the organization.
>
> 3. *Educational leadership* has a greater impact on improving education when it is broadly *distributed* and *shared*: teacher leadership and professional learning communities. The intention is to verify this hypothesis, specifically focusing on which guidelines and structures favour and contribute to a significant improvement in the educational activity of the school.

Thus, the aim is to generate educational knowledge that contributes to fostering educational leadership in educational institutions, focusing specifically on secondary schools. Our research is based on the idea that it is possible to find a set of successful actions by the school leadership that create a context where teachers can work better. On the other hand, beyond the leadership team, the objective is to show forms of distributed leadership, particularly through teacher leadership and professional learning communities. This objective first involves the use of a quantitative methodology through questionnaires presented to principals, teachers and students. Based on the results, a *multi-case-study methodology* is then articulated to combine data stemming from principal, leadership team and teacher interviews with observations of tasks and school culture, juxtaposed, in turn, with the prior results from the questionnaire and other data from external evaluations.

Objectives

There are two main objectives of this project: to verify to what degree and in what ways the leadership of the administrative teams impacts pupils' learning; and what good leadership practices in the High Schools, not limited to the administrative team, make a decided contribution to improving education. Within the aforementioned theoretical framework, the intention is to generate educational knowledge susceptible to fostering the necessary leadership practices for creating conditions and structures that produce a positive impact on students' learning. These objectives are broken down into the following:

1.- Analyze and determine which *factors and variables have an impact on school effectiveness* (academic achievement of the students) and, among them, especially the influence of the school administration in the High Schools.

2.- Define the repertoire of *good practices* successful principals use to influence, as a mediator, the learning outcomes, and the way principals modulate these practices and adjust them according to the situation or context. This objective is broken down and specified in:

3.- Given the indirect influence of leadership on academic achievements, another objective is to *describe and analyze how the leadership affects the motivations, skills and working conditions of the teachers, who, in turn, affect pupils' results*. In this objective, an attempt is made to enter the dimension of teaching practices and their relationship with leadership, such as the following:

4.- Examine in-depth and contrast the thesis that school leadership has a *much greater influence when it is widely distributed* among administrative teams, teaching staff, families and students. This objective attempts to verify the possible positive relationship between the increase in the distribution of leadership roles and responsibilities and the continued improvement of the pupils' results. At the same time, it implies analyzing the forms of distribution in each school, paying attention to a set of dimensions: forms of distribution according to the position in the organization; degree of coordination and interdependence; relationship

---

between the power and authority of each leader and the acceptance of the corresponding responsibilities; stimuli for the distribution of leadership. More broadly, the intention is to analyze the school culture of working together, planning meetings, leadership in each meeting, etc.

Methodological design

Current research on leadership and its effects has become methodologically broader and richer in the last few decades (Heck & Hallinger, 2005). Due to the complexity it has acquired, a wide range of research techniques is needed, suggesting the use of a *mixed methods* methodology combining quantitative and qualitative methods which support each other in obtaining a greater understanding of leadership effects. In a parallel study ("Vitae study") to which we referred above (Day *et al.,* 2009), Day, Sammons and Gu (2008b) justify the combination of quantitative and qualitative methodologies in that the "conceptual and methodological integration led to synergistic understandings that enabled the discovery and delineation of key findings that were both more enlightening and more robust than would have been the case if one method or another had dominated" (p. 331). Moreover, this combination is justified by the research objectives themselves: importing the results obtained from each school, the research tradition on school effectiveness has made substantial contributions to the collection and analysis of data from a quantitative point of view, but it has been justly criticized for not explaining how the processes developed, and the internal conditions of each school can affect these outcomes and explain the *value-added* provided (Sammons, 2007). A combination of quantitative and qualitative methods is also used by Louis, Leithwood *et al.,* (2010) in their study.

Thus, we first use a quantitative study, as objective 1 describes. We base our construction of the questionnaires on the school effectiveness research tradition, which has provided a basis for the consolidation of a model which includes *context variables*, like the characteristics of the school and the environment; and *baseline variables*, like family conditions, prior academic results, expectations of the student and the family, etc. Among the *process variables* are those related to the teaching activity in the school and the classroom, the role of the different strata of the school, especially the school principal and the departments, and the existence of common goals, coordination and a shared vision. Likewise, in this section we place all the variables that have to do with the teaching-learning of the student. In this regard, we have reviewed some of the most widely-used questionnaires (*Principal Instructional Management Rating Scale, Vanderbilt Assessment of Leadership in Education*). The quantitative data stem from questionnaires presented to three groups of relevant agents and actors in the educational process: Students, Teachers in the school, Administration.

Furthermore, in-depth interviews are being carried out of the participants selected in the *case study*, making it possible to investigate the main dimensions linked to improving results from the school leadership perspective. Given that leadership is always contextual and contingent, case studies can show which leadership practices have an effect on improvement. International research has shown that, even when there is a repertoire of successful practices performed by the majority of administrative leaders in schools (Robinson, 2007; Day *et al.*, 2009; Louis, Leithwood *et al.*, 2010), the context is a determining factor in the ability to put them into practice and in the form they take. Especially important are the values, strategies and competences of leadership, the moderating factors (cultural capital of students and families, organizational culture, context of the school), and the mediating factors (teaching-learning processes, teachers' commitment, etc.). It is also advisable for each participant to interview other colleagues who can provide their views of the ways leadership is practiced.

A *multi-case-study methodology* will be used to coordinate contextually sensitive data stemming from interviews with the principal, the administrative team and the teaching staff, together with observations of tasks and school culture, juxtaposed -in turn- with the prior results from the questionnaire and other data coming from external evaluations. Case studies provide the perceptions and ways of acting, along with an opportunity to discover the causes through "intuition, discovery and interpretation" (Merriam, 1988: 10), in so far as the social reality is constructed by the people involved in the situation. As described by Day, Sammons *et al.* (2008): "this mixed-methods approach was designed to enable a sufficient and appropriate range of data concerning leadership and leadership practices to be collected and analyzed so that a coherent, empirically derived and theoretically robust model of direct and indirect causal and associative relationships between effective school leadership and pupil outcomes might be developed" (p. 19).

In the study carried out by Jo Blase, Joseph Blase and Dana Phillips (2010), the authors performed a series of in-depth interviews of 20 school principals designated by the educational authorities and recognized by other sources as principals who achieve high outcomes in their respective schools. The intention was to find out how each of them combined the unavoidable administrative responsibilities with creating an effective school.

Once these interviews had been analyzed, follow-up interviews served to contrast categories, clarify ambiguous areas, and explore relationships among emerging categories.

Qualitative study

In the case studies, for the purpose of collecting observations, we used a set of interviews of the principal, administrative team and certain selected teachers, field observations and notebook, and- finally- discussion groups. Coordinating and analyzing data from three strategies is particularly important in understanding the limitations, possibilities, and future tendencies of educational leadership (Gorard & Tayord, 2004). Schools with good results must be chosen to a greater degree because we are interested in good practices, although contrasting them with other schools with medium and poor outcomes, as was done in the design of the investigation we are following closely (Day *et al.*, 2008; Day *et al.*, 2009). Specifically, we perform the following tasks:

Task 1. In order to collect *good practices in educational leadership, interviews* will be held *with the principal and members of the administrative team* about the most significant aspects related to the study, especially the degree to which the administrative teams work as coordinators, facilitators and motivators of the teaching staff and the life of the centre, playing the role of change agent (proactive, capable of inspiring, instigate lines of work and projects, motivate and persuade). The interviews also take into account the previous results of the questionnaire.

The *semi-structured* interview of the principal, due to the many questions and dimensions to be dealt with, is composed of a reoccurring cycle in three times for gathering information. Specifically, related to the current context of action, we are concerned with:

– *Personal characteristics* of those who have the role of school leaders: values and motivations, trajectories (personal and professional), self-efficacy, attributes and competencies they possess, relations with the community, and manner of responding to complex demands.

– *Leadership practices:* strategies they use, decision-making processes and ways they implement these strategies in response to the unique context in which their work takes place, emotional relations with teachers, and their effects on pupils' learning.

Task 2. *Interviews with selected teachers.* In each high school selected, a set of teachers is chosen for interview. This selection is made once time has been spent in each school and the initial interviews have been carried out with the administration, based on which we determine which people can best act as critical informants for our purposes. In the interviews, according to the investigation protocol, it is important to find out how the teachers experience their work and their degree of satisfaction, their perception of the profession, teaching practices used to improve pupils' learning, etc., as well as how they rate the educational leadership of the administrative teams.

Task 3. *Focus groups*. The focus group has a long tradition in sociological and educational research. We have used it in other studies (Bolívar, 2006b). Our intention is to increase our understanding of the study aims, comparing and complementing personal contributions with those of the group in a more general framework. In this regard, the Focus Group is especially appropriate for understanding the different ways of thinking underlying the topic.

After gathering the information, we will go on to analyze and interpret the information collected in the observations and individual semi-structured interviews for each school. The analysis must combine the diverse elements and dimensions of life in school and leadership, according to the improvement in the pupils' education and learning. Subsequently, individual reports will be prepared for each school, while putting them in three groups: schools with a high level of success, schools with a medium level, and failing schools.

DISCUSSION AND CONCLUSIONS

School principals in Spain, unlike what occurs in the Anglo Saxon environment, often have little capacity to take action with regard to the personnel they are overseeing, which seriously limits what they can do in this area. The principal cannot be limited to administrative and organizational tasks human resources tasks, and instead should attend to anything that can foster better teaching. Therefore, one thing that remains to be done is providing the principal with competences so that he or she can intervene in factors that condition teachers' performances in their classrooms and, as a result, pupil learning.

First, we want to show, in the Spanish context, whether there is a causal relationship between leadership and students' academic achievement. The research design presented here is intended, in this regard, to serve as an example to orient other duly contextualized studies. In general, the idea is to observe the *mediator variables* between leadership practices and learning results, especially the teaching practices. The improvement in

students' learning depends primarily on *first-order changes* (teaching-learning), directed toward making the education more effective. However, –in a *second order*- the leadership teams can introduce new structures and roles that transform the usual ways of doing things. In this measure, the leadership teams direct their activity toward obtaining teachers' commitment and involvement, on the one hand, and their professional development, on the other, by *redesigning the work contexts* and professional relationships. For this reason, they are called the "educational leaders of the school".

Second, in each school we want to analyze the *ways of distributing leadership*, attending to a set of dimensions: forms of distribution depending on the position in the organization, degree of coordination and interdependence, relationship between the power and authority of each leadership role and the acceptance of the corresponding responsibilities, and stimuli for the distribution of leadership. In a broader sense, the intention is to analyze the school culture of working together, planning meetings, leadership at each meeting, etc.

Third, the *good practices* (or, on the contrary, practices that are not good) can be understood as successful ways of doing things. Valuable knowledge can be drawn from them, as they can be guides for action in other contexts. Specifically in our case, good leadership practices are those actions on the part of the leadership team or other teachers that manage to create conditions for improving pupils' learning. In our context, we want to empirically contrast and validate the extended thesis that effective leaders share the same repertoire of basic leadership values, qualities and practices.

If, as it appears, leadership teams have to lead the school's educational dynamics, they will inevitably have to become involved in improving the teaching and learning offered by the school. This cannot be left to the discretion of what each teacher, with better or worse luck, does in the classroom. This point is undoubtedly a source of conflict, but in the international literature and experiences, it is increasingly clear: if the teachers are the key to improvement, the principals have to create an appropriate climate so that teachers can be better. However, it is necessary to recognize that we still have a set of challenges to overcome (Bolívar, 2006a) before we can approach this way of working.

Abstract:. The aim of the present paper is to reinterpret the concept of curriculum leadership from the standpoint of teachers' professional development in the professional learning community (PLC). PLC is a device for the development of curriculum leadership in ways that it promotes teachers' learning, collaboration, decision making and problem solving. Through the authors' researches made for 2008-2010, some exemplary cases of new curriculum leadership are witnessed both in North America and in Japan. Among the findings are that the individual school can recognize more clearly the uniqueness, strength & weakness of its curriculum and gets more information and ideas on curriculum development. The authors attempted to model curriculum leadership based on NLCs through an analysis of those cases.

Keywords: Curriculum Leadership, Curriculum Development, Professional Learning Community, Professional Development

INTRODUCTION

Since the 1990s, standards and accountability have been demanded in school education in many countries including Japan. In the midst of this situation, the concept of leadership came to be adopted in discussions of how school curriculum should be determined. Concerned parties debated the process of curriculum practices brought about by leadership, the role of curriculum leaders in this process, and so on. During these years, we have focused attention on the theory of curriculum leadership as seen from literature on the subject, and examined the concept of curriculum leadership.

We have clarified the following as making up the concept of curriculum leadership: 1) responding to a constantly changing society (that is, innovating) as creative endeavors; 2) when advancing these creative endeavors, the significance of a democratic process for decision-making and resolving problems, which is supported by sharing information and ideas (that is, creating networks); and 3) the importance of management of curriculum as part of the school's organizational activities.

We visited schools in Japan, the United Kingdom, and the United States, and gathered materials related to curriculum development and interviewed several leaders. From our study of the efforts to develop curriculum in elementary schools, we organized the features of practicing curriculum leadership. Based on these features, we proposed a model of leadership roles for carrying out curriculum leadership in Japan (see Figure 1). [1]
Figure 1: Main leadership groups in curriculum development

This model presumes that learning by students and teachers occurs at the same time and resonates together. This model features the gathering of administrators, teachers, students, and practice leaders as a single

community. It focuses on curriculum practices based on partnership and cooperation. This model of curriculum leadership is characterized as a "process" of promoting narrative inquiries in the community. Therefore, in order to develop this process, learning among community members is essential.

Because our focus is teacher development through learning, which is an important aspect of curriculum leadership, we examine in this presentation the relationship between the concept of a "Professional Learning Communities" (PLCs) and curriculum leadership.

PLC AS A DEVELOPMENTAL TOOL FOR CURRICULUM LEADERSHIP
The Relationship between PLC and Curriculum Leadership

The concept of PLC emerged as questions about the quality of students' academic abilities gained momentum in the U.S. from the 1990s. This concept was proposed by Hord in his work Professional Learning Communities: Communities of Continuous Inquiry and Improvement (1997a). Influences that led to the proposal of PLC included research by Rosenholtz (1989) on the teaching profession. He observed the importance of professionalizing teachers from the standpoint of improving students' quality of education and also the importance of sharing what teachers learned and put into practice. He found that 1) teachers who felt "supported" in learning and in teaching had greater levels of enthusiasm and leadership ability; and 2) expanding teacher networks, cooperation among colleagues, and the role of the profession increased teachers' leadership ability. As a result, people became aware that for the teaching profession, which is known as an isolated job, support and networking and community lead to improved job performance.

The introduction of PLC was also based on findings by McLaughlin and Talbert (1993). They described teachers created accumulated wisdom through their own experiences and that they were able to share such wisdom through the opportunities to study and learn together as a group. PLC was also influenced by Darling and Hammond (1996)'s study. It showed that actual reformation of school curriculum was effective not when it was implemented in a top-down manner, but when it involved all teachers in decision-making and secured time for teachers to train together. This suggested the importance of teachers' participation in school decision-making.

Furthermore, PLC took ideas from theory of "the learning organization" proposed by Senge (1990) in the field of organizational management. Learning organizations are "organizations where people continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning to see the whole together." These organizations are strong when it comes to developing.

According to Hord (1997b), PLC has the following five attributes: 1) supportive and shared leadership, 2) collective creativity, 3) shared values and vision, 4) supportive conditions (material, structural conditions; human abilities and qualities), and 5) shared personal practice. In PLC theory, these five attributes are treated as defining characteristics of PLC. For example, Hord and Summer (2008) organized PLC in the manner shown in Table 1.

Table 1: Components of Professional Learning Communities (Hord and Sommers 2008:9)

Shared Beliefs, Values, and Vision	Shared and Supportive Leadership	Collective Learning and Its Application	Supportive Conditions	Shared Personal Practice
The staff consistently focuses on students' learning, which is strengthened by the staff's own continuous learning—hence, professional learning community.	Administrators and faculty hold shared power and authority for making decisions.	What the community determines to learn and how they will learn it in order to address students' learning needs is the bottom line.	*Structural factors* provide physical requirements: time, place to meet for community work, resources and policies to support collaboration. *Relational factors* support the community's human and interpersonal development, openness, truth-telling, and focusing on attitudes of respect and caring among the members.	Community members give and receive feedback that supports their individual improvement and that of the organization.

PLC does not seek to improve schools and curriculum through the powerful leadership of the school administration or a part of the staff. Instead, it does so by involving the entire staff in the leadership process

of making decisions (PLC's democratic aspect), producing creativity that transcends individual power from this collaborative process (PLC's creative aspect), and improving human relationships together by maximizing usable resources and material conditions (PLC's management aspect). Pursing these aspects will promote student learning. However, to create a learning community that includes students, it is essential to have a collaborative organization to unflaggingly nurture learning by teachers who are involved in the leadership process and their professional development. We find overlaps between these characteristics of PLC and the characteristics of curriculum leadership that have been made clear in research up to now. We can understand the relationship between the two by viewing PLC as a developmental tool for advancing curriculum leadership.

Examples of Developing Curriculum Leadership with PLC
In March 2010, we visited schools in the U.S. and Canada and also interviewed staff including principals to understand how curriculum leadership is actually developed using PLC.
We first visited Idlewild Elementary School, located in the western Memphis, Tennessee. After interviewing the principal and leader teachers in training, we observed all classroom lessons. In Tennessee, due to objectives set by the state superintendent, district boards of education and schools are doing all they can to improve students' academic abilities. Specific activities to accomplish this goal are symbolized by standardized testing and formative assessments. At Idlewild Elementary School, PLCs were used as the basic unit for each school year. The teacher leaders of each school year and of each subject (language arts, mathematics, science, social studies, and technology) were assigned to PLCs. The school established 1) collaborative lesson planning time (three times per week for all school years, 35-45 minutes per session) and 2) sharing of teaching plans. Also, teams were assembled to allow teachers in charge of kindergarten children, students from grades 1 to 6, and special classes to work together on the subjects listed above. They called the teams Vertical Team PLCs. Also, a staff member called the Professional Development School Compliance Coach was placed in the school to handle the planning and steering of all the pluralistic PLCs. She not only planned and steered PLCs, but was also responsible for educating parents of the school's efforts.
The term "PLC" is also heard in the Grand Erie school district, located outside Toronto, Canada. Like the school in Memphis, teachers in the school district also felt pressure to improve the test results of language and math abilities. Thus PLC was introduced as a method to meet this goal. For example, in the North Ward Public School, days for PLC were established. On those days "school improvement" teams by the teacher leaders of each school year gave presentations to one another about improving rubric-based lessons (see Photo1). The teachers also shared ideas among themselves on how to improve lessons with rubrics.[2]

Photo 1: Presentation by members of North Ward Public School's school improvement team

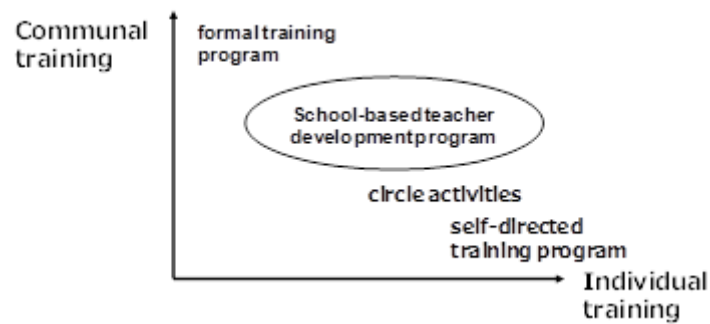
PLCs of Teachers in Japan
Today, teachers in Japan also form PLCs to shape their competencies. It is one of many diverse forms of training that they undergo. We organize these forms of training in a manner shown in Figure 2.


Figure 2: Types of Teacher Development Program in Japan

As can be seen in Figure 2, the teacher training styles are diverse and can be placed along the dimensions of acquiring and improving competencies common to teachers (communal training) and developing separate competencies based on each teacher's own interests and needs (individual training).

"The formal training program," which is planned and carried out by prefectural/metropolitan or municipal boards of education, seeks to form common competencies that administrators believe all teachers should possess at the national or regional level. Therefore the same program is provided to all teachers. Gathering teachers at educational centers for training is a typical example. However, it has become difficult recently to carry out such group training frequently because of the need to maintain classroom time. Thus new teacher training methods have been developed that utilize information technology (e-learning), and many cases of their use have been introduced.

On the other hand, "the self-directed training program" is mainly undertaken outside of work time by individual teachers to address their own needs. All of their independent efforts, including reading books on education, participating in practical seminars and education forums, engaging in fieldwork, and pursuing graduate studies, belong to this category.

In principle, the form of teacher training called "circle activities" (a type of group activities) belongs to the category of self-training. However, this type of training has value as a type of PLC. Circle activities are carried out by communities of teachers that span across schools. These teachers are interested in studying teaching practices. In Japan, activities by what are called "civilian educational research groups" have a long history. These groups provide suggestions concerning the efforts of educators in schools (Tanaka 2005). For example, several groups have played a major role in developing and popularizing educational materials, curriculum, and teaching methods for math and science. New methods for creating classrooms groups have also been suggested by some of these groups and carried out.

These groups form a nationwide educational practice network. Within the network, various research groups, from small to large, are organized and operated in each region. These groups hold meetings every week or so to discuss case studies in classroom practices. About once a year, a major case is discussed by a large gathering. In both instances, circle activities provide valuable opportunities as PLCs for Japanese teachers. This has remained unchanged over the years.

One more form of teacher training needs to be discussed. This is called the "the school-based teacher development program," and is held within schools. This program is a PLC of teachers who belong to the same school. For teachers who come in contact with the same students and teach under the same conditions, they of course share challenges and need similar methods of coping (that is, they share common ground). However, in general teachers have a wide range of educational practices and have different experiences and orientations, even in the same school. Therefore school-based teacher development program must satisfy the individual character of teachers without violating the collaborative character of their situation. Furthermore, because different schools have different challenges, even if they belong to the same area, the common ground within a school differs between schools. In other words, attention should be paid to the fact that the school itself has individuality.

The main pillar of school-based teacher development program is the "lesson study." This is a conference that discusses a lesson carried out by a teacher. For a lesson study, a teacher designs and conducts a lesson, which is observed by the rest of the staff members. After the lesson, the teacher and observers hold concrete, multifaceted discussions on the design of the lesson and its execution. In other words, a lesson study uses a case study approach to consider how to create lessons (see Photo 2).

615

Photo 2: Lesson study in progress

PLC Networking to Promote Curriculum Leadership

PLC is generally established on the basis of individual schools. It is linked to "School-Based Curriculum Development," and the community is centered on teachers who investigate problems together. This exploratory community connects person to person; that is, it has the power of a network. Therefore, it is inevitable that this community would connect with "communities of narrative inquiries" of other schools. In other words, the PLC becomes networked. Furthermore, by becoming networked, the PLC becomes even more powerful. A network is a "powerful organizational tool" (Katz, Earl, and Jaafer 2009). Compared to a single PLC, networked learning communities (NLCs) produce, store, and share among their members even richer collective wisdom. At the same time, NLCs have the ability to treat excellent curriculum practices as collaborative property belonging to a widely networked organization that transcends single schools. NLCs can spread these practices throughout the organization.

As we described earlier, we visited the board of education and primary/middle schools in the Grand Erie district in Canada. We interviewed them about the curriculum leadership in practice. We also identified a case of PLC networking that is worthy of mention. This is called TLCP (Teaching and Learning Critical Pathway), which is combined training program that spans schools. Several times a year, teachers from multiple schools gather at a teachers' center or school and exchange views on improving education. In short, it is peer assessment among schools. It is a strategy to widely obtain ideas on the suitability and even the possibility of school improvement plans that are decided by each school. In the midst of pressure exerted by standardized academic testing on teachers and their risk of being agitated by competition between schools, this effort contributes to creating an approach for improving students' academic abilities that builds on the unique foundation of each school. In addition, we heard that an association of school principals also sends advice on improving schools to one anther. We also heard about this activity when we visited schools in England.

In Japan, improving curriculum practices through PLC networking can be found in events such as practical research conferences. As we mentioned earlier, Japanese elementary and middle school teachers share enthusiasm for lesson studies. They have created a teacher culture that respects such training (Kihara 2006). Symbolic of this culture are practical research conferences called Teachers' Conferences on Curriculum Practices. These events, planned and carried out by teachers, are opportunities to present to teachers of other schools the school-based action research of one's school and its results (Kihara 2009a). In the past, expert teachers from a few prominent schools provided demonstrations of model lessons. Today, however, such demonstrations are being redefined on the stage of a practical research program called "Collaborative Action Research among Schools." Because of this, programs at practical research conferences have become more sophisticated. For example, in addition to conferences that discuss lesson studies, there are more cases now of programs that incorporate poster presentations on classroom practices developed by teachers of the host school as well as workshops on improving lessons. These activities go on until the day of the practical research conference (see Photo 3).

616

Photo 3: Poster presentation and workshop on curriculum practices

Because of these activities, more exchanges take place between teachers of the host school and participating teachers on wisdom related to "curriculum wisdom". The purpose is to make sharing and exploring curriculum practices an even richer experience.

In addition, in Japan curriculum practices that are created by the collaboration of elementary and middle school teachers are currently gaining in prominence and maturing. According to Kihara (2010), these can be divided into the following activities:

1. Exchanging and sharing information and data on children's academic abilities
   Joint analysis of academic test results and survey results of students' living conditions, etc.
2. Sharing understanding of key points for teaching
   Establishing key points for guidance concerning study habits and rules, etc.
3. Developing team teaching
   Middle school teachers participate in the lessons of elementary teachers, etc.
4. Flexible organization of learning groups
   Elementary school students interview middle school students during "the Period for Integrated Studies", etc.

For example, in case of Example 3 above, when an elementary school teacher and middle school teacher expand team teaching, they become active in exchanging views and participating in joint tasks that concern the growth and development of children. This is because there are more specific opportunities to discuss concepts and styles for creating lessons.

Photo 4 shows a typical example. It shows a Japanese lesson in a fifth grade class. The assignment was to make video news segments about the school that is easy for others to understand. The fifth-graders' interview subjects were middle school students who graduated ahead of them (in other words, their "sempai") and fifth-graders from another school who will go to the same middle school (in other words, their future classmates).

A middle school teacher of Japanese evaluated the validity of the news materials and presentations produced by the fifth-graders. Because she understood the middle school students' perspective and situation, she was able to give honest criticism to the fifth-graders.

Photo 4: Team Teaching between a primary and a middle school teacher

At the same time, the middle-school teacher could promote herself to the students, many of whom she will teach two years later. She could also deepen her insights into the possibility of projects at the elementary school.

STRUCTURAL UNDERSTANDING OF CURRICULUM LEADERSHIP
Model of Curriculum Leadership That Focuses on PLC
By developing joint curriculum between schools, good ideas for curriculum practices can be shared, and the "personality" of the curriculum of each school is made more conspicuous. This dual orientation is established by fully using the functions of PLC. Figure 3 shows a structural model of curriculum leadership based on such considerations. This model is a reconstruction of the conceptual model of leadership groups that advance curriculum development, which we presented earlier (see Figure 1). In the new model, we incorporate the perspective of PLC.

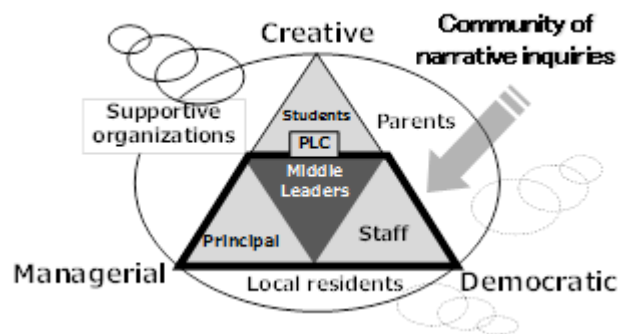
Creating and Growing a Specialized Learning Community and Networking with Other Communities
First, the staff of a school seek to develop curriculum that contribute to the learning of students, while being involved with diverse members, including the students and parents in the region. Then, through four activities (collaborative lesson planning, securing and using resources, creating a teacher culture in which teachers learn from one another, and acquiring theories and models), leaders of practices, the administration, and general teachers develop a specialized learning community. In such a case, curriculum leadership is a process that creates and grows a community that discusses and explores ways to make students' learning richer. Such a community can be considered a joint organization for exploring ways to continually promote teachers' learning and professional development.


Figure 3: Structural model of curriculum leadership that pays attention to PL

In this model, PLC is seen as a community that allows teachers to continue learning and improve their competencies. In other words, it serves as the foundation of community of narrative inquiries. Then, by becoming networked and by networking with other PLCs, the PLC resonates with the growth of other PLCs. The result is the creation of networked learning communities (NLCs), where richer collective wisdom is created, accumulated, and shared among members. Teachers who "connect and learn" develop this capability even further by networking not only in their own schools, but with the PLCs of other schools. Such connections with others (other schools) are created not merely for the sake of networking, but for serving as a cultural tool to improve the competencies of teachers.

CONCLUSION
The greatest significance of the model presented here lies not only in the creation and growth of PLC within schools, but in the possibility of making curriculum development more fruitful by networking with the PLCs of other schools. According to Sato (2000, p. 122) "how the development of school- and classroom-based curriculum, which mainly involve teachers, is established in schools, and how education administrations and teachers' centers support the school- and classroom-based developments, and how this developmental process is researched and generalized, are critical questions that will determine the success or failure of developing future curriculum." Related to this observation, questions may have also been raised on the possible closed nature and conservativeness of lesson studies and school-based teacher training program (Kihara 2006, Abiko 2009, etc.). [3] To address these questions, this presentation argues that by collaborative curriculum development among schools, good ideas for curriculum practices can be shared and accumulated (that is, collective wisdom is produced). This is accomplished by putting in place a full-powered, dual-oriented PLC, which makes the "uniqueness" of the curriculum of each school conspicuous. Good examples of this proposal include the Teaching and Learning Critical Pathway program in the Grand Erie school

district, which is joint teacher training that encompasses the schools in the district. Other examples are practical research conferences in Japanese schools and collaborative educational activities between Japanese elementary and middle schools. These efforts embody the developmental attitudes of a "community of narrative inquiry."

NOTES

1. These results are provided in detail in our report Modeling the Role of Leadership Groups in School-Based Curriculum Development (Heisei 18 – 20 [2006-08] Ministry of Education, Culture, Sports, Science and Technology Grant-in-Aid Report) (March 2009).

2. The "school improvement team" in North Ward Public School's case consisted of ten staff members, namely the principal, vice-principal, and head teachers of each school year. Their role included creating school improvement plans and planning and implementing training inside the school. When asked about the features of this team, they replied that their activities were based on analysis of data from tests given by the provincial government's Education Quality and Accountability Office.

3. For example, Kihara (2006) observes that "training and research activities in schools until now have a closed nature." He believes that this is because teachers respect conditions that have formed in the schools they belong to, based on the schools' history of practices. He states that teachers should shirk such exclusiveness and avoid sinking into inertia though the style of lesson studies and curriculum development at their schools are worthy (p. 17). Abiko (2009) states that "study groups in Japan currently do not exchange much opinion and information on lesson studies. Therefore, even though what they are engaged in is called 'lesson studies,' what they learned is limited to the group, and their insights do not reach other groups" (p. 19).

"Educators should encourage students to experience the richness of the world, empower them to ask questions on their own and reach answers of their own, and to present and challenge them with the complexities comprising our world."(Brooks and Brooks, 1997)

PROLOGUE

Israeli society is imbued with a feeling of growing dissatisfaction with its students' achievements in the areas of reading and writing. This feeling has been well expressed in the media and in debates held in both the Knesset Education and Preschool Education Committees of the Ministry of Education. Following the disappointing results of the Israeli children in reading comprehension tests, it was decided to begin promoting literacy from early childhood.

As professionals, we indeed believe that literacy should be promoted in a manner that suits the abilities of kindergarten children and that the process of acquiring reading and writing skills depends not only on the acquisition of the code, but also on the reading comprehension of the texts. Based on the studies that suggested the connection between imaginary play and literacy (Blum-Kulka and Hook-Taglicht, 2002; Sawyer, 1997; Harris, 2000), an Early Childhood Department team at Kaye Academic College decided to incite educational activities towards the development of a literacy discourse during 'make-believe' pretend play following story-reading.

Furthermore, it was decided to follow these activities with research and study, driven by the inner need of the team to develop and improve its professional level. In the following section, we will focus on these accompanying study groups, which included educational supervisors and women student-teachers, and we will examine the influence on the participating students.

Pretend play as a means of fostering cognition and linguistic skills in children

Many researchers have emphasized the importance of symbolic play as a means of fostering children's cognition and linguistic skills. (Sawyer, 1997; Göncü, Mistry & Mosier, 2000; Bergen, 2002; Carruthers, 2002; Blum-Kulka, 2002). Symbolic play is an arena in which symbolic skills are developed, to be implemented later in other areas, such as reading and writing. (Pellegrini & Galda, 1991; Williamson & Silvern, 1991).

According to Harris (2000), processes that require coping with reading comprehension develop when children engage in 'make-believe' pretend play. He asserts that, through these games, children learn to temporarily suspend their immediate reality and to enter another, imaginative one. This ability is also required in order to glean meaning from written texts, when the child is also required to temporarily disengage from reality and to enter the world of the text. Pretend play helps children to develop the crucial improvisation skills they need in their daily lives and it fosters their oral culture. Sawyer (2001) has pointed out that pretend play involves negotiation between players, children make proposals and collaborate when engaged in pretend play, and they learn from children (informal, implicit and natural learning).

In general, the project was executed as follows: a student-teacher read a story to a group of children, after which they pretend play it independently, without any adult guidance or intervention. The children were instructed: "Now go pretend play the story". According to the preliminary planning, the student-teacher brought various props relevant to the story she had read, taking care that these props would not unduly limit the game, leaving the children to use their imaginations. This pretend play was done at a predetermined location, during which the verbal interaction was documented by two supervising student-teachers (the one that had read the story and her helper), in an attempt to gain as much verbal or other information as possible. Simultaneously, each 'make-believe' session was recorded on video (by a professional video expert on behalf of Kaye College). Eventually, the student-teachers transcribed the oral records, based on the videos and their written protocols. These transcriptions were analyzed and served as the basis for all the conversation analysis in the research that accompanied the project.

THE RESEARCH AND STUDY FRAMEWORKS THAT ACCOMPANIED THE PROJECT

The learning process regarding the pretend play consisted of four parallel frameworks:

1. **Team meetings** – of the educational supervisors that lead the project de facto;
2. **Learning workshops** – held by a combined learning group, that included both the participating student-teachers and the course's educational supervisors;
3. **Study sessions** – of a study and research group headed by Prof. Hava Tuval from the David Yellin Academic College of Education, which also included experienced kindergarten teachers and educational supervisors;
4. **Meetings for all the project participants.**

The research was conducted as follows:

The years **2001-2002** were dedicated to the preliminary study of literacy by a research group composed only of educational supervisors.

During **2003-2004**, the various frameworks were created: **team meetings, learning workshops and study sessions**. The student-teachers were taught and acquired observation and conversation documentation skills (transcription and video-filming), which they implemented. Discussions that took place during the workshops pinpointed certain conversation variables to be studied following a survey of the relevant research literature and our own experimental discourse analysis methodology.

In **2005**, some of the third-year student-teachers, who had participated in these study workshops, chose to further examine education issues raised by our research as their theses topics.

In **2006**, two courses dealing with qualitative research, observation skills and discourse transcription and analysis were designed for all the student-teachers studying preschool education. Pedagogic workshops included several sessions dedicated to the role of pretend play in the wake of story-reading. The number of student-teachers who chose to study children's discourse swelled beyond the initial number of learning-workshop participants.

From **2007-2009,** the onus was on the assimilation of the research conclusions into the kindergartens and first and second grades and on conducting school workshops. The student-teachers established educational environments enabling children to engage in a pretend play after story-reading.

Since even our own **learning frameworks** were new to us, we decided to guide, shape and evaluate them by means of more research, also seeing ourselves as a **'learning community'** and viewing our novel process as a new way to train early childhood teachers.

RESEARCH FRAMEWORKS AND STUDY AS A 'LEARNING COMMUNITY'

The constructivist approach to learning

For many years, the prominent approach in teaching viewed the teacher as being a 'knowledge supplier' or 'knowledge transmitter'. As a result of this traditional, hierarchic approach, teacher training was based on imparting skills acquired by observing and imitating the more experienced teachers. According to this method, known as the 'funnel model', the learning process takes place when "the teacher teaches and the student learns" (Keiny, 1998).

Unlike the traditional approach, over the last two decades constructivism has been accepted by most researchers and theoreticians. It claims that the teacher's knowledge is in no way superior to that of the student. Information is a product of personal and subjective structuring, evaluated by its vitality and utility. Such new approaches pose challenges to the educational system, in general, and to teacher training, in particular (Back, 1999, 2006). Back (2006) argues that teacher-training institutions still 'overuse' the traditional and hierarchic methods of teaching. He criticizes teacher training based on the rational-technical perception, commonly practiced in recent decades. This rational-technical approach, which sees the teacher merely as a teaching expert, rather than as educator, no longer satisfies us (2006; 304). Modern society suffers from many ills: "… healing necessitates a different sort of teacher, one who can be with students and knows how to nurture them in a process during which he/she him/herself imbues the students' lives with meaning" (ibid., p. 368). Such teachers require a different type of training program.

Our research team faced this challenge by creating a learning community in which we implemented the principles of the constructivist approach.

A 'learning community' as an expression of the constructivist approach

According to Brown & Campione (1994, 1996) and Wenger (2004), a 'learning community' is born when a group of people with common goals engage in shared, continuous, systematic learning. In essence, a learning community consists of people having a common denominator or similar interests. Such a community undergoes an active and dynamic process in which it members learn cooperatively, share knowledge and

engage in personal and collective reflection (Pringle, 2002). Shulman (1995) asserts that learners learn best in a community of learners. He claims that teachers can improve their work by becoming members of communities in which they might actively investigate their teaching methods and do so willingly and collaboratively.

Keiny (2006) discusses the concept of a 'community of learners' in her study of a community whose members were teachers, researchers and practitioners, who participated in a reciprocal process of experiencing, learning and the construction of new knowledge. She further defines a 'community of learners' as a group of learners that acknowledges the differences between its members and encourages individual freedom of expression. Keiny argues that a 'community of learners' is autonomous and self-organizing; community members decide their own agenda and take responsibility for their performance be means of a process of knowledge acquisition and its resulting 'products'. Each individual is a major component in such a community, operating on two levels, both as a participant, involved in its inner processes, and as a reflective observer, aware of his/her actions and thinking about them. The learner and the community are mutually dependent, because they nourish each other. The personal growth of the learner and the individual knowledge accumulated contribute to the growth and knowledge of the learning community as a whole. Thus, the overall accrued knowledge shared by the community supersedes that of each individual learner.

In light of the above, Keiny calls the learning community an 'ecological system', in which each component affects the others and is affected by them (Sergiovani, 2002; Keiny, 2006). Such a system assigns major importance to the communication that takes place between its components and is based on the constant, multi-directional flow of information, feedback, openness and flexibility. This communication enables the system to survive and evolve by maintaining the balance between its components. Thus, listening, enhanced communication, understanding and cooperation between its members are primary requisites for the creation and functioning of a learning community and for successful cooperative learning (Sanjee, 1995; Keiny, 2006). In a community of learners, learning is perceived as an interactive construction process, in which all the learners – adults and youngsters – create new insights through constant dialogue with themselves and others (Vygotsky, 1978; Perkins, 1998, 2000; Bal and Cohen 1999). A learning community supports its members in their process of coping with challenges and changes in their proximate working environment, making it a continuing education--practical 'lifelong learning'.

In a teacher-training institution with such a learning community, its members are engaged in shared learning activities yielded by their constant, reciprocal consultation. The learning community is based on peer experience and the lessons learned from it. The members pool their individual knowledge, integrating it into the common system, strengthening the shared resource (Roth, 1998). This can be done in a number of ways: by conducting action research; by observing the teaching techniques of other teachers; by attending lectures; by means of conversations with guest experts, etc.

Study groups as learning communities and the place of women students in them

The constructivist perspective has several implications for the research and learning groups that accompanied the developmental literacy discourse project in light of the children's pretend play after story-reading. Our community of learners, which included trained kindergarten and school teachers, educational supervisors and student-teachers, was created at the outset of our research dealing with pretend play after story-reading. This course of action was the outcome of trial-and-error processes employed by the supervisory team when examining new ways of working with prospective teachers and was aimed at encouraging **mutual responsibility** for the learning process. One of the learning frameworks was the combined workshops for educational supervisors and student-teachers, meant to establish egalitarian teaching/learning methods, in which the supervisors were not considered to be the sole possessors and sources of knowledge, merely 'data transmitters'. Great emphasis was put on the perception that sees the students as **full-fledged partners** in the learning process and enables interaction between them and their educational supervisors. Such interaction would lead to **shared learning** by raising doubts, reservations and dilemmas. We hoped that by training student-teachers according to this newly-created teaching/learning model it would strengthen the connection between theory and practice and promote its *in situ* application in future.

The research questions

During our research, we discovered that the processes which took place within the **learning community** framework were of no less important and intriguing than the findings related directly to the research itself. Therefore, it was decided to study these processes, believing that such experimental research, within the framework of the learning community as it occurred in the department, might serve as a crucial asset to both our initial research and to teacher training in general. Thus, the following two integral questions arose:

a. How did the participation of the student-teachers in this research influence their learning and involvement in the community?

b. Is there 'another way' to conduct teacher training that would produce a different model of the prospective teacher's professional development? (Vardi-Rat, Eylon, Cohen, Ohana & Lewin, 2005).

This paper attempts to answer these questions.

LEARNING PROCESSES IN A LEARNING COMMUNITY

Learning by asking questions

During the process of the construction of knowledge, we think that an important place should be reserved in which the learner may ask questions; the posing of questions is an essential, intellectual tool for any learner. While, during a natural conversation, questions are asked to get information one does not have (Searle, 1969), in the educational context, the tables are often turned--the person asking the questions may be the one who actually knows the answers (the educational supervisor, mentor or lecturer), while the person being asked is the student (prospective teacher) who lacks that very knowledge (Cazden, 1992; Dillon, 1988).

Harpaz (2000) assigns great importance to the skill of questioning, because it indicates: the detection of missing knowledge; causes the asker to be active in his/her personal process of learning; and requires a degree of involvement and creativity in the formulation and presentation of the relevant question. Harpaz (2000) defines a productive question as one that contains the following basic features:

a. **An open question** – one without an unequivocal answer;
b. An undermining question – one that exposes conflicts and requires original thought;
c. **A enriching question** – one that necessitates coping with its rich contents;
d. **A connected question** – one relevant to the lives of the learners and their society;
e. **A charged question** – one with ethical ramifications;
f. **A practical question** – one that can be shaped into a research question and the learners have accessible information to study and answer it.

Recognizing the importance of asking questions during a process of teaching and learning in a learning community, our paper deals primarily with productive questions raised at our community learning workshops.

Learning as 'knowledgeable performance'

We perceive of prospective teachers as being able to think and act by using their knowledge flexibly, creatively and skillfully. They should enable their young students to demonstrate the applications of knowledge, beyond rote memorization and the mere recitation of facts. In our opinion, the focal learning framework in this study does enable the participants to construct new knowledge through active experimental learning. Our approach matches the constructivist approach, implying that learning is not a matter of the mere transfer, acquisition or integration of ready-made information relayed in appropriate 'doses' and in some 'appetizing' form, but rather the process of the active construction and transformation of information into knowledge (Brooks & Brooks, 1997; Glazerfeld, 1996).

We asked ourselves: How would we know that learning had indeed taken place in the community? How might the participants display comprehension of the acquired concepts, principles and skills? We found that the concept of 'knowledgeable performance' provided some answers to these questions. 'Knowledgeable performance' (Perkins, 2000) is the ability to perform thinking processes by means of 'knowledge on knowledge' or 'meta-knowledge', such as: expressing knowledge in your own words; providing examples of this knowledge; identifying associated knowledge; placing knowledge in its context; bring forth evidence of knowledge; comparing cases, phenomena or claims; criticizing knowledge on the basis of knowledge; creating knowledge on the basis of knowledge; presenting knowledge, etc. Knowledgeable performances are subject to definition, discovery, feedback and fostering (Wiske, 1998; Harpaz, 2000). Our study deals with the issue of identifying knowledgeable performance within the learning process of the learning community.

Motivated involvement in learning

In the constructivist worldview, good learning is **involved learning**, in which the learner is interested in his/her studies and has intrinsic motivation. An engaged learner treats information with affection, inquisitiveness, criticism and creativity (Harpaz, 2000). The desire to learn grows out of an individual's experience of personal interest and pleasure, when given the free opportunity to choose to be involved when ready to do so and not by necessity or under coercion.

According to Assor (2001), intrinsic motivation includes high levels of intensity (the degree of desire to invest in the relevant activity) and a sense of autonomy (a feeling stemming from the selection of the mission, understanding and identifying with it). Extrinsic motivation, on the other hand, stems from external factors and is characterized by a sense of coercion, an absence of meaning and feelings of fear and anger. Assor (2000) lists at least five good reasons for fostering intrinsic motivation:

a. The positive emotional experience – intrinsic motivation is accompanied by a sense of pleasure and interest;
b. The means for building an identity – intrinsic motivation helps a person to discover his/her real interests and to find directions for suitable action;
c. The facilitation of deep and creative learning – intrinsic motivation leads the learner to deeper processing of those theories and concepts being learned and their relationship to personal reality being confronted;
d. The contribution to the learning community – the freely chosen membership of the learner to his/her group and the consequent interest in its actions contribute to the social atmosphere in the group and to the promotion of its objectives;
e. The fostering of cognitive aspects – intrinsic motivation is significant for learning that requires analysis, synthesis and implementation of the studied and learned concepts.

Due to the importance of this topic, our research focused on the following issue: Which expressions of motivated, involved learning were evident in the student-teachers in our learning community?

The research questions
To summarize, the examined research questions were: Which student-teacher expressions relate to productive questions, learning performance and motivated, involved learning? What are their conclusions in regard to teacher training?

The research approach
We have chosen a qualitative approach toward the development of the ability to systematically and reliably observe, analyze and reach conclusions regarding authentic educational events, documented by means of collected data (Tzabar Ben-Yehoshua, 1990).

THE RESEARCH METHODOLOGY
The research population
The population participating in the learning community process included:
- An academic consultant – Prof. Hava Tuval from the David Yellin Academic College of Education;
- 7 educational supervisors from the Early Childhood Department;
- 4 in-training kindergarten and school student-teachers, who showed interest in the subject and dedicated time to learning and research;
- 12 Early Childhood Dept. students (4 of them third year and 8 second year), who volunteered freely as of their interest in the topic.

Data collection
Data collection was based on the following sources:
- 13 team meeting protocols from 2003;
- 11 study session protocols from 2003;
- 14 learning workshop protocols from 2003;
- 10 student interviews;
- Two interviews: one with a student-teacher and another with a kindergarten teacher;
- Four interviews with educational supervisors.

The method of analysis
In order to determine meaningful categories, the interviews were analyzed structurally and systematically. This method is based on the division into meaningful categories in a way resembling that of Corbin & Strauss (1994), which analyses social reality from the subjective viewpoint of those acting in and experiencing it. This method helps researchers to do a qualitative analysis of the data by characterizing and

categorizing significant discourse units. The unit of analysis is not necessarily a single expression, but rather a cluster of expressions on a particular topic. This method of analysis has a number of components:

  a. The reading of the protocols from: team meetings, study sessions and learning workshops, interviews with students, in-training kindergarten and school teachers and educational supervisors. All the protocols had been written manually by two instructors. The various meetings were recorded on tapes for documentation and backup purposes;
  b. Locating and designating categories for encoding via additional reading or identifying common, repeated themes in the documentation;
  c. Determining which categories are significant;
  d. Additional reading and determination by a second, independent researcher for the sake of inter-judge reliability in the setting of the analytic categories.

Inter-judge reliability

Our qualitative study lends itself to different interpretations. Different researchers may see the same data at the same time and, nonetheless, reach different conclusions. Therefore, the data was examined by two independent researchers to minimize the subjective researcher bias and to reach inter-judge agreement. High positive correlation was found among the researchers, indicating high reliability. In our research, the findings enjoyed a very high level of agreement. Findings that did not gain a sufficient degree of agreement were assigned to a separate analysis. The researchers examined ten protocols of the conducted learning workshops (of the 14 protocols in total; see "data collection" section above). The inter-researcher agreement level was 97% (Kippendorff, 2004).

THE FINDINGS

Learning by asking productive questions

During the course of our research, a learning process took place via the mutual deliberations of the student-teachers and educational supervisors. Often, we had to face ambiguous situations, in which the methodology was not straight-forward. Many questions surfaced, creating the need to find the answers by trial and error. The student-teachers were equal partners in both asking the questions and making the decisions. They presented their experiences and determined, to a certain degree, the subject-matter and progress of the research. There were deliberations in many areas that lead to open and productive questions. The following are some examples of the questions asked by learning community members:

Example 1: Is pretend play after story-reading really 'make-believe'?

Learning Workshop 2 (from 13/11/2002) hosted a debate concerning a very critical issue raised by a third-year student: Is pretend play after story-reading really 'make-believe' or just a dramatization? This question had already surfaced earlier at the same workshop and resurfaced to its importance. This question is an 'undermining question', an attests to the ability of the learning community members to debate their previous knowledge and question it. This issue arose due to differences in the definition of the concept of 'free play', since the pretend play game that occurred following the story-reading was initiated by the student-teacher, unlike 'free play' in a kindergarten, which is usually initiated by the children themselves.

Learning Workshop 2 (13 November, 2002)

  Educational Supervisor A: We saw, in the transcriptions received so far, that this is a very prominent element. The children are engaged in negotiating the framework even before the game. Pellegrini and Galda (1991, 2000) speak about the ability to talk about the game and meta-game; this is not the game itself, but talking about the game. By setting the frameworks, they engage in a meta-game.
  Student-teacher A: The question is whether it's a game and not dramatization?
  Educational Supervisor B: It's true that it wasn't something the children initiated, but we're giving them a choice.
  Student-teacher C: Perhaps I should tell the story and introduce props related to the game to see whether they'll would take them and play?
  Student-teacher D: Maybe it's better to leave the game spontaneous and see if it continues?
  Student-teacher E: I've made a distinction between the concepts of 'make-believe' and 'dramatization', which is more closely related to the text. I think that what we're doing is role-playing; there is pretend play, but everyone has a role.

Educational Supervisor C: Free play, 'make believe' and role-playing are synonyms.

During the discussion described above, we tried to think how to cause the children to pretend play the story instead of dramatizing it. We discovered that the fine distinction between 'make-believe' and dramatization depends on the preliminary instructions given to the children. It was found that the instruction that caused pretend play is: "Now, go pretend play the story." Whereas, the instruction leading to dramatization was: "Now, let's present the story".

Example 2: Why do a large percentage of the children playing 'make-believe'
At the learning workshops, the student-teachers and educational supervisors were given projects related to the transcription analyses and debates were held concerning the analyses and interpretations of certain expressions. This type of question is an open question that does not, in principle, have an unequivocal answer. It enables the learners to expand their concepts and restructure previous, limited knowledge.

At **Learning Workshop 5** (30/12/2002), we analyzed the transcription of a children's conversation following pretend play after a story-reading and clarified the difference between the playful activity and those activities dealing mainly with planning and the assignment of roles for the game itself (play vs. meta-play). The cooperative analysis of the findings by the workshop participants revealed the need to discuss them extensively and raised more hypotheses to clarify the differences between these concepts.

Learning Workshop 5 (30/12/2002)
> **Educational Supervisor A:** Perhaps, because the story is an unfamiliar one; perhaps the whole prelude is because each child comes with what he's got.
> **Student-teacher B:** Maybe all the necessity to play cooperatively takes time.
> **Student-teacher C:** Perhaps, acting out of character is a part of a need; perhaps the same reasons they didn't proceed with the story also caused them to deal with handing out the roles.
> **Student-teacher D:** Perhaps, if the costumes had been ready in advance, getting into character would have been quicker.
> **Educational Supervisor B:** Maybe we should try and see what will happen with costumes?
> **Student-teacher D:** The children are still at a stage where they quarrel over the characters; adding costumes would cause chaos.
> **Student-teacher E:** I did a demonstration of the "Three butterflies" story; they played with the props. When the props were there, they didn't argue who would be who?
> **Student-teacher F:** Perhaps, the costumes would cause another problem. If you didn't want to be a certain character, [seeing] the
> costume [there] might force someone else to choose that character

Example 3: What is the difference between the terms 'mediation' and 'scaffolding'?
.

At **Learning Workshop 8** (5/3/2003), we discussed the article "The strategic learning of new words in contextual storytelling" (Kuzminsky, 2002) and examined the issue of children as learning mediators during 'make-believe' games as compared to adult learning mediators. In the presented example, we saw that the difference between the terms **'scaffolding'** and **'mediation'** is not entirely clear, raising a substantial question, requiring dealing with contents which are vital to the understanding of the child and his development.

Learning Workshop 8 (5/3/2003)
> **Educational Supervisor A:** What is 'scaffolding'? And is there a difference between 'scaffolding' and 'mediation'?
> 'Scaffolding', by Leah Kuzminsky's definition is: "providing adequate support to help the students succeed; the nature of this support depends on the student's performance…
> **Educational Supervisor B:** 'Mediation' is conducted to prevent the need for scaffolding.
> **Educational Supervisor C:** 'Scaffolding' emphasizes focal failures.
> **Student-teacher A:** 'Scaffolding' is temporary and pinpointed, while 'mediation' is broader.
> **Educational Supervisor D:** 'Mediation' is planned, but not focused.
> **Student-teacher D:** We're in the field and try to build on what they're doing. In 'scaffolding', we plan in advance – more focused.

Educational Supervisor E: Perhaps 'scaffolding' and 'mediation' are the same. I'll clarify this with Leah Kuzminsky by E-mail.

To summarize, productive questions were asked in the midst of the mutual learning process, motivated by a number of factors:

a. Their relevance to the research process;
b. Their bearing on theoretical understanding and conceptual clarification;
c. Their arising from the field or connecting theory and practice;
d. The deliberations;
e. The connection between inquiry and learned knowledge;
f. The shifting of attention to new questions inspired by answers found to prior questions, i.e. every solution creates new problems.

In light of the many questions generated during this process, we created a 'question bank', i.e. a database of questions, each of which could serve as a future research topic for our or other students or educators.

'Knowledgeable performance' as learning

The section below presents examples of the knowledgeable performance of student-teachers from our learning community. The combined workshops held took into account the various contexts experienced de facto by the research participants working in kindergartens and schools. In the following example, by raising personal experiences, it was possible to learn about the development of each student in light of her own personal experience; in other words, it was possible to detect individual knowledgeable performances, such as the ability: to identify certain contextual knowledge; to express knowledge in her own words; and to provide real examples of knowledge, based on personal fieldwork.

Example 4: Learning Workshop 12 (2/4/2003)

Student-teacher A: On Monday, I recorded "Raspberry Juice" [a popular Israeli children's story]. There was a lot of meta-playing. They argued a lot and raised various arguments – the explanatory genre. There was a girl who dominated everyone and she wanted to be Raspberry Juice [the main character]; a very quiet child also insisted on acting this character. Eventually, they both did the character. In the end, there was a debate on how to end the story.

Student-teacher B: I did the "Hannah and her Sabbath dress" story… There wasn't much talking, very slow…. I tried to encourage them a little. The story was OK, but it was obvious this was their first time.

Student-teacher C: I did the "Mouse in the house" story with two groups: an experienced group and one that doesn't usually act. There were very significant differences.

Student-teacher D: That's why it's important to work with all the kindergarten children from the very beginning of the year.

Educational Supervisor A: This is a very educational conclusion that goes beyond our research. If we want the children to pretend play, we should start them off from the beginning of the year.

The process of learning in the workshops was active and helped to develop self- awareness and motivation toward continuous inquiry. Most of the workshops were planned in such a way that the main part of the workshop had activities including: analysis, term clarification, raising questions and discussion. Likewise, a great deal of latitude was exercised when accepting the various events and learning cases, presented mostly by the student-teachers. In these examples, we can see how the student-teachers succeeded in displaying knowledgeable performance thanks to: the explanations they gave for the pretend play events on the basis of their previous knowledge; their justifications of the possibilities, expanding them and attempting to forecast the results, in order to prepare their next moves. The participants discussed the matter of understanding the children's story before the pretend play event. This matter surfaced when the students experimented with very young children (3-4). One third-year student reached the conclusion that she should alter the nature of her work with young children to add a conversation about the story. This example shows how new knowledge can stem from previous knowledge in a learning community.

Example 5: Learning Workshop 9 (19/3/2003)

Student-teacher A: In my "Apartment to rent" story, one girl lead the game. She told the other kids what to say and they sat down and repeated what she'd said.
Student-teacher B: In my case, the children didn't succeed in playing and stuck to the story.
Student-teacher C: That's why I'm talking about the story.
Student-teacher D: Talking about the story before the game can have affect their understanding later on.
Student-teacher E: That's why it's worth talking about the story and repeating it, rather than talking about understanding.
Educational Supervisor A: In an unfamiliar story, it's recommended to recreate the story.
Student-teacher F: It's possible to try the same story again with the same group.

Motivated, involved learning
The findings related to 'involved learning' revealed that intrinsic motivation plays an important role in the student-teachers' learning process.

1.   Intellectual curiosity
Student-teacher A: In general, everything hasn't crystallized yet. As for the dramatic 'make-believe' in the corners versus the pretend play after the story-reading--we have study both. What most intrigued me was the verbalizations, rather than the discourse. Because, for example, when I was watching children playing 'house' and children playing after story-reading, I could also see…. It depends on which game of 'house' they're playing… When they played a mother grating, cooking and preparing food for her children, there were three girls in the corners that virtually did not speak to each other. It was only something like: "Pass the plates!"; "Give that to me!"; "Go over there!"; "Do this!"; "Do that!" – very little verbalization. Verbalization was virtually non-existent, but action was considerable. On the other hand, I saw a group of boys playing something more imaginative in the corner, as if they were in a spaceship, and then they went to the sea and there really was much more verbalization. This is where the issue we were talking about is felt—exclusion--which also impacts on verbalization versus action. This is the main point.
Her discovery, of the connection between the theme of the game and the degree of verbalization, aroused interest among the community participants and, later, that same student-teacher opted to study this topic for her final paper. Clearly, she felt free to try new ways of thinking, new directions and methods of action and, as a result, displayed greater flexibility and creativity.

2. Controlling the skills
The examples above reflect the readiness and intrinsic motivation of these student-teachers to improve their mastery of the required tasks and of the knowledge being studied. Our research participants referred to the fact that being engaged in the research substantially helped many of them to acquire and master the skills of documentation and the observation of children.
- "I've learned that documentation is a treasure!";
- "I've learned how to transcribe and observe. This are skills I've acquired";
- "My writing ability improved considerably, my knowledge in transcribing grew and I've upgraded my ability to analyze the games";
- "I've learned to type faster";
- "Now, I know to observe children better".

These quotes show that the participants in the learning community gained mastery of the skills and came to understand the importance of documentation and observation in the field of education, in order to get acquainted with the world of the children.
However, this process also caused situations of lacking confidence, uncertainty and ambiguity, stemming from the absence of unequivocal decisions regarding ways to activate the children. The student-teachers expressed their desire to stay close to the familiar and known, to only do what is permissible, etc. They required great deal of support from their educational supervisors, due to prior educational and technical instructions in the process they had undergone. In order to meet their needs, we discussed topics that bothered them during their fieldwork, encouraging and supporting them. One of the ways to meet these needs was making the workshop programming more flexible.
The example below shows how the confidence of the student-teacher had deteriorated. She expected unequivocal answers from her Educational Supervisor about ways of working with the children and regarding which stories are suitable for each age group. In this case, this learner had a task-oriented involvement and her aim was to improve her mastery of the required task. In their answers, the Educational Supervisors focused on

the shared process of learning and its characteristics, explaining to the student-teachers that they, too, lack the answer to her question.

Example 6: Learning Workshop 2 (13/12/2002)

> **Student-teacher A:** Something doesn't work for me here. We're talking about a specific type of literature and generalizing for various levels of children. We're taking a type of literature that doesn't suit all the children.
> **Educational Supervisor A:** True, we're still searching for the 'right' literature. I think that the kindergarten should provide the whole story with the props.
> **Educational Supervisor B:** We're trying to investigate, but neither we, nor you, know which way will produce the results. We tried unfamiliar works, but sometimes we failed.
> **Student-teacher A:** The first conclusion is that maybe we should try familiar stories. Or we should continue [the story] to the end?
> **Educational Supervisor C:** That's why we meet, to derive conclusions from what we bring from the field.
> **Student-teacher C:** Perhaps we should continue testing unfamiliar texts, but less complicated ones.
> **Educational Supervisor D:** Maybe the conclusions would be different for the kindergarten and first and second grades.
> **Educational Supervisor D:** We should understand that this is research and the results are the study itself. Qualitative research is not meant to verify results, rather we're constantly generating hypotheses as the study evolves.

Emotional effects

In an interview conducted toward the end of the year, all the interviewees (12) mentioned their feelings during their participation in the study. Most of them described various positive emotions, such as: pleasure, belongingness, security, mutuality, group cohesiveness, satisfaction with the egalitarianism and pride. These feelings stemmed from the experience of being able to refer to various aspects within the framework of the learning community, in theoretical discussions and fieldwork experience alike.

The following are representative expressions made by learning-community participants during the workshops, indicating positive emotions:

Satisfaction with the egalitarianism

- "All the participants learn to the same extent. This gives a good feeling."
- "My opinions and theirs came from the same place."
- "We've tried and erred, just like the children did, and that's what I like most."
- "I was glad we continued to do here what the children did there."
- "I really liked the experience of team meetings with lecturers and senior students."
- "I felt satisfaction. I'm coming to contribute and being contributed to."
- "The distance was broken."

Belongingness and security

- "The mere fact of being able to work together with lecturers and be in the same position gives you confidence."
- "I was happy to attend the workshops. There, I saw that my mistakes weren't only mine. This empowered me."
- We all feel this way. One can experience, err and learn all the time from children about children."

Pride

- "I'm contributing. I succeeded in contributing to the discussion."

Intrinsic motivation vs. extrinsic motivation

During the course of this research and in all the learning frameworks in the community, we found no expressions of extrinsic motivation. We think that the likely explanation is that all the participants in the study and in the learning community volunteered to participate freely, without any coercion. From the very start of this cooperative project, there was a working atmosphere different from any with which we had been familiar. The partnership, involvement, curiosity and motivation to find answers to the questions coming

from the field, the interest in contents arising from the study, the experiences and meetings that were imbued with a desire to extend one's knowledge and share it with others – all these, apparently did not leave room for involvement characterized by an extrinsic orientation. It can be said that the participation in a learning community is both caused by intrinsic motivation and, at the same time, also generates it.

SUMMARY DISCUSSION

In the attempt to characterize the research process shared by educational supervisors and prospective kindergarten and elementary-school teachers, we have studied learning protocols in actual learning frameworks. The analyses of these protocols have taught us about the process we – the research participants - underwent and about the insights that were developed throughout this process.

Our findings indicate that the principles guiding the cooperative work process with the student-teachers and other participants in the learning community contributed to the nature of the learning. We did not determine, in advance, what would be relevant and what would not. We shared a process of deliberation, characterized by all the participants asking open and productive questions and ongoing dialogue. This was a dialogue between the findings and the theories and within the findings themselves. In fact, this was both an internal dialogue and a dialogue with active partners. In the wake of these dialogues, we derived our conclusions and determined new action methods. We tried to pass on the message that the ambiguity and uncertainty characteristic of the qualitative, reflective process are part of our learning evolution – for the student-teachers, educational supervisors and the in-training teachers. Critical thinking about the process provided us with the ability to see more than one perception of reality and, as a result, to reach a more complex perception of the examined situations and, thus, to gain greater knowledge and understanding. During the learning process in the workshops, the emphasis was placed on collaboration and egalitarianism, meant to facilitate the professional development of all the participants. The reciprocal ties were based on teamwork, mutual trust and open interpersonal communication.

Exposing the students to new research and professional terminology together with with actual fieldwork experience enabled them to develop an understanding of theoretical materials in light of practical action. Theoretical learning could be put to real use thanks to its immediate relevance to the fieldwork tasks. The learning frameworks in our research induced the student-teachers to become engaged in the research process and facilitated positive feelings and intrinsic motivation for further learning, through personal and professional empowerment.

As a teacher-training model, we have seen that an inquisitive learning community provides the learner with an experience different any he/she knew previously. Our learning community presented the student-teachers and educational supervisors a teaching perspective that can contribute to the improvement of their daily fieldwork, because, in this approach, the educational practitioners are a major valuable resource.

As for ourselves, as a final word -- if we may use metaphorical language – all we can say is that our learning community gradually 'composed' a polyphonic masterpiece, with its own unique harmony and characteristic sound.

betazzi@uol.com.br

Abstract: The objective of this study was to verify the relations between teaching self-efficacy and the burnout syndrome dimensions; also, the relations of these two constructs with personal and structural variables of the teaching work. 100 high school teachers from public schools participated in this investigation. Three instruments were used to collect data: one questionnaire and two scales, namely, a burnout scale and teaching self-efficacy scale. The results presented moderate average of teaching self-efficacy and average significant levels of Burnout in the three dimensions. The inverse correlations found between the two constructs were significant indicating the self-efficacy belief as a predictor of burnout. This investigation documents the multidimensionality of the teaching work. Results indicate the importance of debating the work conditions of high school teachers.

Keywords: Social Cognitive Theory, Teaching Self-Efficacy, Teaching Burnout; High School

INTRODUCTION

The teaching factor is always highlighted in studies as one of the most important ones in order to have changes made and evaluated in students learning. The teaching professional is asked to be more and more the protagonist of the daily complexity, which goes from his professional education, moving on to institutional disorganization to the violence against himself, including his low earnings. According to Campos (2005) 'there is the need of empowering the leading role of the teachers, to attend the learning needs of their students, to take part in changes and to contribute to transform the educational systems' (p.8).

The teacher working status, and how favorable it is or not for the practice of teaching has been the focus of questions and reflections. Pinto-Silva and Heloani (2009), commenting on research from Sguissardi&Silva Júnior (2009) in higher education institutions, and from Fortuna (2009) in state-run schools in the State of Rio de Janeiro, conclude that in the teaching current working configuration, there is a loss for health, prevailing on the damage to the socio-familiar life of this professional. Such damages are intimately related to the socio-institutional aspects, as heteronomous educational management, and intensification and the precariousness of work. The psychosocial aspects are also in bold, as the non-recognition of work (medium school teachers), competitiveness, the tiredness (professor-researcher) and the present conflicts in the educational institutions.

Esteve (2005) reinforcing his 1985 descriptive proposal about the two sides of the teaching activity, namely, the feeling well and feeling bad, affirms that the description of feeling bad is the one that is closest to the suffering reported by the teacher. He does not think to be so ill as to stop working, as with fever, headache or sore throat, but he feels ill and cannot identify why. The teacher starts to adopt some strategies to recover either personal or professional balance. The recurrent adoption of these strategies instead of not facing the real situations of feeling bad evolve to the precarious physical conditions that may result in such a bad physical state that makes it necessary to have the temporary or definite absence of the teaching activity. However, even without being away from the classroom, health loss for teaching activity and for the teacher itself are observed. The naturalization of the teachers' hard work conditions (Pinto-Silva and Heloani 2009) increases the possibilities of negative results during work, pushing even more these professionals away from teaching.

The study presented here was toward the investigation of the teacher´s illness, as well as the psychological variables involved. It seems to be relevant the search for comprehending the considerations presented above. The teacher is inserted in a working environment that builds and is built at the same time by him. For Bandura (1997) certain organizational conditions may weaken the beliefs in one´s working capacities and for this matter, occupational stress is not only a working problem. One of the core concepts of Social Cognitive

Theory, the self-efficacy beliefs, offer the foundation for human motivation, their well being and personal achievements, being this way, directly linked to the functioning of human self-regulatory capacities.

Bandura (1997) states that "perceived self-efficacy refers to the belief in one´s power to produce given levels of attainment" (p.382). It refers to one´s convictions about his skills to mobilize cognitive, motivational and behavioral functions to execute successfully a specific task in a given context. Since its formulation, it has been shown that self-efficacy beliefs predict behavior and determine if the perception of the lived events was cognitively represented and recovered in a benign way or emotionally disturbing. (BANDURA 1997). Undoubtedly, either the conditions of the environment, or the actions employed to attend the demand, the physiological conditions of the worker and self-efficacy beliefs interact and make it possible, or not, the resolution of the stressful condition. Self-efficacy has been related both with the reduction of the perception of a certain event as stressful and threatening and with health problems and illnesses in the teaching profession. Self-efficacy beliefs influence directly the perception of controllability of stressful events, resulting in the reaction to stress in a specific situation as the teaching work. (Bandura, 1986, 1997).

When thinking about the teaching function as one embedded in a labor organization, it is possible to consider what Bandura (1997) proposes when he states that the perception of personal efficacy in organizations determines if the behavior for coping stressful situations will be initiated, how much effort will be employed, and how long the worker will remain in the working situation. If one employee perceives himself with high self-efficacy, he will activate sufficient efforts to the execution of the tasks that, if well done, can lead to success. On the contrary, employees who perceive themselves with low self-efficacy tend to cease their efforts prematurely, fail in the task and develop some form of reaction.

One of the reactions to labor stress is the development of Burnout Syndrome, which is the combination of symptoms related to the activities developed by the worker, described by Fraudenberg (1974), involving, specially, the workers who developed tasks of care or with close relationship with people. The Burnout Syndrome has been characterized as the affective response to a continuous and long exposure to stressful work factors that generate emotional exhaustion, negative evaluation about oneself, depression and insensibility as to almost everything and everyone. To Carlotto and Palazzo (2006), it would be "the final stage of progressive attempts to deal with the stressful work factors (p.1023)." Physical fatigue and cognitive tiredness are also indicated as a result to prolonged exposition to stress related with work with close relationship with people.

The investigations on the Burnout Syndrome have been becoming diverse each day, either for the investigated population it the proposed instruments of measure, nevertheless, keeping as a common feature for the different segments, the relational aspects of the teaching. This condition increasingly exposes the teacher to stressors for a long period of time. For Reinhold (2004), in this situation, the educational professional makes use of maladapted coping strategies, leading to emotional, personal and professional exhaustion, worsening the feeling of inadequacy to the working position, negative attitudes and of distance with the students. The educational reforms and the implementation of guidelines also in the educational environment require from the professional of education persistence and innovation, besides a high cognitive engagement with the appropriate tasks. Given the current characteristics of the teaching function in all levels of instruction, including technical courses, with diverse kinds of students, this is presented as one of the potential professions to have this syndrome developed, once the social/relational dimension for the execution of the labor task is constant (Moreno-Jimenes & al 2002). Considered as a professional challenge, (Martinez & Salanova 2005), the teacher must have competencies and skills that go beyond the didactic and pedagogical matters which are the foundation of his education to be a teacher. The proximity and the behavior of care are emergent as to the teacher-student interaction, as well as the exhaustive amount of work (large classes, little Professional value, low earnings, adverse environmental conditions, violence). In the same fashion, the setting of goals related to the obtained results by the students is part of the planning of the teaching activities, and not meeting them would be another factor to be added in the possible vulnerability of this professional to Burnout (Labone 2004).

Some international and national studies have been made towards the search for relations between the Teaching Burnout Syndrome and cultural and psychological social variables. Beserra-Leite (2007) investigated the association of the social relations with the three dimensions of Burnout: physical and emotional exhaustion, depersonalization and reduced personal accomplishment. He found significant results of correlations between the variables. The results showed that the higher the support of peers, managers and family, the lower the indicative of burnout in the three dimensions. Weber (2004) investigated factors that affect the burnout in school psychologists (counselors) affirms that for Maslach and Leiter, the burnout has been considered more recently as a gradual progression within a continuum between engagement and disengagement from work. The lack of initial energy of the caregivers becomes exhaustion; the initial

involvement becomes cynicism, and their work efficacy becomes inefficacy. They also affirm that, the burnout can be attenuated by social support, autonomy in the work, and clear idea of the appropriate activities for the role. Martinez and Salanova (2005) identified significant relations between what the teacher realizes as obstacles and facilitators for the teaching practice and the burnout dimensions. Among the obstacles, you find the lack of support from peers and superiors, students who are undisciplined and little involved with school tasks, problems with the course material, difficulties with students´ parents.

The study made by Carlotto and Palazzo (2006), which investigated three hypotheses between possible associations of burnout with demographic and labor variables and factors of perceived stress, demonstrates the quest of these relations between the Teaching Burnout Syndrome and cultural and psychological social variables. An association between emotional exhaustion and the number of students and teaching working hours was found. This indicates that the higher the number of students, and the amount of teaching working hours, the higher tends to be the score for this dimension. The reduced personal accomplishment dimension of burnout was the one with highest mean scores, and it is analysed by the authors, inside a reference of organizational culture generating high expectations as to career, and considering how long have the teachers been working. Teachers who have been working for a longer time have higher scores in the personal accomplishment dimension, and the ones with great expectations with the teaching work also have higher levels of dissatisfaction because of the existing working conditions. Carlotto and Câmara (2007), searching a better understanding of the predictors of the Burnout Syndrome, investigated 563 teachers. The factors of the burnout scale: physical and emotional exhaustion, depersonalization and reduced personal accomplishment were considered dependent variables, and as independent variables: sex, age, number of siblings, amount of time of teaching experience, amount of time at school or university, weekly working hours, number of students/day, numbers of teaching, research and extension programs; dimensions of the features of the position, satisfaction with the earnings, critical psychological states, work results and satisfaction at work. Results yield to a predictor model of the emotional exhaustion dimension, having significant correlation with satisfaction with earnings (SAT-P) and age explaining 46,6% of the variability of the correlated dimension. The results for the depersonalization dimension had the variables: hours of research and the results of the performed teaching work detected as predictors and explain 57,8% of the variability.

Studies about the relation of these two constructs, teaching self-efficacy and the burnout syndrome have pointed to a wide range of correlated factors. Among these, there is the lack of professional accomplishment, peers and superiors support, interpersonal relationships, organizational climate, and also some personal aspects such as: sex and age of the participants, and the time of professional experience. The findings, supported in statistic analyses, raise important issues about the established relations and how much it is effectively possible to pursue, in a relational context, proposals of intervention. As an example, we can cite Friedman ´s (2003) work. She explains that school environmental stressors can be categorized in task stressors, organizational stressors and relational stressors, and that organizational stressors are the best predictors of high and low levels of burnout and of perception of self-efficacy in school principals. Continuing the studies about the relations between self-efficacy and burnout, she identified in 322 teachers in Israel that the perception of self-efficacy and burnout are inversely correlated, that is, the lower the sense of self-efficacy, the higher the perception of burnout. She also found as related factors for both constructs, the organizational matter and the interpersonal relationships as important variables for the prevision of Burnout in the three dimensions: physical and emotional exhaustion, depersonalization and reduced personal accomplishment. Salanova (2005) studying deeper the issue of obstacles and organizational facilitators of the teaching work, applied an adapted scale for a sample of teachers, made semi-structured group interviews to determine the facilitators and obstacles of the teaching work. These groups discussed the more frequent facilitators and obstacles, and eight items were perceived as stressors for the Spanish teachers. They are presented in order of importance: a) overload of work due to lack of time and excessive tasks, b) personal relationships that imply in emotional demand, either with students, parents, and the society, c) ambiguity in the role or the degree in which the teacher does not clearly have explicit the activities that he needs to realize, and what the school community expects from him, d) perception of contradictory instructions for the practice of the teaching work, e) lack of support from peers and the principal, f) lack of connection of the workmates to perform teamwork, g) students demotivation, apathy and indiscipline, h) problems with course material and failures in the structure or school facilities. Burnout, emotional exhaustion, cyniscism (depersonalization) and professional efficacy were measured with the Spanish version of MBI-GS adapted by Salanova & Schaufeli, 2000. Among the investigations of the constructs of self-efficacy and burnout in teachers in Brazil, we can mention Costa (2006) who speaking about Bandura´s Social Cognitive Theory and the concept of self-efficacy, presents a pilot research developed by her with 35 teachers using the 1999 Jerbeck and Bellico da Costa´s inventory. The results showed the presence of levels of burnout in these

teachers and negative correlation data between the presence of burnout and high perceived self-efficacy. Such findings, despite coming from a pilot study, point to the direction of increasing these investigations, because the relation between perceived self-efficacy and the development or not of the syndrome is noticeable.

METHOD

Participants
Data was collected in five state-run high schools of a city in South Minas Gerais-Brazil in the three periods between the months of March and December 2009. It happened after the approval of the Ethics Council of University of Taubaté with protocol number 351-08. 100 teachers participated, being them masculine and feminine, different ages, education and time of teaching. It was a prerequisite to be working as the responsible teacher for the subject that was being taught at the time of data collecting.

The characterization of the sample described above presented a general board of teachers between 40 to 49 years old, being 67% female, 44% with 20 years of teaching or more, 65% graduated in human arts and 90% graduated in private institutions. These teachers have 30 hours of more of weekly teaching. They work in public middle and high schools, with classes ranging from 20 to 34 students, and also from 35 to 50 students. As about school infrastructure, 65% of the participants considered it little sufficient for the teaching work. For the variables: self-perception of freedom of expression at the working place, professional accomplishment, administrative and peer support, and preparation for teaching, the sample presented the results displayed in Table 01.

Table 01. Sample distribution in self-perception variables. n=100

Self-perception	none	little	enough	much
Freedom of thought	2%	29%	48%	21%
Professional Accomplishment	7%	36%	43%	14%
Managers support	2%	30%	57%	11%
Peers support	2%	33%	51%	12%
Preparation for teaching	0%	9%	61%	30%

Description of the instruments
Given the objectives of the study, three instruments were used. One was Iaochite (2007) characterization questionnaire, which allowed access to relevant information from the participants for the study in an objective manner. The other two instruments were to Likert scales: Teaching Self-Efficacy Scale initially tested and validated with Physical Education Teachers in a study made by Polydoro et al in 2004, and the Teaching Burnout Scale CBP-R, preceded by the F*ree* Informed T*erm* of C*onsent*.

The internal consistency index of the scales is robust with confirmatory.factorial analysis

Data was individually or collectively gathered through printed instruments with the presence of a responsible person in public high schools. The average time for answering was 50 minutes. 100 instruments that were considered valid for the characterization of the sample were initially posted in the Excel Program, which allows data exportation to other statistic analysis programs, then the program SAS System for Windows (Statistical Analysis System), version 8.02.SAS Institute Inc, 1999-2001, Cary, NC, USA was used. . In order to analyze the relation among the numerical variables the Spearman correlation coefficient was used so as to evaluate the strength and direction of the correlation between two variables. The Mann-Whitney test was done to compare the variables of both groups, and the Kruskal-Wallis one was done to compare three or more groups due to the absence of normal distribution of the scores. To study the relation of the variables with the scores of the scales, it was used linear regression analysis, both univariate and multivariate, with Stepwise criterion of selection of variables. Linear regression permitted to estimate how a determined variable (Burnout) altered due to a change in a certain value on another one (Teaching Self-Efficacy – Teaching management and intentionality). The significance level adopted for the statistic tests was 5%, that is, $P<0.05$.

RESULTS

Observing the total averages in the Teaching Self-Efficacy Scale either in factor 1 and 2, or in the general scale, it was verified moderate levels of teaching self-efficacy with 71% of the participants with an average between 3 and 4,9 points. The highest average was 5,01 in the item belonging to teaching intentionality that is: *To what extent can you provide an alternative explanation or example when your students are confused?* This score has to do with the teacher´s perception to deal with factors related to his skills in giving lessons and teach content. The lowest average was 3,87 in another item belonging to teaching intentionality: *To what extent can you help parents to help their children to do well in school activities?* This item has to do with the teacher´s perception to deal with external factors of his teaching role.

It was observed in the Burnout Scale that the minimum and maximum scores ranged from 1 to 5 points, and the burnout item for the depersonalization dimension had 4 as its highest score and average of 1,75 for the item: *sometimes I tend to treat students as impersonal objects.* This dimension evaluates the impersonal relationship established with the students. The highest average was 4,02 for the item *Parents are involved in their children education*, which is inversely computed. Observing the average score in the CBP-R Burnout subscale we can see that factors EE (emotional exhaustion) with M=2,45 and FRP (lack of professional accomplishment) with M=2,64 presented higher scores than the factor for Depersonalization with M=1,86.

Spearman correlation (r) between the factors of the Teaching Self-Efficacy Scale, Teaching intentionality and Classroom Management, and the Burnout dimensions: physical and emotional exhaustion, depersonalization and reduced personal accomplishment, presented negative significant correlation between the two factors of the Teaching Self-Efficacy Scale and the three Burnout dimensions in the subscale CBP-R. The value (r= -0,39186) found in the score of correlation between total burnout (physical and emotional exhaustion, depersonalization and reduced personal accomplishment) and the total of the Teaching Self-Efficacy Scale (teaching intentionality and classroom management) is highlighted. In general, the scales were correlated in a moderate and significant way (p>0001).

Table 02 Correlations between the mean scores of the factors and the global score of TSEE and the Burnout Subscale of CBP-Rr

Teaching self-efficacy \Burnout		Emotional Exhaustion	Despersonalization	Lack of Professional accomplishment	Total Burnout

In the multivariate analysis, it was found higher scores of teaching intentionality, classroom management of the TSEE in the teachers with the highest perception of greater administrative support, and it was also found higher scores of lack of professional accomplishment of the Burnout Scale in the teachers with evaluation of lower administrative support. (Table 03)

Table. 03 Relations between the factors of the TSEE variables and Burnout and the administrative support variable

Administrative Support		N	MEAN	SD	MIN	MEDIAN	MAX	P-VALUE	**

** P-Value referring to the Kruskal-Wallis test to compare variables among 3 or more groups.

It was also verified the significant joint relation of Professional accomplishment and peers support with the score of lack of Professional of CBPR. The teachers with the highest scores of lack of professional accomplishment of CBPR are the ones with less personal accomplishment and less peer support in the characterization questionnaire. (Table 4)

Table 4 Multivariate Linear Regression Analysis for the score of lack of professional accomplishment of CBPR(n=100).

Selected Variables	Categories	Beta (SE)*	P-Value	Partial R^2
1. Professional Accomplishment	Nothing or Little (ref.)	---		
	Enough	-0.950 (0.128)	**<0.001**	
	Much	-1.190 (0.183)	**<0.001**	0.4653
2. Peers support	Nothing or Little (ref.)	---		
	Enough	-0.154 (0.128)	0.235	
	Much	-0.458 (0.198)	**0.023**	0.0290

* Beta: value of the estimate or angular coefficient (*slope*) in the regression line; SE: beta standard error. R^2: coefficient of determination. *Stepwise criteria of selection of variables*. R^2 Total: 0.4943. Intercepto (SE): 3.345 (0.107); P<0.001.

Table 5 shows the results of the multivariate linear regression analysis (with Stepwise criterion of selection of variables) to study the relations of the selected variables with the emotional exhaustion score of CBPR.

Table 5. Multivariate linear regression analysis for the emotional exhaustion score of CBPR (n=100).

Variable	Categories	Beta (SE)*	P-Value	R^2
Age (years)	<40 (ref.)	---		
	40-49	-0.197 (0.195)	0.315	
	≥50	-0.503 (0.219)	**0.024**	0.0525
Sex	Female (ref.)	---		
	Male	-0.127 (0.176)	0.472	0.0053
Time of teaching (years)	<10 (ref.)	---		
	10-19	0.182 (0.222)	0.413	
	≥20	-0.310 (0.213)	0.148	0.0523
Score of teaching Intentionality of TSEE	Continuous Variable	-0.285 (0.115)	**0.015**	0.0586
Score of classroom management of TSEE	Continuous Variable	-0.331 (0.118)	**0.006**	0.0738

* Beta: value of the estimate or angular coefficient (*slope*) in the regression line; SE: beta standard error. R^2: coefficient of determination (% of variability of the variable response explained by the independent variable). Ref: level of reference.

Through the results of the multivariate analysis, it is observed significant relation of the classroom management score of TSEE with the emotional exhaustion score of CBPR: The teachers with the highest score of emotional exhaustion score of CBPR are the ones with the lowest classroom management score of TSEE. Table 6 shows the results of the univariate and multivariate linear regression analysis (with Stepwise criterion of selection of variables) in order to study the relation of the variables of interest with the depersonalization score of CBPR.

Table 6. Multivariate linear regression analysis for depersonalization score CBPR (n=100).

Variable	Categories	Beta (SE)*	P-Value	R^2
Age (years)	<40 (ref.)	---		
	40-49	-0.329 (0.150)	**0.030**	
	≥50	-0.220 (0.168)	0.193	0.0476
Sex	Female (ref.)	---		
	Male	0.047 (0.135)	0.729	0.0012
Time of teaching (years)	<10 (ref.)	---

DISCUSSION

As a confirmation of the international studies, the results presented here also point to significant relations between personal factors (age, sex, perception of administrative and peers support, and professional accomplishment) and structural ones (school infrastructure) with the factors of teaching self-efficacy (teaching intentionality and classroom management) and the whole scale. Likewise, it was found relations between these factors and the burnout dimensions (physical and emotional exhaustion, depersonalization and reduced personal accomplishment) and the entire burnout scale. As discussed by Salanova (2005) and mentioned by Esteve (1994) these factors could be considered either as facilitators or obstacles to the teaching work, enabling a program of intervention with clear and objective indicators.

Regarding age range and time of teaching from the sample, the results point to a "finalization" of the teaching career. This happens in a context where more than half of the productive years (considering 55 as the retirement age, according to the Brazilian National Institute for Social Security – INSS) was employed working as a teacher and the perspective of retirement is more visible, with little or no possibility of changing the kind of work.

It was also verified that 65% of the teachers consider not the school structure not sufficient. This factor has to do with the conditions under which teaching is performed, that is, school facilities (classroom, desks, chairs, boards), the available materials (media resources, library), and the technical resources available inside the classroom and around the school. As suggested by the literature, we confirm the importance of the obstacles for teaching already discussed by Salanova (2005), adopting the definition made of these obstacles by Brow and Mitchell (1993). They say the obstacles are the environmental factors that have the capability to restrain the teachers adequate performance and have an important role in the teaching performance. Teachers with low scores in the evaluation of the structures and conditions of the school environment where they work, present high scores in the dimension of lack of professional accomplishment of the Burnout Scale CBP-R. According to Esteve (1995) these would be second order factors which also strongly affect the teacher´s motivation and engagement in his work even though being considered indirect factors. They are considered this way because they do not prevent the teacher from working, but the teacher feels unsatisfied, what may generate lack of professional accomplishment.

The perception of lack of administrative and peer support is demonstrated in this investigation as determinant factors for the teaching self-efficacy and for the burnout dimension of lack of professional accomplishment. Teachers with high scores for perception of administrative and peer support, also present higher scores for classroom management and teaching intentionality, which are the two factors of the Teaching Self-Efficacy Scale. The scores have significant statistic relation. Conversely, teachers who perceive little support either from the administration or their peers, present higher scores of lack of professional accomplishment of the Teaching Burnout Scale.

The analysis of the relations found between the factors of TSEE (classroom management and teaching intentionality) and the three dimensions of Burnout (physical and emotional exhaustion, depersonalization and reduced personal accomplishment) confirm the main hypothesis of this investigation, which was the existence of inverse correlation between these two constructs. The scores measured in the Linear Regression

Analysis for the dimensions of the Teaching Self-Efficacy Scale (TSEE) and the Burnout Scale (CBP-R) in Beta index allow the inference of dependence between them in an opposed direction. It was verified that the addition of a unit in the scores of teaching self-efficacy decreases the burnout dimensions.

CONSIDERATIONS

The results found in this research indicate the importance of the teachers´ beliefs about their professional activity. Different researchers have investigated these relations internationally, in the search of alternatives to explain a proposal of intervention that improves the quality of teaching and the quality of life of these teachers. Under the perspective of Bandura´s Social Cognitive Theory (1986,1997), consistent results have been found between the construct of self-efficacy and these contextual variables, and also relations with the three dimensions of the Teaching Burnout Syndrome.

The current teaching conditions, such as: number of students per classroom, workday, the teacher education, his roles, administration and peer support, teamwork, interpersonal relationships and student behavior are perceived by the teacher as extensively ample and with a low possibility of short term solutions. Besides the precarious conditions of earnings and career, we need to add the issue of violence against teachers widely shown by the media, the sudden structural changes made by arbitrary decisions as to the teaching methods, evaluation systems and the record of the activities. These occupational stressors demand active coping strategies that not happen, because the teachers usually adopt behaviors of avoidance and scape, as to pretend that nothing is happening, to let the time pass, to minimize the problem, to miss work, resulting in increased levels of emotional exhaustion, according to Carlotto (2008).

To Bandura (1997), the excess of work due to the constant need of educational updates and few opportunities to recycle may weaken the beliefs in the working capacities. Similarly, bad structured career plans that do not permit to visualize a real progression in the career, and the unbalance between the work life, and the personal life may also increase the adverse effects of low sense of efficacy for coping. When facing the academic stressors, the teachers with perceived high self-efficacy direct their efforts to solve the problems in a better way. They look at them as challenges and incentives, focusing its aspects in order to improve their own skills. On the contrary, teachers who have low self-efficacy, try to avoid academic problems and turn their efforts to relief emotional stress.

The present study documents the multidimensionality of the teaching function, its determinant relations and indicates the search for planned proposals for the increase of teaching self-efficacy as an instrument of change in the education scenario. Indeed, our teachers are more and more exposed to the occupational stressors that, if not approached in a definite way, will become chronic and have this professional ill with the development of the Burnout Syndrome, among other health problems. It is urgent the quest for possibilities of developing personal coping strategies that not only avoid getting sick, but also that strengthen the critical-evaluative capacities of these teachers. Bandura (2008) refers to an extensive program of investigations in which were verified new views about the role of perceived self-efficacy for education, for health promotion and prevention of diseases, demonstrating that such beliefs can be raised and strengthened generating personal and social changes. To Azzi (2010) social transformations are possible, and Social Cognitive Theory gives us the possibility of coping with everyday issues in a definite way.

Abstract: This work discusses the pedagogical mediations that are capable of favoring the process of initial reading and writing construction. It comes from the studies that have been developed by the group named Teacher Formation and Educational Practices in the Basic Education and College (GPFOPE), from the Federal University of Santa Maria (RS/BR), from the project Written Culture: methodological innovations in school. This study turns to issues that are related to the reading and writing appropriation, investigating the interactions and mediations that provide the advance on building hypothesis and conceptions developed by particular individuals in the literacy process. The studies that have been developed allow us to highlight the importance of the collaborative activities considering that they favor autonomy, self-organization and the social cognitive conflicts that are generated from the activities developed in a shared way. It is believed that the presented considerations are capable of contributing for the outlining of propositions that focus on overcoming the problematics which involve this thematic.

Keywords: literacy, collaborative activities, pedagogical mediations

INTRODUCTION

Many researches have been identifying problems within the children literacy processes and results in the Brazilian school context as indicated by the country's placement in the PISA105 (2006, 2010), in which Brazilians have been presenting low average scores to what concerns the reading and writing competences.

Under these perspectives, the problematic referring to the school failure in the literacy process has raised many attempts to alter this concerning picture. Public policies consubstantiated into programs, and curricular reformulations are sought by part of the Ministry of Education of the country. The schools manifest propositions of continuing formation for their teachers and partnerships with different community sectors in order to subsidize their teaching actions. Also, the Brazilian universities realize propositions that comprise the production of knowledge directed to the outlining of innovations in the literacy practice from the teaching/research and extension activities developed by themselves, as well as the increment in the actions of initial and continuing teachers' formation.

The work that has been developed by the group named Teacher Formation and Educational Practices in the Basic Education and College (GPFOPE) from the project *Written Culture: methodological innovations in school* inserts in the actions developed by the Federal University of Santa Maria in this direction. This project is constituted in a shared reflection space that involves the knowledge and the constructions of the literacy process, making it viable for the Municipal and State Education Systems school teachers, academics and other members of the research group to review, deepen and produce knowledge, allowing advancements in this knowledge field. Just as well, the possibility for the literacy classes students from the schools that participated in the research to be answered to their necessities, respecting the different learning paces and cognitive styles that are present in the classroom.

---

[105] PISA - *Program for International Student Assessment*, launched in 2000 with an assessment realized in 32 countries for students at the age of 15. It is a test realized every three years which evaluates competences in the areas of reading, mathematics and science. In the evaluation made in 2006 with 57 countries, Brazil placed in 49th. Even though the evaluation realized in 2009, released in 2010, revealed that the Brazilian education is improving, we still place in a bottom position: within a rank of 65 countries, we have the 53rd placement in Reading and Science and 57th in Mathematics.

The activities that are tied to this project refer to the follow-up of literacy classes in schools of the Municipal and State Education Systems from the Municipality of Santa Maria/Rio Grande do Sul (RS)/Brazil (BR); to the construction of diversified reading and writing strategies contemplating the cognitive differences of the learners and allowing a shared reflection space amongst the research group members106.

The methodology established for the research is that of qualitative nature, which consists in an ethnographic design based on participant observations and report analysis for following development of diversified activities together with the literacy teachers. According to André (2000), these observations are participants because the researcher has an interaction degree with the studied situation, affecting it and being affected by it. On the other hand, the analysis of the reports is working for the contextualization of the school reality facts, becoming a starting point for the studies based on theoretical sources, as well as for the necessary referrals for the development of the research.

In the ethnographic study there are other characteristics like the interaction between the researcher and his object of study, in which the researcher appears as an important mediating tool in the data collecting, making it possible, if necessary, the modification of techniques, the review of the methodology used in the research (André, 2000).

Thereby, the members of the GPFOPE have been working together with the schools so to understand that interactions and mediations are capable of providing the advancement in the construction of hypothesis and conceptions about the reading and writing of individuals in the literacy process, as well as expanding the findings and studies in this area.

We believe that such work requires an understanding on the ways of interactions that are capable of providing the advancement in the constructions both from the teachers and the children from the literacy classes. In this sense, the collaborative activities involving reading and writing have a preponderant role in these constructions, interfering upon the cognitive antecessors brought by the children and reverberating in the production of innovations in the educational practices (Bolzan, 1998, 2002, 2003, 2007a).

Next, we seek to provide conditions of pedagogical authorship and cognitive autonomy to the different individuals involved in the research from the methodological strategies produced and developed in the group, as well as enabling the study and discussion about which mediations and interactions can favor the advancement in the construction of hypothesis and conceptions upon the reading and writing.

THE LITERACY PRACTICES AND THE TEACHER EDUCATION: PUNCTUAL REFLECTIONS

The practices that refer to the reading and writing acquisition process can be described, at least until the 80's decade, by rotation: sometimes, the option for the synthesis principle, whereby literacy comes from the smaller units of language, the phonemes, the syllables, in direction to the larger units, the word, the sentence and the text; some other times, the option for the analysis principle, whereby literacy, on the contrary, comes from the larger units and meaning carriers: the word, the sentence, the text, in direction to the smaller units (Mortatti, 2006).

Under the perspective pointed out by Zaccur (1997), it is about ministering, drop by drop, minimal fractions of knowledge, assuming that the knowledge fragmentation means to facilitate learning. This way, teaching reading and writing sums up to a series of growing difficulties: first, isolated sounds in correspondence to graphical signs and, later, the disassembly and reassembly of words; words related to sentences, sentences putting paragraphs together and paragraphs integrating texts.

From the beginning of the 80's, such propositions have been systematically questioned mainly by the introduction of the constructivist thinking in Brazil, distributed by the Argentinian researcher Emilia Ferreiro and collaborators. The work of this author has brought a significant change in the assumptions and objectives in the literacy area, fundamentally altering the conception of the learning process once it has dislocated the axis of the discussions upon the teaching methods for the learning process of children, that is, it has positioned the debate no longer only on how to teach but mainly on how to learn.

These ideas have caused a true conceptual revolution as it has allowed identifying and explaining the process through which children appropriate themselves of the writing and, as a consequence of it, has suggested the conditions on which this process develops more adequately, revealing the fundamental role of an intense and diversified interaction of the child with the practices and real reading and writing materials so that the written language conceptualization process occurs.

---

106 Members of the research group are: teachers that act in classes of the first and second year of the Elementary School in the Private and Municipal System of Education from Santa Maria/RS, UFSM students from the undergraduate course in Pedagogy, from the Post-Graduation, master and doctorate in Education, as well as professionals from other related areas such as Speech Therapy, Psychology and Special Education.

Along with these ideas, the studies from Vygotski (1994, 2005) gain prominence in Brazil, fomenting the debate upon the necessity for rethinking the teaching of reading and writing because what is done is "We teach children how to draw letters and build words, but not the written language. This way, we emphasize the mechanics of reading what is written, which ends up obscuring the written language as such" (Vigotsky, 2007, p. 139, translation).

In this perspective, it is possible to indicate that the literacy practices have been constituting themselves from two great epistemological paradigms: the traditional paradigm of reading and writing teaching, fundamentally characterized by the formulation of "prescriptions" and "action procedures" that by describing the path to be taken in the literacy process with much objectivity lead to a pedagogical mediation based on the reproduction and execution of role models (Braggio, 1992). Just as well, the social constructivist paradigm which puts into question the standardization and unification models when it is suited in the idea of construction and re-elaboration of the social historical experiences, demanding the appropriation and re-elaboration of the knowledge and the deeds related to the reading and writing acquisition process (Powaczuk, 2008).

Thereby, the constructivist assumptions, once they foreground the idea of knowledge construction, restitute to the teacher the leading of their action, recognizing them as someone who is able to produce their pedagogical practice, providing subsidies for facing the singular classroom situations, making it possible to re-elaborate new theories, knowledge and deeds, from the analysis of the historical social contexts that occur in their literacy practice (Powaczuk, 2008).

We understand that this transformation process is slow and gradual which is constituted from a reflexive conciliating practice between the deed and the reflecting upon this deed, set in a double direction: the internalization of the principles and assumptions related to teaching literacy process and the exteriorization process, as the teacher needs to be capable of mobilizing the elements at their disposition for the construction of new possibilities for action.

The arguments of Isaia and Bolzan (2005) point to this direction when they affirm that the teaching acting implies in a process of the teachers' previous knowledge appropriation, pedagogical knowledge apprehended in the professional formation and their relationship with the pedagogical practice (the knowledge of the practice, as much as the knowledge mediated by the practice) developed in the teaching day-to-day through such an internalization process, leading to an active and transforming incorporation of the practices. There is a dialectical interaction between these pieces of knowledge. Not regarding a reproduction process but fundamentally a recombination of what has been experienced, translated into new ways of pedagogical intervention.

This process requires the self-reflecting capacity as intrinsic component upon the teaching deed and thought. The self-reflection process has to do with the comprehension and analysis of the realized ventures. It is when the individual puts himself into thinking about what is happening (reflection into action) or about what has happened (reflection upon the action) (Schön, 2000) with the objective of finding not only answers to the questions that he has made facing the found difficulties, but also to look for possible steps to be performed in order to achieve the intended purpose of his action.

However, in this confronting, not rarely the teachers are invaded with a feeling of pedagogical solitude which according to Isaia (2006) can be attributed to the feeling of helplessness of teachers facing the lack of dialogue and pedagogical knowledge shared to face the educational act.

In this direction, it is fundamental to consider as part of the literacy practice the viability of the space so that the teachers realize the shared reflection upon the deeds. According to Bolzan (2007b), the shared reflection process is fundamental to the teaching learning since it allows the building of ideas that are redesigned in shared way, creating an interaction web weaved as the participants of this process have the opportunity of confronting their points of view in relation to the knowledge and deeds that they produce daily, thus favoring the process of learning how to be a teacher.

THE BUILDING OF A COLLABORATIVE WORK BETWEEN THE SCHOOL AND THE UNIVERSITY: READING AND WRITING COLLABORATIVE ACTIVITIES

The work has been developed from the monitoring of the school reality through the analysis of classroom situations, which makes it possible to better understand in what way the teacher stands as a mediator of the pedagogical action, playing his role as a knowledge manager besides allowing to recognize and identify the ways of hypothesis construction and conceptions on reading and writing presented by the individuals in this process.

The members of the GPFOPE, together with the conductors of the classes, have developed and monitored the activities previously elaborated and collectively discussed in the study meetings. These activities took place

in six schools, five being municipal and one state level. From the monitored schools, five are situated in Santa Maria/RS and one in the municipality of Itaara/RS.

In order to boost the research, support groups have been constituted to each one of the schools that participate in the investigation, integrated by the members of the GPFOPE, together with the conductors of the classes, who have been developing reading and writing activities subsidized by the discussions and theoretical deepening realized in the study meetings.

The meetings are held fortnightly, sometimes taking place at the Federal University of Santa Maria (UFSM) – Education Center, sometimes at the schools that take part in this investigation thus becoming a space for shared reflection involving the knowledge and deeds about the literacy process, allowing the teachers of the schools from the Municipal and State Education Systems, academics and other members of the research group to review, deepen and produce knowledge in this area.

Initially, mappings of approaches to literacy in course were realized from the regent teachers' reports, as well as the diagnostic of the lecto-writing levels in the classes. For this, Ferreiro e Teberosky (1987) was chosen as reference in order to realize reading and writing testings. This initial contact was proposed as alternative to enable the creation of pedagogical strategies according to the necessities and interests of the groups that were followed, bearing in mind that such a work needs to be appropriated by the teachers and students involved in this process, searching for meaning and [re]contextualization that are proper and permanent to their knowledge deeds (Bolzan, 2005). Then, later, reading and writing activities were elaborated and developed in a collaborative way, having participated teachers and other members of the research group. This interaction process is characterized by the shared activity, jointly directed by the individuals that are involved in this process. Teachers, students and collaborators organize, disorganize, define and redefine the interactive process every each step. The basis for every cooperative activity is the joint action; there is negotiation, conflicts which establish a relationship web that composes the whole process (Bolzan, 2001).

For the foundation of this work, we have started from the referent studies to reading and writing acquisition developed by Ferreiro (1987, 2000, 2001a, 2001b, 2002), Teberosky (1997), Vygotsky (1994, 2005) and Salvador (1994). Also, the investigations developed by Bolzan (1998, 2001, 2002, 2005, 2007a, 2007b), which comprehend the reading and writing acquisition as a dynamic process in which each individual presents different cognitive styles, learning pace and ways of learning. Because of that, based on these researches, circuit activities proposals were elaborated.

This dynamic consists in the development of a set of activities which are realized simultaneously by the groups, having a particular thematic as articulator axis. The activities are arranged in each group after the mobilization for the theme in discussion from a support activity that can be, for instance, the reading of a story or a conversation within the big group, amongst other possibilities. At the moment of the distribution of the activities, pertinent explanations for their development are realized, providing the group with the autonomy to create or recreate rules according to their interests and experiences.

So that the circuit dynamic develops in an organized way, time is determined for the making of the activities in the group. The definition for such time requires a careful planning of the strategies to be developed once the activities progress must be in synchrony, in a way that the groups do not disperse. By the end or even during the activity development, each group receives a registration proposal, which is also flexible within the levels and hypothesis of reading and writing construction present among the children.

This way, these registrations seek to promote hypothesis confrontation, setting the different cognitive levels as upgraders of the collaborative activities that orientate the process of reading and writing construction. This situation also favors the remodeling of the teacher figure in front of this process, dismissing them from the center position in relation to their students' knowledge construction as the child starts to build their autonomy and recognize themselves as a potential informant (Bolzan, 2007a).

In so doing, the work realized with the schools allows us to confirm the relevance of the circuit dynamic as a way of pedagogical mediation. First, by the possibility of evidencing the distinct dynamic from what normally happens in the school day-to-day, generating confrontation and decentralization of the points of view and conceptions about the pedagogical mediations. In the studies realized by Bolzan (2002, 2003), these aspects are shown as resistance element from the teachers towards this kind of proposition as the centrality of the process is no longer their responsibility, beginning to collaboratively float among the students.

Making the activities in a cooperative way, creating room for the students to confront their hypothesis and assumptions with their peers, has evidenced the diversity as interchange situations and awareness upgrader, as well as enabling the remodeling of the teacher's role as the only informant to be consulted since each group integrant is stimulated to be recognized as potential informant.

In this process we have tried to highlight the importance of the teacher in the organization and mediation of the interactive processes that happen in the classroom environment, once that:

> (...) not all interactions are productive, the most productive ones are realized among individuals that are at different levels, though close in development. When the level difference among the individuals that interact is much great, the less advanced individual may ignore the conflict or not comprehend where the same is found. So that a convergence effectively results into a conflictive one, that is, the individual must have the intellectual tools that can make the conflict possible; they have to be capable of accomplishing the required adaptation for the elaboration of new coordinations (Lerner, 2000, p.109, translation)

We agree with Salvador (1994) when indicating that the teaching and learning activities cannot be seen as a series of fortunate encounters between the student and the learning content; it is necessary to consider the performance of the teacher, who is in charge of systematically plan these "encounters", thus being a true mediator and determining, through their interventions, the favoring or not of the process of building students' knowledge.

This way, the developed activities have been elaborated and thought of in the direction of "(…) creating an environment in which the child is called to express themselves, thus creating, exploring, building and also finding themselves being confronted with different points of view from theirs" Perret-Clermont (s/d *apud* Salvador, 1994, p.17, translation) and this has shown to be possible through the organization of different proposed games and recreation.

In relation to the ludic, as a limiting element of the activities, we highlight it as a fundamental element for the effective involvement in the proposed activities. The activities focused on exploring child imagination, from imaginary rides, collective production of stories, have evidenced the relevance of restituting the spontaneity and joyfulness to the teaching learning process.

Mello (2005) when problematizing the proposition of activities indicates that they need to consider the development of what constitutes the necessary basis for the longed acquisition. This implies that the work of the teacher should consider the main activity of each stage of the child's psychic development, which according to Leontiev (1984) refers to the activity whose development rules the most important changes in the psychic processes and in the child's personality psychological traits at certain point on their development. According to this same author, the instruction, in the narrow sense of the term, which develops first of all in the pre-scholar childhood, comes initially from playing, most precisely in the main activity of this development stage, that is, the child starts to learn when playing.

It is while playing that the child understands the social roles of people and the behavior patterns, once that it enables them to put themselves in someone else's place, taking over the behavior of the represented character, favoring the exercise of the child thought through assumptions and hypothesis. Such attitudes and capacities make the necessary foundations for the writing appropriation.

Therefore, we highlight the necessity of reviewing the time that is dedicated for these activities since they are many times seen as unproductive in schools, when, in reality, they are essential for constituting the basis for the writing acquisition (Mello, 2005).

CONCLUSIVE DIMENSIONS

From the work that has been realized, it was possible to identify changes both in the teachers and students positioning\posture throughout the work. Initially, the students have shown themselves to be insecure on how to proceed in the making of the activities collectively but gradually they have developed the notion of group work, thus being able to overcome the individualism that is characteristic from the initial phase, resulting into meaningful advancements in their productions.

To what concerns the teachers, initially, their collocations towards the propositions were limited to disbeliefs shown by their arguments and by not getting much involved with the activities elaboration as well as with the dynamics of the same. Many times they have used the occasion in which we were developing the activities to get other tasks done outside the classroom environment.

In this sense, we highlight that the interaction can many times be considered as disorder by the teachers of these schools, or simply a game with no pedagogical objective. Still, such work proposal can be understood as a tiring school activity once it requires from the teachers constant group reorganization, especially due to the loss of the disciplinary control of the group which they work with.

However, gradually we came to perceive alterations in the teachers attitude such as the interest by the games made, asking for keeping some of the materials in the classroom for later use, as well as by the involvement

that they started to have in the making of the strategies, proposing suggestions and, little by little, getting involved in the circuit dynamics, showing to be surprised at many times with the children advancing in their productions (Powaczuk, 2007).

When considering these ideas, it is important to highlight the words of Guskey (in Garcia, 1999) when indicating that the evidences of a positive change in the learning of students usually precede and they can be a pre-requirement so that there is a meaningful change in the teachers' beliefs and attitudes.

Thereby, even that the alterations noticed in the teachers' attitude are incipient they evidence the relevance of this work proposal together with the literacy classes. First, by the possibility of evidencing the distinct dynamic from what normally happens in the school day-to-day, generating confrontation and decentralization of the points of view and conceptions about the pedagogical mediations. Second, by the fact that it gives vent to discussion about the objectives and purposes of the didactic actions to be developed in the educational practice, once that it is necessary to establish shared goals. Last, by the possibility of crossing different glances at a particular didactical situation, generating a movement of thinking about and upon the collective and individual activity.

This way, we have evidenced that establishing spaces for shared reflection based upon the pedagogical deed is indispensable for the production of innovations in the educational practices as it enables the activation of the teaching thinking. According to Bolzan (2002), the possibility of putting thoughts into words allows the teacher to become aware of the comprehension or not about the themes in discussion, generating a questioning attitude and, consequently, making them reflective of their pedagogical knowledge and deeds, thus favoring the process of remodeling the educational practices.

It is kwon that there is still a long way to run so that there is an effective modification of the pedagogical practices in the literacy process. Therefore, this is a challenge that needs to be taken collectively, from the establishment of teaching spaces, which involve personal and institutional effort that are concretely developed, oriented to the remodeling of the knowledge and deeds tangled in the teaching literacy performance. Believing in this possibility makes us continue to accept this challenge: developing collaborative and diversified reading and writing activities in the circuit dynamics in literacy classes.

Abstract: Understanding the processes related to teaching learning has been the highlight of studies that are developed by the Teacher Formation and Education Practices group: Basic Education and College (GPFOPE), which is linked to the Research line: Formation, Knowledge and Professional Developing from the Federal University of Santa Maria/RS/BR Post-Graduation in Education Program. The research aims at understanding teaching learning conceptions and their repercussion in the building of professorshipness, longing to cooperate with initial and continued teaching development. The carried out research allows to identify teaching learning based on the ongoing developing process, considering the attributes of each professional, as well as the demands of the teaching context, for teaching and learning presuppose having their own paths, which depend on the experiences of being a teacher/professor and on their personal knowledge, apart from their needs and interests, allowing thus this individual to reflect and reconstruct experiences and knowledge which belong to the specificity of their working field.

Keywords: teaching learning, professorshipness, formation processes

INTRODUCTION

The discussion proposed here focuses in the processes surrounding teaching learning, highlighting the relations which surround knowledge domain (scientific knowledge) and know-how domain (working knowledge). It starts from studies developed by the Teacher Formation and Education Practices group: Basic Education and College (GPFOPE) on the research basis of Teaching learning and educational processes: constructive movements of professorshipness in basic and higher education set in the Research line: Formation, Knowledge and Professional Development from the Federal University of Santa Maria/RS/BR Post-Graduation in Education Program.

This study carries out a qualitative-narrative investigation dynamics aimed at understanding the movements produced in teaching learning, both of the teacher who is in charge of the basic education and of the professor of higher education directing us to deepen the subject matters which represent the building of being a teacher/professor.

The studies of Bolzan (2001, 2002, 2007\2008, 2008, 2010); Bolzan and Isaia (2006; 2007); Isaia and Bolzan (2004; 2005; 2007); Vygotski (1993 1994); Davidov and Markova, (1987); Leontiev (1988 1984); Pereira (2000); Ferry (2004), Zeichner (1993), have marked out the routes of our reflection on the complex path teachers/professors go through along their professorshipness production.

Following this idea, the research held by this group starts from a qualitative-narrative approach, reasoned on the teachers/professors voices/ idioms/ speeches about their teaching conceptions and their learning to be a teacher/professor all through their professional education on duty.

Therefore, the investigations take into consideration the shared building processes, as well as the participant individuals social cultural reality, from teachers/professors' discursive/narrative activity analysis making it possible to have an understanding of teachers'/professors' activities, unclosing the subjectivity/objectivity of social relations one can have in teaching (Bolzan, 2007).

The participant individuals of this investigation are active professors of a public university Pedagogy Course, of an education advising center, and of working teachers from public and private teaching system schools, located in the city of Santa Maria-RS, summing up 32 individuals (13 Basic Education teachers) (E.B) and 19 professors from higher education Centers (IES)).

As investigation tools, semi-structured interviews are used, from which teachers/professors are invited to tell situations, facts and stories about their personal and professional paths that contribute to the understanding of the building knowledge process on teaching and its relation with professorshipness, specifying the fundamental movements in this formation process. In this manner, it is believed that the relevance of this

research consists of the possibility of thinking about initial and continued education, not only by the participants of this study, but also by undergraduate students and working teachers/professors. The possibility of reflecting on the theoretical bases built throughout their paths of being a teacher/professor makes it possible to create new and distinct configurations in their actions. It was therefore confirmed that stimulating teaching reflection enables one to produce from his/her own self, resulting in the process of learning about teaching.

THE BUILDING OF PROFESSORSHIPNESS

The studies developed up to here have made it possible to comprehend professorshipness (Oliveira, 2003; Bolzan & Isaia, 2006, 2007; Isaia & Bolzan, 2004, 2005, 2007) related to the subject-teacher's/professor's change movements all through his/her education path, regarding the teacher's/professor's actions and operations, considering

> […] not only the domain of knowledge, education, activities in a certain field, but also the teacher's sensitiveness as a person and professional in terms of attitude and values, having the reflection as an intrinsic component to the process of teaching, learning, educating him/herself and, consequently, developing professionally (Isaia & Bolzan, 2005, p.03).

The comprehension of movements produced in the teaching building implies the consideration on education as a permanent process in the production of being a teacher/professor, in which teachers/professors, on the basis of their own individual and shared experiences, build new strategies, new means of actions and of taking the professional field in a personal development dynamics. It is a question of the process of subjecting oneself *to be able to* (FERRY, 2004) being that alternatives the individual finds to accomplish certain assignments to do a particular task, job, profession, getting away from the educational conception as something to be absorbed, come from the outside, external to the subject, since,

> […] education is not received. Nothing can educate the other. It is not possible to talk about an educator and an educated. Talking about an educator, and about an educated is to affirm that there is and active pole, the educator, and a passive pole, the one who is educated. […] the individual gets educated only by his/her own meas (Ferry, 2004, p.54).

These matters are related to the processes involved in **teaching learning**, as the teaching education is directly related to how the individual subjects him/herself as a learner. It is not about considering education as an independent or autonomous process, but perceiving the personal component, in highlights, in its dynamics, in which the teacher/professor is the ultimately responsible for the motivation and development of the process.

It is highlighted in teaching narratives the comprehension of incompleteness and the search for education continuity as basic elements in this process. The latter, in turn, puts into action distinct ways of teaching development based on peculiarities gotten from different educational practices which are used by the professor throughout his/her educational path. The narratives which follow evidence these aspects:

> *My style is more reflexive I entered philosophy by the philosophy and not by its teaching, do I myself more reflection then, it depends on each one, there are people that want things to be faster more urgent I like things to go slow elaborating being elaborated they go on sitting how you say finding out meanings establishing relations it can be a bit slow but I think it has more quality otherwise you end up reproducing what others say (professor CO-ES)*
> *So I think that this way, I have this way of being so [...] how can I say [...] I am not very systematic in my studies, I know what I want to study, I need some…but I am not one of those who sits for five hours reading the same book about the same theme. I like to read a little, talk about the subject with different people, verbalize it, and when I say different people it is people from different social classes, from different levels of education. (professor CE- ES)*

As it is evidenced in teaching narratives, personal dimension defines the distinct ways of teaching learning, making it possible to indicate this process to be linked to the demands of life, of profession and of established interactive and mediatory processes, being thus the personal and professional paths defining factors to a teacher's/professor's ways of production (Isaia & Bolzan, 2005).

In this process, however, the **gain of awareness** is highlighted on ways of thinking and conducting teaching practice, which are intrinsically linked to the understanding of teachers' /professors' roles and of the

responsibility they carry in the educational context they work. It is characterized by the teacher'/professors' access, by his/her willing to elaborate and re-elaborate his/her practical theoretical constructs, putting him/herself as subject of this educational process. The narratives which follow specify these aspects:

Well, if I am to be a higher education professor, what do I need? Theoretical deepening. I need more than anyone to have knowledge of all this theoretical field with which I am going to work, so that I can have the bridge between this student's culturally built knowledge and the academically built knowledge. So I needed to know very well both kind of knowledge in order to be able to make this bridge for I believe my role is to make the bridge (teacher RO-ES).

To work with teacher's education demands to know the subjects' reality in this process. The experience in basic education has always been a reference to think the learning of being a teacher be that of subjects in development and we ourselves as educators. (AD-ES)

[...] my greatest concern is to create a pleasant environment at school so that these kids wouldn't get tired so that they would really want to go to school, because it is not easy at all to spend whole morning and whole afternoon in an environment if this environment is not beautiful, cozy and fun, because after all, they are kids, they are individuals craving for playing [...]. I think there is a necessity of you to follow certain school subjects, curriculum, in the sense that the school has a prime role that if it is not the school to teach certain concepts, maybe there will be no other place of learning for the kid. And when this is very well systematized, it helps the teacher a lot in his/her lesson plans and also in the development of the classes. (SI-EB)

In this perspective, **teaching learning** is enhanced when the subject teacher/professor is capable of separating aspects in his/her activity, noticing relation among them; by the ability of modifying one activity component and, finally, by the ability of differentiating the means and activity procedures and the selection guided to an end during the activity realization, that is, the ability of the current activity auto-regulation (Davidov & Márkova, 1987, p. 188). As it is evidenced in the following narratives:

[...] Yes, you learn more. It is interesting because one can notice the growth, because that which you didn´t know now you know, what you don´t know now are other matters. So it becomes interesting. This I find good, I like being able to see myself in the walk, how do I say, because this way we see ourselves this I didn´t know, now I know, now what I don´t know are other matters. (AD/ ES).

I learn with challenges, for example, inclusion [...] I didn´t want inclusion, why? First I didn´t feel prepared   [...] I never appreciated poorly made work, then I took a nearly 200-hour course on inclusion on Fridays and Saturdays [...]   we have to invest [...] We don´t have financial return, but we do have learning return [...] I was totally unprepared, then I decided to read and study, what autism is, what down is and when we see theory without having the practice it is one thing, but when you have the practice and see yourself searching for theory, then it is different [...] (MA – EB)

This auto-regulation process implies becoming aware of ways of production in teaching, demanding from the teacher/professor to refine the elements involved in his/her education. As the teachers/professors report in their narratives the possibility of seeing themselves on the way is an indispensable condition for their teaching qualification, as it makes it possible to recognize the ways already walked through, as well as it open possibilities to new paths to be explored.

These aspects make it possible to indicate for an elaboration of a **study teaching activity** which consists of getting involved when working as a teacher/professor and, mainly, the mobilization of the subjects in their search for qualification as a strategy capable of collaborating to the advance in the pedagogical work.

This process showed to be linked to the job the teacher/professor does in his/her **pedagogical work** which is about the processes involved in the teaching practice in action, the ways of organization and reorganization in the strategic didactics. It implies reflection and the constant redimensioning on pedagogical actions developed by the teachers in the perspective of providing autonomy and the mobilization to search knowledge (Bolzan, 2008). These aspects can be noticed in the teachers'/professors' narratives

Take a look at their background luggage [...] and you want to teach them. And they come up with something else and then you have to stop and see [...] I think that what I am teaching is not so interesting. And then I stop and think, so we are always learning, and you learn with kids, right.

They come with much knowledge, even if it is some popular knowledge [...], but they have some knowledge and you cannot ignore that [...] (LU-EB)

The aspects mentioned in teaching narratives make it possible to indicate the emergency of conflicts in the **pedagogical work** organization, working as generator elements of a reflexive attitude from the teacher, and therefore capable of starting the **study teaching activity**. The challenge of being in charge of new issues concerning the developing teaching action and the necessity of creating alternatives, strategies and ways of organization to the problematic experienced in the performance of this profession, guide the teacher/professor to a reflection process and re-elaboration of what he/she has produced.
The professor's narrative reveals this process as propeller in building new learning:

[...] suddenly you review your ideas [...] they will form a new element, of course, evidently, you are arguing with what you have taken possession of, isn´t it?   [...] you establish this internal dialog, so I think this reflection is the one process which basically feeds the teacher. (Professor CO – ES)

This "internal dialog", present at the teaching speech, highlights the polyphony which composes the reflexive process of the individual that questions about his/her work. In such dynamics, it is perceived that this exercise ends up in rethinking of ideas and in changing the way to think the teaching practice itself, longing to make it better (Bolzan, Powaczuk, Fighera, Santos & Rossetto, 2010)
The studies done make it possible to indicate this process to be related to what we denominate **pedagogical alternation movements**, which are characterized as transitional spaces/times between working (teaching practice) and producing knowledge about this work (educational action), demanding from the teacher/professor to keep a certain distance which enables him/her to see his/her action as analysis object (Ferry, 2004).
This process is evidenced in the teaching narratives resulting from dissatisfaction between individuals who long to do and the ones who actually do, besides the desire of obtaining more control over the pedagogical activity. These aspects can be noticed in the following narrative:

Thus this way, I actually found it difficult to work with Information Systems [...] To start with it is many men, something which is totally different in Pedagogy. So they come in, open their laptops and there you are talking and questioning, trying to establish a dialog. I did it on purpose [...} to keep talking about evaluations, no when I talk about evaluations they will correspond. Nothing. Correspond? [...] So it is interesting to work with other courses so that we get to know other students' profiles and ours too. (GA/ES)

The possibility of seeing yourself through the walk and the attitude related to the gain of awareness on the ways of teaching production present in the narrative of the professor **GA** is an indispensable factor to assume one specific action in this direction, as it is made possible to recognize the paths already walked through, as well as it opens perspectives to new routes to be explored.
It is a fact that teachers/professors in their daily work, more and more, find themselves in complex situations of all kinds, be them working with basic education or higher education. Besides the challenge of dealing with a varied public, there are also the institution organizational tensions, relations of power among the teachers, charging regarding productivity and professional performance, generating, not rarely, the feeling of solitude[107] and pedagogical anguish[108](Bolzan, Powaczuk, Fighera, Santos & Rossetto (2010). The teachers' sayings illustrates these strains:

Today, in terms of academical level there is a kind of culture on academic performance there is a kind of productiveness I think it is also competitiveness so people loose the greatest references and their partner becomes a competitor, in all circumstances (Professor CO- ES).

---

[107] According to Isaia (2006) pedagogical solitude refers to the feeling of abandonment teachers have face the absence of interlocution and pedagogical knowledge shared in order to face the educational act (p.373).
[108] According to Isaia (2006) the Pedagogical anguish is a feeling developed by teachers because they are aware of the necessity to transform their practices, but they do not know which way to follow. They feel under pressure by the demands of their work, mainly in terms of institutional charging, be that by their titles, production or by pedagogical competence (p. 373).

[...] because teaching does not involve only the teaching classes matter, it involves whatever else from the university, institution in which I am... so, from the relations that are there, from power plays that are constituted, from the organizations, both from my class, and ... finally, from my work in general, so it is necessary to adapt many things (Professora AL- ES)

These strains demand from the professor an attitude of personal balance and serenity which allows him/her to resist and find possible alternatives to realize their work. In teaching narratives, different routing regarding these aspects are noticed, characterizing distinct ways of facing situations, which go on being elaborated and rebuilt throughout the events the individual goes through. As the voices/sayings from AC and LU exemplify:

[...] I think that maybe because I feel as a teacher and very confident of what I do, I have no fear of the challenges my working field can bring to me with the people I will have to deal with (Professora AC- ES).
I did exactly what good part of the teachers who are in a managerial position do, they void their lives and start virtually living inside the university. We all do that. They spend much longer here and then it seems that the university is every thing and family is second plan [...] I made an option I want life, I don´t want to let this institution to kill me because at the most they will send me a funeral wreath (Professora LU- ES)

These matters link us to what Souza (2009) denominates resilience. This author highlights this concept to be related to a differential and evolutive component, which "would explain why certain individuals in identical situations deal with adversity in a more adequate way than others" (Souza, 2009, p.79). An ability susceptible of evoluting through the activation of certain mediations, which happen in the different contexts the individuals are inserted. The narrative of professor AC illustrates this process:

[...] I suddenly found myself in higher education with adult individuals, who questioned much more and there are other kinds of challenges and questionings and arguments and all that, right? I did not fell right there without having a previous experience [...] so I had been through other experiments that, I believe so gave me basis for these challenges (Professora AC- ES)

These considerations allow us to indicate that **teaching learning** is related to the development of this ability, involving the building and rebuilding of the experiences an individual brings along him/herself, producing new senses and meanings for the experiences they have. This process is about the ability in a teacher/professor who, however in hard challenging unfavorable situations, is capable of dealing with the situation, overcoming them and using them for his/her personal and professional development. This way, related **teaching resilience** is named:

[...] the ability of a teaching individual's internal reorganization face the challenges and conflicts evidenced both in the organization of pedagogical work and in the teaching study activity in which he/she gets involved. It presupposes the facing of hard situations lived in the classroom, implying the surpassing of conflicts come from the appropriation of new ways of knowing and doing teaching (Bolzan, 2010).

A process which can make viable the change and the [re]signification in the ways of being a professor, understanding new horizons for the teaching activity. It is observed that the sharing between pairs emerge as an important element in this process. Such consideration can be evidenced in the narrative that follows:

*Let´s rethink this which is bad! It is interesting because we go on constituting ourselves, learning, changing, seeing ourselves some other way. Because we see ourselves one way, then there is somebody who says **no**, seeing you some other way, it is important to us this shift, so that we qualify (Professora GA- ES).*

The done studies put into evidence the sharing between pairs as an important tool in this process. According to Bolzan (2008), the shared reflection process is fundamental allowing the building of ideologies and conceptions which go on re-designing themselves, and thus creating a net of interactions which is produced as the participants of this process have the opportunity of confronting their points of views regarding the knowledge and work they produce daily, favoring then the process of learning to be a teacher/professor.

These aspects are evident in both the basic education teachers' narratives and in the IES professors' voices. However, there are recurring manifestations in the Basic Education teachers' narratives, which make it possible to infer the interaction between pairs as a highlighted element in the process of reorganization in the teachers' teaching practices in this level of education.

It is also pointed out that the basic education teacher manifests his/her teaching reorganization based on elements present in their daily teaching, that is, it is the school floor, the space capable of providing the necessary elements for his/her teaching production, being the interactive processes established with their co-workers and students, defining factors in the way they work in the teaching activity. The narratives which follow show these aspects.

> *[...] I worked this way for years until I realized it was not like this [...] you see with people what works out, somebody comes to you and says "maybe you should do like this." So you dare to do different (TA-EB)*
>
> *[...] So I saw it was working. And that is how I kept on going each year thinking about what I could change, what other alternatives I could use to fill my job, I went on searching, finding alternatives (...) it is in your daily life, in your dedication, your involvement and in the expectations that I create with them and we try to create, to idealize together, it is not alone, it is together, together (SI-EB)*

Regarding higher education professors the sharing is highlighted, however, it is not as frequent as it is expected. It is highlighted in the IES working professors' narratives distinctive devices in the production of spaces/times of pedagogical alternateness and teaching resilience, which refer to the theoretical deepening, the research, as well as the written productions resulting from this process. The narratives which follow illustrate these aspects:

> *[...] so suddenly you review your ideas, your ideas will form a new element of course, obviously, you are arguing with what you have taken possession of, isn´t it, or about what you have interpreted over what you have appropriate, so you establish this internal dialog. I think this reflection is the process of basic feeding for the teacher as you reflect and evidently new questions come up and that is what guides you to search new information or read again this or that author, go back to discussing this or that; so I think reflection is a fundamental element that is what you learn [...] when you are reflecting (RO-ES)*
>
> *[...] I usually write; I've always had the systematic habit of writing; I think before entering university ever since 1965 I used to write systematically every day and to keep some discipline [...] it is some kind of reflection that you put into a paper; then you can dialogue with other people that agree, disagree; or write to newspaper, this is they way I write. So this is a way, if you don´t keep it only to yourself you have to share, right?   (VA-ES).*

Through the voices of the higher education professors we can check that sharing emerges from dialogue with different authors, with supposed readers of their productions, and also with themselves, enabling us to indicate a differentiated teaching production process based on an individualized and auto-guided perspective. Regarding individual perspective, we believe this situation comes from a strong binding this space of teaching working has with research. That is, the fact that an individual is a good researcher would be some guarantee of his/her success in the teaching performance. These aspects are evident both in what is referent to the legislation that normalizes the entrance to the higher teaching career and in the assessment and productivity criteria in higher education. This conception, in turn, has provoked by the institution the lack of commitment with continued education and with its professionals' teaching role, leaving this responsibility of education to each one individually. Thus, the spaces of sharing focused on professional education, or even the discussion of aspects which belong to the teaching practice, in a more systematic way, are restrict in the IES (Powaczuk, Santos & Bolzan, 2010).

Concerning auto-directing, this process can be understood as resulting from an intense elaboration exercise about the professor's working field, having in mind that these professionals, besides the matters that surpass the classroom daily routine, have the responsibility of scientific production in the field they work. The professor when mentioning this teaching working field emphasizes:

> *[...] I felt the necessity of deepening even more the theoretical field. And I ended up emerging through the curriculum field where there is an intersection of public politics and the epistemological issue and I end up searching for the researcher profile. A researcher profile is not about the one who*

researches for the sake of the research only, but about the one who develops the ability of a researcher […] which is this sensibility, the ability to observe, the transparency of what he sees and not a misleading idea of if, which is to have a serious theoretical analysis not only with the idea of reviewing it, but of having the critics also showing what can be done (...) (AR-ES)

In this way, when analyzing the moves of teaching building and rebuilding which configure in the two levels of education, the production of different mechanisms is highlighted, characterizing distinct professorial drawings which get built from various sources, spaces/times of alternation and ways of facing the situations in the teaching daily routine. Thereby, the configuration of this dynamics gets teachers involved in a reflexive process which demands regaining teaching movements, being this process basis for teachers to build and legitimate new knowledge regarding the teaching activity.

CONCLUSIVE DIMENSIONS
The reflections and discussions established in the research development make it possible to indicate professorshipness to be constituted from movements which surpass the teaching production, having reflection as intrinsic component to the process of teaching, learning, getting educated and, consequently, developing professionally. as a result, three elements constitute as guidelines in this process: teaching learning, pedagogical work, the study teaching activity (Bolzan, 2008).

Teaching learning is characterized by the gain of awareness process on constructive movements that individuals in the professionalization process produce to learn and teach. We highlight in this group of elements the understanding of incompleteness and the search for education continuity revealed by the gain of awareness that in this process we are educators and learners simultaneously. This way, the emphasis on the teaching practice is based on experiences which unfold from reflections and interactions established through events and facts reproduced in the pedagogical relation.

Regarding **pedagogical work** it touches upon processes involved in the teaching practice in operation, involving ways of organization and reorganization of didactic strategies. It implies reflection and the constant redimensioning of pedagogical actions developed by the teachers/professors with the objective of promoting autonomy and the mobilization to search knowledge (Bolzan, 2008). And, **the study teaching activity** involves built educational movements, which emerge as demands of the teaching profession. The study teaching activity consists of getting involved with doing the teaching and, mainly, the mobilization of the individuals to search qualification as a strategy capable of collaborating to the pedagogical work progress.

This way, we identified from our studies distinct professorial types being produced from a peculiar composition which involves the three elements mentioned above. As aspects which boost this composition we identified the **pedagogical alternateness** movements and **teaching resilience** (Bolzan, 2010).

When we highlight these movements we emphasize teaching learning related to the own teaching-in-operation retake processes, having the teacher/professor to face different circumstances and challenges which are established in the daily teaching. This process shows the effort of a teacher/professor guided to go beyond and achieve his/her own way, outlining singular contours of teaching learning. This singular learning gets amplified as the teachers/professors, in interactive situations, discuss and re-elaborate their capacities of facing situations with their pairs, so the sharing spaces emerge as a highlighted element in teaching learning.

Therefore, in an effort of understanding the complexity which involves the dynamics of teaching and learning we judged that these elements are capable of qualifying the educational processes as an investment in interpersonal relations and in the collaborative work.

286 - Academic Self-Efficacy and Learning and Study Strategies: Brazilian Students´ Perceptions

Roberta Gurgel Azzi[1], Daniela Couto Guerreiro Casanova[2], Marilda Aparecida Dantas[3], and Ana Cecília de Medeiros Maciel[4]

Universidade Estadual de Campinas

[1]betazzi@uol.com.br, [2]danielaguerreiro@yahoo.com.br; [3]marildapsico@uol.com.br; [4]nani@yazigi.com

Abstract: The objective of this study was to analyze the correlations between Academic Self-Efficacy and the use of Learning and Study Strategies of Brazilian high school students, considering the specific characteristics of each grade, each period, and the conditions about students who also work or not. 534 high school students from nine public schools participated in this research. The following instruments were used: High School Students Academic Self-Efficacy Scale and Learning and Study Strategies Inventory, having used its dimension named Information Processing. Results presented positive, significant and moderate correlation between Academic Self-Efficacy and Learning and Study Strategies. The correlations showed a difference of intensity when considering the school grades, periods and whether the students also worked or not. For the Brazilian sample, Academic Self-Efficacy is associated with the prediction of actions towards the use of Learning and Study Strategies. Important educational implications shall be discussed.

Key-words: Self-Efficacy; Study Strategies, High School, Motivation

INTRODUCTION

The belief of academic self-efficacy has been identified as a predictor of desirable actions to promote school learning. Studies have demonstrated that students with high perception of academic efficacy are more cognitively engaged during classes, and this fact helps them to develop educational competencies. They are also more persistent against school challenges, besides demonstrating higher availability for tasks related to studying even when there are other social activities to do. However, the belief of academic self-efficacy involves something bigger than the perception that effort can conduct to success. It encompasses the judgments about one´s knowledge, one´s capabilities, the strategies one dominates, and the way one uses them in order to manage the stress related to the educational tasks, affecting the students' aspirations and their levels of interest in intellectual subjects, mediating, thus, the motivation to learn. (Bandura, 1993, 1995; Zimmerman, 1995).

High levels of academic self-efficacy have also been associated to the capacity of learning to learn, so necessary these days. The setting of learning objectives, self-monitoring and self-evaluation are actions that guide the process of learning how to learn, and these processes enable the self-judgment about one´s understanding regarding the learning that occurred. Students who perceive themselves more capable tend to understand that skills can be built, and they self-regulate their own process of learning. To do so, they select and use diverse learning strategies, trying to find the most appropriate one for each kind of activity to be developed (Bandura, 1993, 1995; Zimmerman, 1995).

Metacognitive strategies are fundamental to self-regulated learning, because they provide the selection of the appropriate strategies, test the individual comprehension about one´s own knowledge, allow the corrections of the individual weaknesses and the perception of the cognitive strategies (Boruchovitch, 2004). There are diverse strategies which are characterized by different types due to the cognitive resource applied by the student, especially the ones denominated information processing (Boruchovitch, 1999). Pozo (1996) defined that study strategies refer to the means or ways the students use to learn or as a sequence of planned activities performed by the subject in order to learn something.

In the research made by Bartalo (2006) the verification of the use of the information processing strategy by the students consisted of evaluating the "use of imagery and verbal elaboration, monitoring of comprehension and reasoning", and also, "the building of bridges between what the student already knows and what he is trying to learn and remember". This has as steps the "processes of acquisition, retention and future application of new knowledge and information" (p.75). The operational way these study strategies can be performed requires from the student the use of meaningful and organized means, for example, to

paraphrase and summarize texts, or even to elaborate analogies, notes and schemes, as well as the use of analytical, inferential and synthetic thinking.

Valle and colleagues (2009) indicate the need for the students to become more strategic with their studies, so as to act intentionally and achieve the expected results. These authors investigated students from 12 to 16 years old from secondary school in Spain. They used instruments to verify cognitive strategies (selection, organization, elaboration and memorization of information) and self-regulation strategies (planning and supervision-revision); also, they used students´ academic achievement through the grades from varied school subjects. Among the results, a higher use of different cognitive and self-regulatory study strategies brought a positive consequence and improvement in academic performance. In contrast, a lower use of these is associated with lower levels of academic performance.

Another study that associated study behavior and academic performance was developed by Rosario, Ferreira and Guimarães (2001). It was observed that the students with high performance presented a different study profile from the others. They found that they present deep motivation to learn, which is centered in the understanding of the information in a general way and supported in strategies that allow them to reach their objectives. The researchers state that one reason that makes a strategy to be operational is set in a deep approach, not a superficial one, instead. The results of this investigation reinforce the idea of understanding why the students study and how they do it either for building knowledge or school success.

The use of study strategies seems to be a promising way to make learning happen. The mastery and use of different strategies bring benefits for the learning process, which have been approached by several authors (Rosário, 2001; Rosário, Ferreira e Guimarães, 2001, Souza, 2010, Valle et al. 2009, Bartalo, 2006, Pozo, 1996). Motivational factors have been associated to the use or not of study and learning strategies, and among these, there is academic self-efficacy.

Souza (2010) affirms that self-efficacy is one of the constructs most associated to the use of study and learning strategies. The reason for this comes from the fact that students with high self-efficacy demonstrate positive expectations to their own academic results, which push them to make efforts to find more favorable strategies for the execution of the different school tasks, even in the presence of difficulties.

Regarding self-efficacy, Azzi and Polydoro (2010) discuss that when people believe that their actions can produce desirable attainments, they feel motivated to act and persist when they face potential obstacles. It is possible to bring this focus for the school context, which may require diverse study strategies, especially when the young is confronted with a new level of study, namely, high school. Nevertheless, it is important to alert that the academic self-efficacy belief by itself does not guarantee school learning. Self-efficacy has been shown to predict the necessary behavior for such learning to happen, but if the student does not have the skills and knowledge that constitute the prerequisites to learn, it will not be enough for this student to believe in his own capacities, because he will act towards this learning without success (Bandura, 1993; Schunk, 1995; Zimmerman, 1995).

The student´s self-efficacy belief is built along his school life, through the interpretation of his own school attainments and the dedicated behavior to these achievements. It is also built by interpreting the answers that are provided by his peers, teachers and other educational agents, which constitute the environmental influences.

It can be also mentioned that this belief is not static. It is different across time, because the self-efficacy belief may present oscillations, becoming stronger or weaker, demonstrating thus the dynamic feature of the belief. Azzi, Guerreiro-Casanova e Dantas (2010), warn that, because specific tendencies for each grade have been observed, there is the necessity of increasing the understanding about the academic self-efficacy under the proper characteristics of each year of high school, which can help the development of pedagogical actions.

According to Bandura (1993, 1997) the self-efficacy belief exerts influence in one´s development path. That could mean that the reflex effects of academic self-efficacy are demonstrated besides the behaviors related exclusively to learning tasks. Pro-social postures, with standards of desirable interpersonal and emotional behavior are associated with the strong intensity of academic self-efficacy belief. The opposed belief is related to harmful behavior, verbal and physical aggression (Bandura, 1993, 1997, 2006).

The occupational aspirations and the processes that guide the career decision are also influenced by the belief of academic self-efficacy (Brown & Lent, 2006). This belief has been shown to be a better predictor of career decision than the facts related to the socioeconomic aspects. In the final years of basic education, it has been demonstrated that the male students see themselves more self-efficacious than female students (Faria, Taveira & Saavedra, 2008). The experience during the three years of high school seems to alter the students´ perception concerning the capacity to plan actions to achieve professional objectives, which becomes stronger along the school years (Azzi et al., 2010).

From what was exposed, it is possible to see the important contribution of academic self-efficacy for the activities that are related to learning, and among these, the use of study and learning strategies. However, the correlation between academic self-efficacy and the use of study and learning strategies is still incipient in the Brazilian context, especially for the high school years. The objective of this research was to analyse the correlations between Academic Self-Efficacy and the use of Study and Learning Strategies from public high schools located in an important State in Brazil. As specific objectives, analyses were made of the correlations between Academic Self-Efficacy and Study and Learning Strategies considering the particular features of each year of high school and the students' condition about whether they also have a paid job or not. It is important to clarify that this study delimitates academic self-efficacy as the domain referring to the student´s perception in relation to the perceived confidence in the capacity of organizing and executing required courses of action to produce certain attainments regarding the educational formation. It is considered, therefore, the students´ perceptions about their own capabilities related to learning tasks, perform school life and career choice.

METHOD

Participants

This study was developed in nine public schools in the State of São Paulo, Brazil. In order to obtain diversity in the sample, schools in several different regions of the State were invited, in a way that big cities and small towns could be represented, in the interior of the State. The participation of the schools was assured after the authorization issued by the principal, through an Authorization Letter.

For this research, 534 high school students participated, being 64.6% (n = 345) female. From the whole sample, 183 students were taking the first year of high school, 192 the second year, and 153 the third and last year. About the age, the sample had students between 14 and 24 years old. In the first year, 25.1% (n= 14) of the students were 14 years old, 60.1% (n = 110) were 15, and 14.8% (n = 27) were between 16 and 19 years old. In the second year, 27.6% (n= 53) of the students were 15 years old, 52.1% (n= 100) were 16 and 20.3 % (n = 39) were between 17 and 19 years old. In the third year, 28.1% (n = 43) were 16 years old, 51.6% (n = 51) were 17 years old, and 17% (n = 26) were between 18 and 19 years old, and 3.3% (n= 5) were between 20 and 24 years old. All participants who were under the age of eighteen were authorized by their parents and/or responsible to participate in the study through the signature of a Free Informed Term of Consent. For the participants who were over 18 years old, it was asked them to grant permission by signing the Free Informed Term of Consent.

From this sample, 51% (n= 272) went to school in the mornings, 41.1% (n = 219) in the evenings, and 7.9% (n = 42) in the afternoon. Basically, all the students who participated in this study intend to finish high school (99.6 %, n = 529) and enter in higher education (93.4%, n = 499).

As to the condition of having a paid work, 30.8% (n = 163) of the students plead to be workers. From these, 42.2% (n= 70) said to work full time, 39.2% (n = 65) said to work part time and 18.7% (n = 31) said they did not have a fixed working schedule.

Materials

For this research three instruments for collecting data were used, which are the following:

(1) Characterization questionnaire: this instrument was elaborated by the researchers, with the objective of obtaining information about the personal characteristics of the students who participated in the research, such as, age, sex, year, period and working condition.

(2) High School Academic Self-Efficacy Scale: this scale was developed from the Higher Education Academic Scale (Polydoro & Guerreiro-Casanova, 2010), and was submitted to necessary adaptations of language and context for the understanding of high school students. After this initial adaptation, it was realized the process of spoken reflection with 10 high school students, in which their opinion was asked about the comprehension of the items that integrated the scale and about the applicability of these items to high school educational context. This procedure promoted small adjustments in the writing of the items of the scale. After the evaluation of the psychometric properties, the scale was set with 16 items. The Scale presented internal consistence of 0.886. The items were organized in three dimensions, as observed in Figure 1.

Dimension	Meant to understand	Number of items	Example of item
Self-Efficacy to learn	Perceived confidence in the capacity of making efforts to get involved in school activities, considering the cognitive, motivational and behavioral aspects related to the process of learning and academic performance.	8 items	How much can I motivate myself to do the activities/tasks related to this school subject?
Self-Efficacy to perform school life	Perceived confidence in the capability of performing school life, considering the collaborative engagement with peers and the school/institution	4 items	How much can I contribute with ideas to improve my school?
Self-Efficacy for choosing career	Perceived confidence in the capability to search information and plan relevant actions for deciding a career.	4 items	How much can I define with security what I intend to follow as my profession among the several existing diverse possibilities?

Figure 1 – description of the dimensions of the High School Academic Self-Efficacy instrument.

In order to answer them, the students were guided to think about the current school situation. Then, the respondents had to indicate how much they could perform the proposed situation in each of the items, ranging from 1 for the least capable to 7 for the most capable.

(3) Learning and Study Learning Strategies Inventory. This instrument was originally elaborated by Weinstein e Palmer (1990) and after, it was translated into Portuguese from Portugal by Figueira (1994). In Brazil, it was translated and validated by Bartalo (2006). For the present research only the dimension Information Processing was used, which can be observed in Figure 2. It is composed by 12 out of 88 items of the mentioned instrument. This dimension presents internal consistency of $\alpha = 0.82$.

Dimension	Meant to understand	Exemple of item
Information Processing	Identify the use of verbal and symbolic strategies, the monitoring of comprehension and thinking, as well as the establishment of bridges between what they know and what they are trying to learn and remember.	I try to identify the main ideas when the teacher of this school subject is teaching.

Figure 2. Description of the Information Processing dimension from the Learn and Study Strategies Inventory.

Before starting to answer to the dimension of the Learn and Study Strategies, the student was explained to think about his usual behavior related to the strategies mentioned in the instrument. In order to respond, the student could choose from 1 to 5, meaning that 1 represented the behavior never performed by the student, and 5 the behavior always performed by the student during his study and learning activities.

Procedures
The research project was submitted to the Research Ethics Committee of Campinas State University and after its approval (letter nº1185/2009) the data was collected. The researches contacted the Boards of Education and the responsible in command of the schools with the purpose of presenting information about the objectives of the research and ask authorization to collect data. The schedule was organized according to the availability of the Portuguese teachers, because the students had to answer the instruments during the classes of this school subject.
The researchers went to the respective schools in the scheduled days. They introduced themselves and invited the students to answer the instruments. Initially, the students were invited to voluntarily participate.

They were explained about the content of the research, that data would be kept confidential and with either no harm for the ones who participated, or benefits for those who decided to respond. Those students who accepted in taking part in the research were explained to take the Free Informed Term of Consent to their parents or so to be signed and brought back to the researchers the following day, so that they could answer the instruments. The collection of data was collectively made, inside the classroom, during the class of Portuguese. The students were oriented to answer the questions of the instruments according to with their perceptions about that school subject. The participants answered the three instruments following the same order, starting with the Characterization Questionnaire, then High School Academic Self-Efficacy Scale, and finally Study and Learning Strategies Inventory. The instruments are self-explainable, however, the researcher stayed inside the classroom in order to clarify possible doubts. There was no time limit to answer, therefore, the average time was 20 minutes. The collection of data happened in only one meeting with the different groups because of the school year and period. It happened between the months of April and August 2010.

Data analysis procedure
The protocols answered by the students were visually checked by the researchers to see if all the answers were completed. The ones that were had less than 90% answered were discharged. The answers were inserted in the statistic program SPSS (version 18.0) and 20% of the sample was randomly checked. It was verified that the data was non-parametric by the Kolmogorov-Sminov test, and the Spearman correlation test was applied among the variables according to the objectives, besides the descriptive data of the characterization.

RESULTS
The results are presented below starting from the correlations between Academic Self-Efficacy (SE) (total result, self-efficacy to learn, self-efficacy to perform school life and self-efficacy for career decision), and Study and Learning Strategies (SLS), followed by the correlations according to with the school year, the period of study and the students´ conditions about working. It is interesting to clarify that the strength of the correlation discussed here was classified as: weak ($\rho \leq 0.399$), moderate ($\rho \leq 0.400 \geq 0.699$) and strong ($\rho \geq 0.700$) (Dancey & Reidy, 2006), and all correlations found were positive and significant. It is worth mentioning that the answers given by the students were based on the Portuguese school subject.

Table 1 - Correlation between Study and Learning Strategies (SLS) and Academic Self-Efficacy (SE) – general result, by school year, by period and by working condition. ($**p < 0.0001$)

		Academic Self-Efficacy	Self-Efficacy to learn	Self-Efficacy to perform school life	Self-Efficacy for career decision
Study and Learning Strategies		0.638**	0.648**	0.394**	0.494**
	1st year	0.648**	0.607**	0.449**	0.493**
	2nd year	0.678**	0.682**	0.386**	0.574**
	3rd year	0.602**	0.651**	0.375**	0.417**
	Morning	0.624**	0.558**	0.350**	0.470**
	Afternoon	0.718**	0.841**	0.509**	0.624**
	Evening	0.629**	0.660**	0.427**	0.503**
	Works	0.676**	0.712**	0.447**	0.571**
	Does not work	0.619**	0.618**	0.363**	0.461**

It was observed that the correlation found between Academic SE and SLS was weak only for the dimension "perform school life". About the correlation between total Academic SE and SLS, it was moderate for the

dimensions "learn" and "career dimension", having "learn" a higher score between these two. These correlations were significant.

As can be observed in Table 1, the correlation between Academic SE with SLS was moderate, positive, and significant for all school years. The dimension SE to learn also presented moderate, positive and significant correlations with SLS for all school years. The dimension SE to perform school life presented moderate correlation with SLS for the first year students, and demonstrated weak correlation for second and third year students. The dimension SE for career decision presented moderate correlation with SLS for all school years. The correlations between Academic SE and SLS was positive and significant for all periods, as seen in Table 1. In this same Table, it is possible to verify that the correlation between SE and SLS was moderate for the afternoon and evening periods, being the latter one strong. The dimension SE to learn, presented moderate correlation with morning and evening periods, with strong correlation with the afternoon period. The dimension SE to perform school life presented weak correlation with the morning period, but moderate with afternoon and evening periods. The dimension SE for career decision had moderate correlation with the three school periods.

The correlations between Academic SE and SLS was positive and significant for students who work and for the students who do not. The lowest correlation was between SE to perform school life and SLS, either for the students who work (moderate correlation) or for those who do not (weak correlation). The only strong correlation found was between SE to learn and SLS for the students who work. Generally, the students who work presented higher correlations between total SE and SLS and its dimensions.

DISCUSSION

Overall, the results found in the analysis between Academic SE and SLS Strategies indicated positive and significant correlations with moderate magnitude in Academic SE, SE to learn and SE for career decision (ρ= 0.638, 0.648 e 0.494, respectively), which suggests that those students who judge themselves academically more capable, also use study and learning strategies for the Portuguese subject more intensively. These findings reinforce the data found by Neves and Faria (2007). The authors investigated Academic Self-efficacy of Portuguese and Math in 207 students from the 9th and 10th school year in a city in Porto. They used instruments to analyze self-efficacy, the causal attributions and academic performance in these two school subjects. The results found revealed significant and positive correlations between self-efficacy and school achievement. Thus, it seems that academic self-efficacy exerts a relevant role in the motivation and school accomplishment. This role is in a way that psychopedagogical interventions can be planned towards creating conditions to promote motivation and school achievement driven to specific and related domains. These conditions must be realistic, and promote the use of learning strategies which are adequate to the task.

When considering specifically the correlation between SE for performing school life with SLS, weak intensity was observed (0.394**). This low intensity may be a result of the inexistence of items to measure the study and learning strategies that consider learning strategies performed cooperatively with one or more peers. The dimension SE for Performing School Life is meant to verify the students´ perceptions about, for instance, the capability to work in groups or ask for help for a colleague, in a way to consider the necessary attitudes to learning, considering the social and interpersonal aspects that surround the learning, as suggested by Bandura (1993:1997).

Regarding the correlations verified between SE and SLS according to the school years, it was found positive and significant correlations for all of them. Only the dimension SE to perform school life presented differences of intensity for the years, being moderate in the 1st year, and weak for the 2nd and 3rd years. This result indicates the importance of investigating the aspects which are involved in the lowering of the intensity of this correlation. This dimension analyses the perception of the capacity about the aspects involved in performing school life (working in groups or search information about the infrastructure and facilities of the school the student goes to) therefore, related to social life. The instrument that was used in this research to identify the use of SLS has only items related to learning strategies that are developed individually, and this might have contributed to lower the observed intensity.

When the correlations between the periods were analysed, it was observed that the evening students (strong correlation) demonstrated a more intense correlation between Academic SE and SLS than the morning students (moderate) and the afternoon ones (moderate) in all dimensions. In this regard, it is important to consider that the self-efficacy perception is built by contextual issues, so that, eventually, the environmental conditions that are different in each period (for example, different school agents, less researched students in the evening) might have contributed to raise the intensity of the observed correlation. It would be interesting to analyze whether those differences in intensity of the correlation may be associated to the students´ working condition. From the information gathered, 42.2% (n= 70) of the students work full time, which

allowed to infer that they went to school in the evening. Also, 39.2% (n = 65) of the respondents said to work part time but there was no possibility to understand whether they went to school in the mornings or afternoons.

The correlations found between the variables researched considering the condition of working or non-working students were all positive and significant as well. When compared, a difference is observed, because there are more intense correlations when considering the working students. It is important the strong correlation observed between Academic SE and SLS for the condition of the working students, what seems to indicate that they use more those strategies as more self-efficacious they become. The correlations observed between SE for career decision and SLS were moderate for both the working and non-working students. The experience with a working activity may represent clearer objectives for one´s personal aims. It may also contribute to greater efforts towards the achievement of goals, for example, the exercise of studying. Rosário and colleagues (2006) propose that helping the students to design possibilities and realistic professional proposals is an important educative feature, associated with thinking about a challenging future, in order to make the student manage his school life and build his own school path. The authors state the need of going beyond helping them solve problems, but to give them a sense of being able to change the course of unsuccesses, with a more preventive rather than remedial attitude.

CONSIDERATIONS

The perception of Academic SE and the use of SLS seem to be relevant constructs in the context of the Portuguese classes, as investigated here. It is important to be aware about the clarity and objectiveness of the definition of these constructs, and the specificity of the domain to be investigated. This is proposed by the study of Torres and Neves (2010) that investigated these constructs associated to school performance with elementary students in the city of Braga. The results indicated that there may be influence of use of learning strategies when forming efficacy expectations, being significant when it is considered self-efficacy in Portuguese and not in Math because they can differ as to the use of strategies. They also mention that the expectations of academic efficacy towards the specific attainment domains that were studied (Portuguese and Math domains) influenced in a positive and significant way the score to Portuguese and to Math.

In the correlation between Academic SE and SLS under the focus of the school years, it is pointed out the decrease of the intensity of the correlation about SE to perform school life from the 1st year to the 2nd and 3rd ones. Besides the considerations already made about the instrument, it is worth investigating about the practices of incentives for the execution of collaborative and participative activities, considering peers and the school context, corroborating Azzi and colleagues (2010).

When considering the focus of the school period, the correlation found between Academic SE and SLS seems to indicate that the time the students go to school has to do with the motivation to learn. It is stressed the need of considering the environmental and contextual differences for each period, for the realization of the pedagogical activities developed in the classroom and/or at school.

The students´ condition about working or not seem to be an important variable about the aspects of perceived SE and the use of SLS, once the observed correlations for these were more intense. As mentioned before, researches have highlighted the contribution of academic SE for career decision (Brown & Lent, 2006; Faria, Taveira & Saavedra, 2008), over other aspects, as the socioeconomic one.

As to limitations, it can be mentioned that the sample does not represent the whole diversity of Brazilian public schools. The range of this sample was limited by the difficulty to obtain authorization from parents or responsible for the students who are under 18 years old.

As to contributions, the correlations of this study indicate that also in the Brazilian population, the belief of Academic SE is associated to the prediction of actions toward the use of SLS. From the obtained results, important educational implications must be discussed for the Brazilian reality.

327 - Support to Educational Leadership From School Counselors. The Spanish Case

Jesús Domingo[1] and Katia Caballero[2]
Faculty of Education Sciences, University of Granada, Spain
[1]jdomingo@ugr.es, [2]kballero@ugr.es

Astract: This paper presents the results obtained through a research project I+D, funded by Ministry of Education. It has been used a multi-case-study methodology that combine interviews data to principals, teachers and counselors of different schools. The aim is to understand cultural and professional identity keys that facilitate o difficult the development of a coordinated action principal-counselor to practice and distribute the leadership of learning to the community. It gives a revision of the current literature about the subject. It is offered an overview of the interaction between educational counseling and leadership for learning. We describe and discuss the duties and possibilities of the support services and school counselors. We analyze the organizational structures that will be able to enhance the educational principles in a culture of change and improvement of results. And finally, we contribute with some conclusions and implications to appeal for an academic and professional debate.

Keywords: leadership for learning, distributed leadership, school counselor, school improvement, relationship counselor and principal.

RESEARCH PROBLEM

There are empirical proofs about the effectiveness of leadership for learning and its impact on outcomes (Leithwood, 2009). Principals can influence on results and give to the school a strong pedagogical leadership in order to improve the school and the relationships between teachers, students and curriculum (Elmore, 2010).

As emphasized in the report "Improving School Leadership" (OECD, 2009), the issue is now a priority for the system (Pont, Nusch, & Moorman, 2008) that must be addressed. But it is not returning to the romantic lead, but to explore new options. A distributed educational leadership within the community (Harris, 2004), supported by supervisory and advisory functions, can be an important element for cultural change at the school. In this sense, it is interesting to explore how to make possible and efficient the support for educational leadership in order to be shared by work's teams within a community educational project.

TALIS results (OECD, 2009) show the controversies for this leadership in Spain. It is evidence that in Spanish case does not exist educational and management leadership. The principals in this country have had few powers to get an educational leadership.

Perhaps there are enough global diagnoses and specific stories to know the reasons of this situation (Coronel & Fernández, 2002; Gago, 2006; Viñao, 2005). So, it is necessary to redefine duties in order to recompose the principal's leadership. The improvement of secondary education institutions is a priority, even if it is complex and needs the concurrence of internal and situational factors. Educational administration should be involved for subsequently to promote, develop and support the leadership for learning. This requires a professional debate about what leadership is, and what we need to make viable and maintain it over time.

Promote a professional performance, in line with what the current pedagogical knowledge as the most relevant points to promote the improvement of schools and learning outcomes is a task is highly complex. And it must be done in a realistic and possibility. The romantic speeches blaming or victim and little can bring.

In this context there are significant changes, supporting the transition from a bureaucratic model to a pedagogical orientation, designed to improve learning and schools' outcomes (MEC, 2007; DOGC, 2010). But still there are overregulations and limitations that cannot be ignored (Bolívar, 2004, 2006). Next to it there is a current of "best practices" in this sense. There are inquiries about how learning leadership is produced and in which circumstances by scholar principals (Bolívar, Domingo & Caballero, 2011).

The evolution of the principal's role in the Spanish case is accompanied of some singularities: There is not only a principal, but a management team, and responsibility for education improvement has to be distributed among teaching teams. In our context there are participation and coordination structures among teachers, support structures and other communities that can offer a new horizon. Many of them have an interesting repertoire of "good practices" to support the improvement, serving as example to go on its way.

Out f those, we are interested in the figure of the school counselor and more particularly on that of the guiding counselor of Secondary Education. The reasons are obvious. On the one hand, they have a real presence in all secondary schools, stage that changes on all reforms. And, secondly, their psychological training and the role of the norm that defines their functions and field of work, gives them special educational vision and a strategic position.

Along with this, it is important to bear in mind that the school management in Spain is not professionalized and that is performed by a teacher chosen by their colleagues who have a certain profile. For this reason, in certain circumstances, some support, advice and strategic and programmatic tools might be welcome. This supports may be perceived as irrelevant interferences. Life histories, professional and institutional culture and another set of circumstances are intertwined and weave complex scenarios for or against the professional meeting. For this reason it is appropriate to enter into the professional life experiences of counselors and managers.

THE WAY OF COUNSELORS IN SPAIN: THE EXPERT INTERVENTION TOWARDS ADVICE FOR IMPROVING AS AN AGENT OF CHANGE

If the idea that support services were necessary but not claimed is already antique, so it is the fact that the times in which one had to earn a place are already. Today virtually no one disputes that the support and advice are a key factor in the improvement process. Educational guidance in secondary schools has pass from being seen as something new start to get valued. Many teachers recognize the importance of the advisory role of the school counselor. Counselors start to get involved in the school and play a necessary role, especially in the Action Tutorial and in its usual "quarters" of professional and personal counseling, and in areas related to the special educational needs. But they are still left aside. Hence the complaint voiced by De la Oliva, Martín & Vélaz de Medrano,

> "The psycho pedagogic intervention is contributing to the improvement of education, but still due to the marginal performances schools, the jump to the core of the task in the classroom and in the center is to be given" (2005, p. 67).

It is true that initially their role in improving schools has been seriously eroded, both by the expert guidance in problematic and marginal areas that has governed them and also by the difficulty to fit in the organizational and pedagogical structure of the centers. They don't seem to be placed on the hard dimensions of life and educative change. Voluntarily or not, the role of the counselor has been confined to the periphery of the educational activity. Internships are often inadequately developed within the ambit of the center, have inherited inertia that seem difficult to change and address specific issues that do not concern what should happen in classrooms on a daily basis (Solé, 1998, Del Rincon, 2001). They have not done significant impact on the institutional and professional culture, in order to make out of tutoring something inherent in the teaching. Apart from that, promotion of good teaching for all does not create professional and institutional consensus and commitment.

The guidance counselors construct their social role in each context, depending on what "all" think they should do about the needs they perceive, and their conception of the tasks of the counselor. Although the norm, is clear on that sense and enables them to go further and make a change. Boza, Toscana & Salas (2007, p. 125), doing a revision about the counselors' duties, they observe that "the advisory role to the different members of the educational community seems one of the most defined and repeated".

One of the controversies is how to manage the difficult balance between give an expert answer to the daily problems and breaking with these dynamics looking for new professional spaces more committed with the improvement of the education and the centre, generating new frictions with colleagues who do not completely accept this new role or interference.

> "In our opinion, counselors, although they are concerned about the issues related to the organization and coordination of the educational guidance in their centers, continue to struggle between the direct intervention on the typical recipients of guidance, either through individual assessment and advice, or through programs and the indirect intervention characteristic of the advice, as a consult or as collaborative and systemic advice" (Boza, Toscana & Salas, 2007, 127).

With the arrival of programs intervention models, specifically to influence on specific issues, but with an overall view and integrating efforts, a new perspective has been opened as well as a new, more diverse horizon. However, the results are still uncertain. There are some isolated successes: one works with a

systemic vision supporting the management team activities and creating self-review dynamics around those new improvement fields (Domingo, 2010). However, most of them are just names (programs, counseling, self- review...) for the same marginal actions.

In Spain school counselor figure is well established with broad functions that go beyond the purely technical or clinical intervention. As highlighted in other contexts (Stone & Clark, 2001, Clark & Amatea, 2004), school counselors perception as educational leaders, students counselors, and agents of social change is changing, with higher degree of intervention and collaboration with those people who are important in the lives of students and with a systemic vision and mission (ASCA, 2008). One starts talking about the counselors as "change agents" (Santana, 2008) and goes one step further empowering the professional figure when describing it as "a leader committed to continuous improvement of the school" (Martínez, Krichesky, & García, 2010, p.107; DeVoss & Andrews, 2006).

In this context, having lost the innocence about change, but having certain theoretical and practical support as well as new approaches (Monereo & Pozo, 2005; Domingo, 2009), we are positioned on the assumption that you can resize the current role of school counselors to contribute more strongly, to internally prepare schools in improving education for all students (Domingo, 2006). It is not about creating more structures and services, or overloading the already existing, but to redirect and enhance the existing ones to more productive ones in school improvement, empowering counselors (McMahon, Mason & Paisey, 2009).

THE SCHOOL COUNSELOR AS AN AGENT OF CHANGE. WORKING CLOSELY WITH THE MANAGEMENT TEAM FOR THE IMPROVEMENT OF LEARNING

The ultimate purpose of the "new" internal support services is to mediate, and give technical support to the mobilization of the internal capacities for change (Hopkins, 2007). Especially those aimed at developing the core teaching (Elmore, 2010) with "good" teaching-learning processes that give rise to commitments and reflective processes in which they learn together without a complex change (Hargreaves, Earl, Moore & Manning, 2001). It would be a professional support to strengthen and operationalize the learning needs of the community starting from supportive and collaborative statements (Bolan et al., 2005) and distribution of leadership (Harris, 2004; Spillane, 2006, Leithwood, 2009).

We agree with Martinez, Krichesky & García (2010) conception of the figure of the school counselor as

> "an educational agent implicated in the school improvement, working with teachers to improve students' development in a comprehensive manner, working closely with the management team and promoting the improvement in daily practice" (p.110).

For this reason, the practices of these professional advisers should arbitrate and revitalize processes that allow the critical analysis of basic grammars at all three levels of action (Domingo, 2010b): 1) institutional dimension to set directions, 2) strategic dimension to bring together the teacher's actions around areas of improvement, from redesigning the organization, and 3) Instruction management and interaction in the classroom or in formal and informal contexts. Bolivar & Romero (2009) indicate that the goodness of support services is to determine on how they are able to:

> Articulating the community individual and collective teaching action in a joint project along the lines of the basics that promote the education system.
> Helping to set the school as a project.
> Influencing on the core of the improvement, this is, the teaching and learning processes.

Ultimately, it comes to promoting a climate of collaboration and learning community, supporting work dynamics, potentially formative about dimensions, dynamics and relevant content for the development of an intercultural project group. These actions become a unique opportunity for self-revision, reconstruction and integration of the center. It is a unique opportunity to get and give advice on overall planning, development, evaluation and innovation of the curriculum processes and at the same time, mediating on the appropriation and use of proposals from teachers.

Along with this global perspective, the community and center approach, the reality is that, without losing sight of this goal, increases the functionality to find this integration of voices, concerns, efforts and perspectives on more tangible things. Thus, it is about specific programs, or particular task projects or globalizing tasks linked to the classroom, where this process of (re) construction becomes a more real perspective to work on a shared vision.

All in all, this professional is now located in a strategic position which, while working very close to the classroom (Domingo, 2001), has a broad overview and systemic vision (House & Hayes, 2002), allowing the collaboration between faculty and management team (Stone & Dahir, 2006; Janson, Stone & Clark, 2009).

Thus, Martínez, Krichesky, & García (2010), indicate that work counselors do with management teams must be in line with the supporting the role of educational leadership and also finding support to develop their programs that permeate the life of the school. For this aim, they cannot enter into dispute and must make a solid and interrelated team, with an open, sincere and permanent communication, and combine their strengths and skills towards the improvement of a global learning.

With all this, we can say that is well documented that these support services, without being the key element of change, have a supporting role on the exercise of leadership for learning, and vice versa (Lambie, & Williamson, 2004; Wolker, 2006). The American School Counselor Association (ASCA, 2008), when defining new professional skills for counselors, argues that these can greatly contribute in this regard, although this reality is far from be considered achieved (Amatea & Clark, 2005). And in that sense, for better or for worse, there are involved a lot of different sets of perceptions that occur between counselors and managers (Kirchner, & Setchfield, 2001).

METHODOLOGICAL FRAMEWORK: DESIGN AND RESEARCH DEVELOPMENT

If principals and counselor experiences in educational leadership are important, we must deep on them. We are not interested in the landscape, such as understanding the most important dimensions and circumstances which may render both support elements such as distorting professional relationship. We approach through a qualitative study as part of a wider research, tackled in other place (Bolivar, Domingo, & Knight, 2011).

Counseling and pedagogical advice are carried out in complex ways. They are dynamic, flexible and a panoramic issue which can be understood through biographical and narrative approaches Bolívar, Domingo & Fernandez, 2001), especially appropriated to the current time of disappointment postmodern of narratives and vindication of the relevance of the personal subject (Bolívar, 2002).

It is not ignore or belittle the contributions of basic research into counseling, but to claim that you can also learn from concrete facts, from what it is said of them, from constructed discursive reality or anything that is not said or hidden within a logical story (Domingo, 2005).

It would be good to approach this issue through ways closer and more human. We promote the interpretation in first person as relevant and definitive in the human action (Ricoeur, 1996). Having their own experiences and interprets such events is a source of training that projects the future from the accumulated knowledge and experience. The biographical narrative research provides a conceptual and methodological framework to analyze key aspects of the education development (Connelly & Clandinin, 2000). The personal stories of the experience provided the biographical framework that makes intelligible the professional development of teachers, becoming a new form of knowledge.

Only hearing and understanding "the lives and experiences", with respect, it is possible to establish meaningful bridges between "their knowledge" and the others, between their truth and what is objective... With that we can walk towards the construction and appropriation of a significant change (Fullan, 2007).

A professional life story can give relevant information about research interests, clues about the kind of discourse and reasons that justify it. Everything within a textual logic that gives sense and coherence to the memories of a global and professional distributed in episodes.

The complexity of counseling profession can be seen through the set of responsibilities and challenges. In many cases these duties are not specific to the profession and can become an inconvenient (which operate in the opposite direction of improvement), although there are promoted by educational administrations. It is a practice likely vulnerable to a collateral, uncontrolled and unwanted effect, sometimes accompanied by a pessimistic adaptation to the reality of the profession.

The hide side of counseling lets us to analyze the circumstances, interests useful for assessing the impact of professional practice in order to reconsider it (Domingo, 2005).

If we could not know the stories that describe and explain these situations within the profession, we will only have idealized, stereotypical and unrealistic views of this profession. Listening voices, we can make possible the change (beyond cultural and contextual differences) through reflection.

Therefore, we carry out a study –in process-, in which 10 secondary schools, characterized by educational administration as examples of good practices, were selected for interviews. We approached them, asking to teachers, counselors and principals the followed processes to get a high quality level. We started with a number of principals and counselors, but after, we increase the informants in order to contrast and deep on different perspectives and discordances.

We took the interview process proposed by Kelchtermans & Vandenberghe (1994), based on the realization of different interviews with individual goals to deep in different aspects of the life stories. The process had the following phases:

- First phase: to identify who they are and why they do what they do in order to understand their beliefs and professional experiences.
- Second phase: to analyze the information and return it for validation.
- Third phase: to deep into dimensions, milestones, conditions, circumstances, etc. It is about understanding and depth, while they identify supports and discrepancies of their thoughts.
- Fourth phase: A new analysis and validation is realized, this time deeper (narrative and paradigmatic, lineal and transversal), to join it with the rest of voices that talk about the same circumstances, in the same school and time, although with different roles and personal perspectives.
- Fifth phase: We conclude with a group interview, to contrast and check overall positioning.

PRESENTATION AND DISCUSSION OF FIRST RESEARCH RESULTS

From the biographical narratives of professional and institutional experience, we did a dialectic reconstruction to give sense to the different stories. We analyzed the dynamics and factors that promote change and the effects they produce. From these results, we have identified some key dimensions of qualitative improvement of secondary education. It is outstanding the strong role gave to the counselors. These professionals' activities, properly focused, can contribute to internal training to schools in order to change. To do this, although we only have some preliminary results, it seems this work should be based on:

(1) Collaborating with the head team in order to do a school project and to value the practices and activities that help to promote a good learning.

"In our case, the most important has been to take the counselor's role in the group, in order to delegate and ask for tasks, but not from the imposition, but from the responsibility and making people think: what's going on?, Is this true?; to listen critics that occur in the school ... "(DIR09).

"I cannot get into the departments, plans or almost nothing, I am not an educational authority. They respect me and they let me take decisions, but also because the principal supports me and we are on the same line of action "(SC03).

"It is vital that we work together and coordinated by a shared vision of the school. Each one must work in their area, but within a common educational project. So we add up. But if not, you could say that counselors, instead of orienting, they disorient "(DIR01).

"I could not count on principal; I could not help to departments or cycles. The result was that I was not able to create conditions and processes to pressure for change "(SC08).

"It is very important to foster and improve the visibility of connection between counselor and principal, and the participation of both in the educational project" (SC07).

(2) Supporting educational activities of the departments as a platform for innovation in education and professional development;

"The most important for getting improvement is the staff collaboration, communication and teamwork. Teachers and didactic departments must participate and get involved. And the principal and counselor must support them "(DIR10)

"The most important thing that counselor can do is to facilitate the teamwork and define the north and orientation in order to not get lost" (DIR04).

"In this raging storm, we cannot doubt of ourselves as teachers. We must have a point of credibility and professional dignity and work together in which is basic, doing what we have to do" (PRO08).

"The response to the challenge of innovation requires connecting the psycho pedagogical knowledge that counselors have with the knowledge of the rest of teachers" (DIR5).

"Get in their teaching teams does not mean to take them to our field. We do not want to take their space. It is better to think with them on what works and what students get when they do what they do, and from there, all of us must take appropriate decisions together" (SO09).

(3) (Re) constructing their professional performance in order to move from superficial to basic problems, from specific to systemic actions.

"Now you ask me, looking at my life, I would change the priority of our duties and activities. We did a lot of tasks, which were marked as priority and necessary, when in fact the necessaries were other very different" (SC12).

"If we cannot jump out of our particular problem to the common problems of improvement that needs to be worked together, it is very difficult to overcome and transfer to everyday life. We have to make this jump a philosophy to work on a new framework of what should be an educational project "(SC04).

"We never start from nothing; there is a previous history that influences. Wanting or not I have to live with the memory of previous counselor. Peers perceive me as a continuation of their work. Anything you do outside of that continuity is too difficult" (SC03).

(4) Sharing tasks, responsibilities, chats and good stories of learning, perspectives and arguments.

"Listening to us, talking and seeing what is behind it ... helping us to structure and analyze the problems we have and give a solution. That helps us a lot. I do not know if it is self-evaluation or self-reflection, but it is useful and, ultimately, it gives us tools to face new caseloads" (PRO13).

"I remember a counselor who knew a lot, but we did not understand him. It was as if an unknown object, which spoke of unrecognizable terms and so far from practice, in the end we did not listen to him"(PRO7).

"If we do not know the daily rules, stories of everyday life, interests and patterns of living in the community, in a tolerant way, it is impossible to share common spaces with diverse people" (DIR06).

(5) Acting with a dialectical approach, collaborative processes that help the community to engage with the improvement;

"From the perspective of teachers, the role model that they prefer is quite close to a procedural guidance and collaborative, although this trend tend to be lesser in comparison with demands of specialized counseling for particular issues and problems" (SC02).

"After living experiences of joint elaboration of Action Plan Tutorial, from the reality, concerns and colleagues' problems, I understood the value of the process and the trust on the team, giving it time but always so careful without losing interest or perspective" (SC05).

"It seems we agree on thinking that the best way of work is to pay attention to the processes and to reflect in action, promoting teamwork and coordinated actions" (DIR06).

"The strategies to use are not the most important, but the effects they produce for the school improvement and development and the increase of autonomy and teachers' professionalism" (SC01).

These snippets of voice only make a preliminary approach. There are not decisive evidences that can be extrapolated. But they are alerts, notices and invitations to go on researching and to participate in the debate. These voices coincide with international studies and current literature. With appropriate changes in counselors' duties, focused on advising and a team' work between principal and teachers, it is possible to get a leadership for learning, the school's improvement and its development as a community of learning. The process to get it should be a shared way based on collaborative reflection and commitment.

339 - Challenges to Promoting Quality in Pre-Service Practicum Experiences

Tom Russell[1] and Andrea K. Martin2

Faculty of Education, Queen's University, Kingston, Ontario, Canada
[1]tom.russell@queensu.ca, [2]andrea.martin@queensu.ca

Abstract: This paper arises from our concernsthat, while the practicum continues to be perceived as the single most important and valuable element of our preservice program, the practicum still falls far short of its full and necessary potential in preparing new teachers for their full-time teaching responsibilities. We draw on relevant literature, personal experiences in schools, and perceptions of associate (mentor) teachers expressed in a focus-group discussion. Qualitative data from the perspectives of associate teachers, teacher candidates and a faculty supervisor lead us to suggest that promoting quality in practicum experiences is far more complex than meets the untrained eye. Promoting such quality requires teaching candidates how to learn from their practicum experiences in ways that make explicit the perspective of school as a culture and the inherent complexity of creating classroom contexts of productive learning. Promoting quality also requires that teacher educators improve the quality of their own teaching.

Keywords: apprenticeship of observation, learning from experience, culture, assumptions

INTRODUCTION

This paper arises from our concerns, developed over 10 years of practicum supervision experiences, that while the practicum continues to be perceived as the single most important and valuable element of our preservice program, the practicum still falls far short of its full and necessary potential in preparing new teachers for their full-time teaching responsibilities. We draw on relevant literature, on personal experiences in schools, and on perceptions of associate (cooperating or mentor) teachers expressed in a focus-group discussion. Qualitative data from the perspectives of associate teachers, teacher candidates and a faculty supervisor lead us to suggest that promoting quality in practicum experiences is far more complex than meets the untrained eye. The reality that preservice programs can never fully prepare a new teacher for school realities has been acknowledged by the creation of induction programs for new teachers. Connecting messages from education classrooms to in-school contexts is one rationale for promoting the quality of learning from practicum experiences. Promoting such quality requires teaching candidates how to learn from their practicum experiences in ways that make explicit the perspective of school as a culture and the inherent complexity of creating classroom contexts of productive learning. Promoting quality also requires that teacher educators improve the quality of their own teaching. The ultimate folly of teacher education institutions involves trying to improve schools by filling new teachers with dreams of new research-based practices without first attending to and improving the teacher educators' own teaching. Darling-Hammond (2006, pp. 279-280) cites the only-too-plausible criticism that "one reason professors spend so much time trying to change K-12 schools is that they know they cannot change their own organizations."

We all approach the practicum experience with traditional assumptions of which we are typically unaware. In our own program, major re-structuring generated many new expectations as well as new challenges. As expectations failed to materialize and as challenges proved to be more complex than anticipated, we personally were forced to re-examine our own practices and to move beyond the default perspectives of teaching as telling and learning as listening. We have no simple recipes, but we have far greater understanding of the reasons why promoting quality in practicum experiences continues to be an elusive yet worthwhile goal. A conceptual change approach that supports many new pedagogical strategies is often recommended to new teachers. This raises major challenges for the basic structural premise of most teacher education programs that new strategies are first learned in university classes and then practiced in school placements (Korthagen, 2010). Until teacher education programs begin to come to terms with the fundamental authority of experience for all types of learning, their structures are likely to contradict their research-based premises and rhetoric, leaving candidates discounting the significance of their formal courses in education. Our efforts to inquire into our own teaching and to listen to teacher candidates and associate teachers on the topic of improving the quality of practicum learning experiences have generated a robust agenda for further exploration and the paper concludes with that agenda.

The ultimate folly of teacher education institutions involves trying to improve schools by filling new teachers with dreams of new research-based practices without first attending to and improving the teacher educators' own teaching. Darling-Hammond (2006, pp. 279-280) cites the only-too-plausible criticism that "one reason professors spend so much time trying to change K-12 schools is that they know they cannot change their own organizations." The reality that preservice programs can never fully prepare a new teacher for school realities has been recognized by the creation of induction programs. Connecting messages from education classrooms to in-school contexts is one rationale for promoting the quality of learning from practicum experiences. Promoting such quality requires teaching candidates how to learn from their practicum experiences in ways that make explicit the perspective of school as a culture (Sarason, 1996) and the inherent complexity of creating classroom contexts of productive learning (Sarason, 1998).

Objective and context

This paper arises from our concerns developed over 10 years of practicum supervision that, while the practicum continues to be perceived as the single most important and valuable element of our preservice program, the practicum still falls far short of its full and necessary potential in preparing new teachers for their full-time teaching responsibilities. In constructing our argument, we draw on relevant literature, on personal experiences in schools, and on perceptions of associate (cooperating) teachers expressed in a focus-group discussion.

We offer recommendations for promoting quality in pre-service practicum experiences by interpreting teacher candidates' and associate teachers' perspectives. Darling-Hammond (2006, p. 279) cites the longstanding concern that "candidates do not learn deeply about how to understand and handle real problems of practice." Nuthall reviewed his own extensive career in educational research and drew these insights:

> It is important to search out independent evidence that the widely accepted routines of teaching are in fact serving the purposes for which they are enacted. We need to find a critical vantage point from outside the routines and their supporting myths. . . . The approach I have learned to take is to look at teaching through the eyes of students and to gather detailed data about the experiences of individual students. (Nuthall, 2005, p.925)

Through conversations with teacher candidates and associate teachers, we are trying to create critical vantage points for ourselves and others to challenge familiar myths associated with practicum learning. We take Nuthall to be seeking a critical vantage point that recognizes that the cultural features of schooling tend to be invisibly embedded in the daily routines of the teacher-student relationship. Routines are both necessary and inevitable, but any efforts to create more productive contexts for learning will necessarily fail if the cultural features of schooling are not identified explicitly and addressed directly. This paper documents our initial efforts to help teacher candidates interpret their professional learning experiences in terms of the cultural features of practicum settings and our attempts to understand more fully the complex challenges of learning from practicum experiences.

Theoretical perspectives and mode of inquiry

We begin with literature on conceptual change and development (see also Duschl & Hamilton, 1998) that is linked to literature on reflective practice, because changes in thinking and changes in practice go hand-in-hand with the development of new understandings. Kagan (1992) summarizes the recommendations of Posner et al. (1982) for how teachers can promote students' conceptual change. Teachers must (a) help students make their implicit beliefs explicit, (b) confront students with the inadequacies of their beliefs, and (c) provide extended opportunities for integrating and differentiating old and new knowledge, eliminating brittle preconceptions that impede learning and elaborating anchors that facilitate learning.

Hodson (1998) makes the case that, in science teaching, creating conditions for cognitive conflict where teachers challenge students to look for limitations in their views or deliberately provide examples of discrepant or surprising events, often through hands-on demonstrations or activities, can spur reconceptualization. However, we question the extent to which preservice teacher education anchors the practicum within a conceptual change framework, explores conceptual change theory, probes the concepts that teacher candidates hold about teaching and learning, provokes cognitive conflict, and supports candidates with approaches and strategies to encourage and sustain conceptual change. Unless prospective teachers are *directly* challenged to confront their own alternative conceptions and work through the process of conceptual change, it is highly unlikely that they will be able to support their own students in doing so. Unless learning from practicum experiences is *explicitly* supported and interpreted, those learning to teach are not likely to move beyond what they have already learned from a long "apprenticeship of observation" (Lortie, 1975). Lortie named some of the reasons why practice teaching cannot be allowed to just happen:

Because of its casualness and narrow scope, . . ., the usual practice teaching arrangement does not offset the unreflective nature of prior socialization; the student teacher is not forced to compare, analyze, and select from diverse possibilities. The risk is, of course, that practice teaching may simply expose the student to one more teacher's style of work. The value of practice teaching is attested to by many who have participated in it, but there is little indication that it is a powerful force away from traditionalism and individualism. It may be earthy and realistic when compared with education courses; but it is also short and parochial. (Lortie, 1975, p.71)

Clift and Brady (2005, p. 311) offered the following conclusion that we find essential in recognizing the importance of attending systematically and explicitly to the individual teacher candidates' beliefs about teaching and learning as they attend education courses and participate in practicum experiences:

Although it is well documented that prospective teachers often feel conflict among the messages they receive from different university instructors, field-based teacher educators, and school settings, it is also the case the prospective teachers resist coherent messages when they find it difficult to engage in recommended practices. When field placements reinforce and support the practices advocated by the teacher education program, individuals may still resist changing beliefs or practices because they are personally uncomfortable with the competing beliefs and practices. Practice and beliefs are mediated by their prior beliefs and experiences, course work, and current perceptions of curriculum, students, pedagogy, and other factors.

We believe that the degree of resistance to new practices is widely underestimated by teacher educators. Quite simply, teaching practices are hard to change, in part because they generate uncertainty for both the prospective teacher and for the students being taught.
We draw on Sarason's (1998) discussion of "contexts of productive learning" as a powerful way to think about educational experiences. Finally, from Nuthall's (2005) account of his journey as a researcher, we construct an image of teachers, teacher educators and researchers as potentially "lost in school," unable to see the critical features of the culture in which they carry out their work. One element of this perspective involves the traditional view that theory is first taught and then practiced (Russell, 2005). The possibility that many prospective teachers are in some sense lost in school has helped us to see more clearly what we want to avoid and what we want to achieve in our teaching and in a teacher education program. Korthagen and Kessels (1998) have highlighted the risk of emphasizing procedural knowledge over the perceptual knowledge they refer to as phronesis:

The danger of an overemphasis on procedural knowledge in teacher education is that student teachers learn a lot of methods and strategies for many types of situations but do not learn how to discover, in the specific situations occurring in everyday teaching, which methods and strategies to use. (p. 7)

We see further elaboration of the idea of being lost in school in the following conclusions drawn by Segall (2002) in a discussion of what is typically missing from teacher education classroom experiences:

Because prospective teachers are not invited to critically examine the underlying assumptions in educational conventions and practices (Kincheloe, 1993), they tend to ignore not only how those aspects impact their own education as students but also how they will structure their own classrooms in the future. As a result, ..., student teachers become more interested in learning how to perform expected actions than in analyzing those actions or the expectations that generate such actions. (Segall, 2002, p. 159)

Similarly, Bullough, Knowles, and Crow (1991, pp. 189-190) have described a need for preservice teachers

to be helped to become simultaneously students and architects of their own professional development. They need assistance to develop frameworks for thinking contextually and reflectively about their development; they need to become students of schooling and those aspects of institutional life, school practice, and interpersonal relations that are likely to enable or inhibit their development as professionals.

Working against teacher candidates becoming architects of their own professional development are the assumptions that may be held by a teacher educator:

> As teacher educators we must resist the tendency . . . to view ourselves primarily as theorists in specialist areas, leaving practice to be addressed by others or figured out by student teachers on their own. Theory and practice are inextricably connected: if we are not familiar with practical realities, we are ill-equipped to develop sound theories or teach it to others. (Kosnik & Beck, 2009, p. 9)

When Munby and Russell (1994, p. 94) analyzed the views of a group of teacher candidates, they arrived at the following insights about the authority that derives from experience:

> The basic tension in teacher education derives for us from preservice students wanting to move from being under authority to being in authority, without appreciating the potential that the authority of experience can give to their learning to teach. The challenge for teacher education is to help new teachers recognize and identify the place and function of the authority of experience. If this is not done, the authority of experience can fall victim to the danger that accompanies all versions of authority: mere possession is not enough because authority can be abused.

Becoming aware of the implications of one's teaching of children is virtually impossible without first becoming aware of the implications of how we ourselves were taught. Awareness is only the first stage in the process of making teaching explicit, because awareness immediately begs analysis, interpretation, re-thinking and action. Without awareness, one is likely to remain lost in school, oblivious to assumptions about student learning implicit in one's teaching actions. Making explicit our assumptions about teaching and learning experiences in education classrooms is an essential prelude to enacting similar analyses of practicum experiences. Once personal assumptions become more explicit, one can move on to confront more productively the dilemmas of practice and to develop the ability to see the classroom links between teaching and learning (Hiebert et al., 2007).

Following arguments offered by Loughran (2006), we used these perspectives to establish principles for a productive teaching-learning relationship. These principles would then guide our day-to-day support and supervision of candidates during their practicum placements:

- Teaching and learning must be seen as a relationship, and our relationship with each teacher candidate must be a focal point of our work.
- The tyranny of talk must be challenged by using a range of structured procedures for listening to candidates during their practicum experiences.
- We must go beyond the technical by showing teacher candidates how to situate their practicum experiences in relation to their formal education courses.
- We must see learning to teach through teacher candidates' eyes and encourage an inquiry stance toward professional practice.
- We must make the tacit explicit by acknowledging the complexities of incorporating new strategies into one's teaching and by identifying features of the school culture that make change difficult.

RESEARCH METHODOLOGY

Our modes of inquiry are qualitative, seeking emergent themes and patterns in interview and self-study data. In this paper we report two types of data. Data of the first type are drawn from a focus-group conversation with associate teachers; data of the second type are drawn from a self-study of the work of a faculty practicum supervisor. The focus-group discussion included six elementary teachers who were invited to share their perspectives on practicum learning in a 2-hour discussion structured by a set of questions. A verbatim transcript of the focus-group discussion was prepared and subjected to reading and re-reading by several individuals to identify points of convergence and divergence. Data were coded to establish categories and methods of constant comparison were used to identify themes and patterns in the focus-group data. The self-study portion of our study attended to guidelines for quality in self-study research outlined by Bullough and Pinnegar (2001). We took particular note of the following point:

> Quality self-study research requires that the researcher negotiate a particularly sensitive balance between biography and history. While self-study researchers acknowledge the role of the self in the research project, such study does not focus on the self per se but on the space between self and the

practice engaged in. There is always a tension between those two elements, self and the arena of practice, between self in relation to practice and the others who share the practice setting (p. 15)

We believe that two quite different types of data related to quality of practicum learning experiences provide complementary perspectives on a complex and challenging issue.

DATA
Insights from a Conversation with Associate Teachers
Four themes, each with sub-themes, emerged from analysis of the focus-group data.

1. The teacher candidate's teaching persona is crucial.
   ♦ Park your ego at the classroom door. The practicum is a humbling experience.
   ♦ Be collegial—teaching is a political business.
   ♦ Learn as much as you can, then share it with others in classes.
2. Early and energetic engagement in the practicum setting is imperative.
   ♦ Show initiative. Be willing to engage, and be willing to rise from the ashes when you crash and burn.
   ♦ Connect with kids, even the ones you don't like or understand; challenge and engage the students.
3. The contexts of classroom, school, curriculum, and parents are just as significant as the context of the university program itself.
   ♦ "School-university partnership" is so much more than the countless details of what the university expects when it sends teacher candidates to schools that agree to receive them.
   ♦ Teachers and teacher educators must share the big picture of helping candidates learn to teach by learning from experience.
   ♦ The theory-practice gap is more complex than we thought. So many daily responsibilities of teachers and faculty are invisible unless one is personally present and enacting them. Practical responsibilities can become all-consuming in an environment that offers few opportunities to focus on the big picture as well.
4. The teacher candidate's relationships with students, associate teachers, and university supervisor are central to productive practicum learning.
   ♦ Collegiality is essential at every level.
   ♦ Share with everyone, learn from everyone.
   ♦ The practicum is not about associate teachers transmitting a set of directives from the university. Productive practicum learning requires constructive relationships among candidates, associate teachers, and faculty supervisors. Productive practicum learning also requires a dynamic process in which associate teachers and faculty supervisors meet as colleagues with the shared purpose of assisting and guiding the teacher candidate.

Each teacher candidate, associate teacher, and faculty supervisor is unique and speaks from both beliefs and experiences. Learning to do well in the practicum setting has little in common with learning in a university classroom, if that classroom focuses narrowly on transmitting elements of a professional knowledge base for teaching. In the practicum there are no right answers, only complexities and puzzles that have the potential to provoke conceptual change if those learning to teach are open to learning from students, teachers, and teacher educators.

Feiman-Nemser and Remillard (1996, p. 78) framed the challenge thoughtfully:

> We have separated the "what" from the "how" of learning to teach in order to focus on the question of what teachers need to learn. Ultimately, content and processes of learning to teach must be brought together, since how teachers learn shapes what they learn and is often part of what they need to know. Unfortunately, we know even less about the processes of learning to teach than we do about the content.

Our particular interest is in better understanding those learning processes as well as improving their quality. By listening to six associate teachers, we were reminded of the importance of humility on the part of everyone involved in learning from practicum experiences. Helping people learn to teach is *not* about demonstrating how much we know about teaching; helping people learn to teach *is* about putting our own on-going professional learning at the service of those just beginning the required unlearning, learning and

relearning. Similar conclusions emerged from the self-study of the activities of a faculty supervisor interacting with teacher candidates and associate teachers.

Insights from a Faculty Supervisor's Self-Study

In a self-study of his own work as a supervisor of teacher candidates' practicum experiences, Russell (2002) attempted to understand the consequences of a new program structure that made significant changes to the traditional expectations for the role of faculty supervisor.

> The central question that emerged for me was: *"How can I help each candidate improve the quality of professional learning during the early extended practicum?"* Although this central question focuses on candidates, a second question was always prominent: . . . *"How can I help to improve the quality of the professional relationship between this school and the Faculty of Education at Queen's University?"* My self-study, then, is based on an action research design with a view to documenting and understanding each individual's experiences of learning to teach. (p. 77, emphasis in original)

The process of studying his own behaviour in a role that involves at least 30 individuals (associate teachers and teacher candidates) in one school helped Russell realize how easy it is to take events for granted. Self-study opened his eyes to the complexity of the new program structure and the many dimensions of improving the quality of practicum learning.

> With the clarity of hindsight, I realize that there were many moments when I tended to assume that simply *being in the school* was the basic requirement for success in the new role, in the eyes of those learning to teach and in the eyes of the experienced teachers to whom the teacher candidates were assigned. Personal experience and self-study of that experience have taught me how much more complex the matter is. We continue to tinker with the structure as we also attempt to re-examine and re-define its underlying assumptions and our collective beliefs about learning to teach. Predictably, teacher educators are no better at changing their practices than are teachers anywhere else. (p. 74)

The gathering of data from those he was supervising led to the following challenges to familiar assumptions:

> This self-study has forced me to reconsider my early premise that visits to schools to observe pre-service candidates are, in and of themselves, valuable to all concerned. School visits are made with the best of intentions, yet we have little evidence of the impact of a faculty member's school visits on candidates' professional learning or on the school-university relationship. We would be foolish to assume that visits are good, in and of themselves. Spending more time in schools does not automatically contribute to candidates' professional learning, but *time spent in schools is a fundamental base on which broader goals and relationships can be constructed.* (Russell, 2002, p. 84)
>
> While experience is powerful, learning from experience is far from automatic, perhaps because all levels of formal schooling pay little attention to learning from experience. Candidates' initial mindsets now seem even stronger than I realized. (p. 84)

Richardson-Koehler (1988) captured several familiar features of the supervisor's role in words that continue to ring true:

> The role of the university supervisor is ambiguous at best, and that role in relationship to the expectations for the cooperating [associate or mentor] teacher is even more confused. . . . The degree to which the university supervisor can affect the classroom practices of student teachers, given the structure of the experience, is questioned by supervisors themselves . . . Like the supervisors in an earlier study that I conducted, . . . I felt that as a supervisor I was not affecting the student teachers' classroom practices very much, at least in comparison with the cooperating teachers. Short observation and feedback sessions once every two weeks do not constitute adequate supervision. . . . I therefore began to describe my role as that of supervising a process, rather than the student teachers. . . . A discussion of routines constituted a potential criticism of the cooperating teacher's performance (Richardson-Koehler, 1988, p. 32).

In other words, the familiar practice of short bursts of observation and discussion is inadequate. Familiar school routines are not about exploring the big picture. Initiating and supporting productive learning from practicum experiences requires us to unlearn familiar practices in order to invent new supervisory practices that centre on the process of learning from experience. In this vein, Russell's self-study concluded as follows:

> My most compelling insight is that teacher candidates, experienced teachers, and faculty liaisons can be expected to approach supervisory interactions with "default" assumptions driven by unexamined personal experiences. At the outset, self-study is a way to bring such assumptions to the surface; over time, self-study is a way to keep one's focus on the goal of extending our professional understanding of what it means to learn from experience in the classroom and school settings. With that long-term end in view, genuine partnerships may emerge from a base of significant time spent with candidates and experienced teachers, unpacking not only observations of candidates' teaching but also our fundamental premises about teachers' professional learning. (Russell, 2002, p. 86)

CONCLUSION

Data from the perspectives of associate teachers and a faculty supervisor as well as focus-group conversations with teacher candidates (Martin & Russell, 2005) lead us to suggest that promoting quality in practicum experiences is far more complex than our everyday assumptions would suggest. We all approach the practicum experience with traditional assumptions of which we are typically unaware until dissonant experiences compel us to notice and examine our assumptions. Program re-structuring generated many new expectations as well as new challenges. As expectations failed to materialize and as challenges proved to be more complex than anticipated, we were forced to re-examine our own practices and to move beyond the default perspectives of teaching as telling and learning as listening. We have no simple recipes, but we have far greater understanding of the reasons why promoting quality in practicum experiences continues to be an elusive yet profoundly important goal. A conceptual change approach that supports many new pedagogical strategies often recommended to new teachers raises major challenges, given that a basic structural premise of many teacher education programs is that new strategies are first learned in university classes and then practiced in school placements. *Until teacher education programs come to terms with the fundamental importance and authority of experience for all types of learning, their structures are likely to contradict their research-based premises and rhetoric, leaving candidates continuing to overlook or discount what they could, with teacher educators' support, be learning from practicum experiences.*

Our efforts to inquire into our own practices and experiences and to listen to teacher candidates and associate teachers on the topic of improving the quality of practicum learning have generated the following action plan:

- Challenge directly and powerfully the implicit, unexamined assumptions of teacher candidates about how they learn from experience and about how they make sense of their previous school history (Lortie's "apprenticeship of observation").
- Expose the cultural myths that prevent new teachers from making sense of classroom routines and interactions (Nuthall, 2005, p. 918).
- Acknowledge the inherent and necessary complexity of becoming a teacher (Darling-Hammond, 2006, pp. 38-40).
- Recognize that a candidate in a preservice program necessarily follows a trajectory that requires a long-term perspective on practicum learning (Clift & Brady, 2006, p. 331).
- Challenge our implicit assumptions about the nature of school-university partnerships, assumptions that can compromise efforts to support productive practicum learning.
- Create opportunities for on-going dialogue among associate teachers and faculty supervisors about the nature of professional learning and the process of learning to teach.

350 - Efficacy Beliefs at School: Perceptions of Principals, Teachers and School Collective

Daniela Couto Guerreiro Casanova

Universidade Estadual de Campinas
danielaguerreiro@yahoo.com.br

Abstract: This research starts from the assumption that principals with a strong sense of management efficacy will contribute to the establishment of strong perceptions of school collective efficacy and teacher self-efficacy, resulting in a higher rate of school performance. As a general objective it is intended to analyze and explore the relationship between teacher self-efficacy, principal self-efficacy, school collective efficacy and school performance recorded by the Index of Development of Education of the State of Sao Paulo, Brazil. Participants in this research will be teachers and principals of public high school located in São Paulo, Brazil. Data collection instruments used include: Questionnaire of Characterization, Teacher Self-efficacy Scale, Principal Questionnaire and Collective Efficacy of Teachers Scale. The data analysis will be conducted through descriptive, correlation analysis, ANOVAs and path analysis. This research seeks to contribute to enhancing knowledge about efficacy beliefs in school, still incipient in Brazilian literature.

Keywords: self-efficacy; collective efficacy; high school; motivation

INTRODUCTION

This paper is a brief presentation of the *Eficácia Individual e Coletiva de Docentes e Gestores no Ensino Médio Paulista* research piece*,* still in development. This research starts from the assumption that the manager with a strong sense of management efficacy will contribute to the establishment of high school perceptions of school collective efficacy and teacher self-efficacy, resulting in a higher rate of academic achievement and aims to examine and explore the relationships between teacher self-efficacy, principal self-efficacy, school collective efficacy and school performance recorded by the Index of Development of Education of the State of Sao Paulo, Brazil. The individualized teaching culture hinders the collective work necessary for the effective implementation of the Curriculum Guidelines for High School (Zibas, Tartuce & Ferretti, 2006). This seems to be minimized in schools with stronger identities, which leaders and faculty are recognized as committed. These aspects are considered as facilitators for the implementation of projects, involving administrators, teachers and students, consisted with the curricular of secondary school. The Social Cognitive Theory (Bandura, 1997, 2008), namely in the concepts of school collective efficacy, teacher self-efficacy and principal self-efficacy, has portrayed contributions to understanding the teaching-learning scenario in high school.

In Brazil, a considerable amount of research conducted from the perspective of Social Cognitive Theory in educational contexts is about the field of teaching self-efficacy (Bzuneck, 1996, 2000; Iaochite, 2007; Macedo, 2009; Rocha, 2009; Azzi, Polydoro & Bzuneck, 2006). These research pieces have highlighted the need to investigate the school collective efficacy construct (Azzi & Rocha, 2010; Bzuneck & Guimarães, 2009, Iaochite, 2007; Rocha, 2009; Russo & Azzi, 2010), since the teacher does not act alone in the environment education, but integrates an institution formed by teachers, administrators and staff. They have also highlighted that high perceived self-efficacy has been related to teacher perceptions about support provided by their principals (Iaochite, 2007; Macedo, 2009).

The Self and Collective beliefs

Teacher`s Self-efficacy beliefs are defined as "a judgment that teachers make about their own capabilities to achieve desired results for student learning and engagement, even among those that may be difficult or unmotivated" (Tschannen-Moran & Woolfolk Hoy, 2001, p.783). The Teacher`s Self-efficacy beliefs has been related to: teacher's behavior in the classroom, the effort invested in the education process, the establishment of the goals of teachers, an openness to feedback, the persistence of teachers, the highest levels of lesson planning and teachers organizations, the greater tolerance for students who have made mistakes, the greater dedication to teaching designed for students with learning difficulties, the performance of a more humanistic approach in the control of the student and the administration of conflict, greater willingness to

implement new teaching practices, conscience of the teacher's responsibility for student learning, friendly and attentive behavior dedicated to students, establish a positive environment to promote learning and the promotion of better student performance in various disciplines, supporting autonomy of students, the value of academic tasks, the stimulation of the student's academic self-efficacy beliefs, stimulation of student motivation, general enthusiasm, commitment and satisfaction with the teaching profession (Tschannen-Moran & Woolfolk-Hoy, 2001; Azzi, Polydoro & Bzuneck, 2006, Bandura, 1997; Bzuneck, 2000; Iaochite, 2007; Azzi & Polydoro, 2010) and the time spent in the teaching profession (Rocha, 2009). Research shows that the school principal plays a role of great importance in order to contribute to perceptions of school collective efficacy (Azzi & Rocha, 2010; Caprara et. al. 2003; Tschannen-Moran & Barr, 2004). The information presented by Caprara and collaborators (2003) points out that school collective efficacy is related to educational judgments that teachers have in relation to managers, whose perception had the highest correlation (0.41) with the variable school collective efficacy. Some researchers highlight the need to investigate the relationship between the principal and the school collective efficacy (Goddard, Hoy &Hoy, 2000; Hoy et al., 2002)

The belief of collective efficacy is defined as a group shared belief in their joint capabilities to organize and execute courses of action required to produce certain levels of tasks (Bandura, 1997). Caprara and colleagues (2003, p.16) highlight the belief that collective efficacy "refers to the judgments that people make about a social system (family, team, organization or community) and their level of performance and effectiveness in specific areas shares". The group function is a product of interactivity and dynamic actions of its members, which creates an emerging belief that "it is more than the sum of the individual attributes of each member" (Bandura, 1997, p.478). It is built through direct experiences, vicarious experiences, social persuasion and perception of physical and emotional states. The collective efficacy belief is not static and can therefore change over time.

In the educational context, perceptions of School Collective Efficacy has been defined as the judgments of teachers from a school whose faculty are capable to organize and execute courses of action required to achieve positive results with students (Goddard, Hoy & Hoy, 2004), promote learning and stimulate academic self-efficacy and self-regulating learners (Bandura, 1997). Thus, school collective efficacy can be understood as the perception of faculty about their own ability to achieve certain goals (Goddard & LoGerfo, 2007) and deal with specific tasks to teaching (Adams & Forsyte, 2006), in order to make a difference to promote learning and student achievement (Hoy et. al., 2002) .

The literature's analysis verified that the results of investigations carried out have emphasized the mediating role of school collective efficacy belief for school performance (McCoach & Colbert, 2010; Goddard, Hoy & Hoy, 2000; 2004; Goddar & LoGerfo, 2007; Hoy et. al. 2002; Parker, Hannah & Topping, 2006; Skaalvik & Skaalvik, 2007, Tschannen-Moran & Barr, 2004) and motivation of students (Hoy et. al. 2002; Skaalvik & Skaalvik, 2007). According Goddard, Hoy and Hoy (2004) this can be explained by theoretical understanding, which provides that a robust belief in school collective efficacy contributes to the establishment of expectations for success, helping those involved to be resilient in order to achieve their goals. Moreover, the belief that school collective efficacy can have great influence on teaching efficacy belief, especially for the tasks of teaching (Caprara, et. al. 2003; Goddard, Hoy & Hoy, 2000; 2004; Skaalvik & Skaalvik, 2007 ; Tschannen-Moran & Barr, 2004) and in the motivation of teachers (Hoy et. al., 2002). It has also been found that school collective efficacy is positively related to educational differences in perceived effectiveness of individual teachers between schools (Goddard, Hoy & Hoy, 2004). The school collective efficacy has been shown to be the strongest predictor of teacher's self-efficacy among schools, so the more the faculty of a school judged themselves collectively effective, more members believe they are self-efficacy as teachers. The largest possible participation of teachers in the process of choosing teaching materials, as well as in shaping the educational policies of school units, has been related to higher perception of school collective efficacy (Goddard, Hoy & Hoy, 2004).

Regarding emotional aspects that permeate the work relationship in educational institutions, research found significant results. It may be noted that the school collective efficacy serves to encourage some behaviors and discourages others (Goddard, Hoy & Hoy, 2004), and that trust in peers is positively related to perceived school collective efficacy (Goddard, Hoy & Hoy, 2000). According to Caprara and colleagues (2003) the school collective efficacy is directly related to affective commitment to the school unit in which the teacher works, as well as satisfaction with teaching. Thus, the school collective efficacy may contribute to decreased perception of pressure resulting from job tasks (Goddard, Hoy & Hoy, 2000; Skaalvik & Skaalvik, 2007) and burnout (Skaalvik & Skaalvik, 2007).

Specifically aimed at teaching tasks, research has shown that the high perception of school collective efficacy belief helps to direct the school teacher behavior (Tschannen-Moran & Barr, 2004). Behaviors that

are influenced by the belief of the faculty include setting high and appropriate goals and how to overcome problems and failures which are related to students persistence (Hoy et. al., 2002).

As implications, research indicates that: (1) to improve the performance of students, they should be encouraged to develop school collective efficacy (Goddard, Hoy & Hoy, 2000; Adams & Forsyte, 2006; McCoach & Colbert, 2010; Hoy et. al., 2002), (2) intervention programs should be conducted to promote school collective efficacy in order to optimize the operation of school (Caprara, et. al. 2003; Goddard, Hoy & Hoy, 2000; Goddard, Hoy & Hoy, 2004; McCoach & Colbert, 2010), (3) the school collective efficacy should be built through the sources of direct experience and social persuasion, using intervention projects specially designed for this purpose, emphasizing the importance of principals as agents responsible for this task (Caprara, et. al. 2003; Goddard, Hoy & Hoy, 2000; Goddard, Hoy & Hoy, 2004; McCoach &Colbert, 2010), and (4) the school collective efficacy must be stimulated through vicarious experience, by analyzing other schools that could be considered models, which have similar goals and structures (Caprara, et. al. 2003; Goddard, Hoy & Hoy, 2000; Goddard, Hoy, Hoy, 2004) as well as through videos, which provide guidance on school collective efficacy (Goddard, Hoy & Hoy, 2000).

METHOD

After approval by the Committee of Ethics in the Research and Regional Board of Education, contact with the high schools will be established. Schools will be selected taking into account the Education Development Index of the State of Paulo. The population in this study will consist of teachers and administrators of state run schools that work at high schools, located in São Paulo. This research will be conducted with a sample composed of 10 high schools, with the estimated participation of 240 teachers and 30 administrators (principals and vice principals). The data collection will be held during the weekly pedagogical meetings. All data will be collected with the presence of researchers, which will guide the participants not to exchange information regarding the instruments used in research during the time of applying them in order to ensure the reliability of responses. In addition, participants will receive a guarantee under the secrecy of the answers, as well as ensuring that the answers will be used solely as a means of research.

This research will use as materials for data collection: (1) questionnaire of characterization, which seek information on participants, such as age, length of the teaching profession, type of training, type of employment, time devoted to the journey work, among other personal characteristics, (2) Teacher Self-Efficacy Scale (Polydoro et al. 2004; Tschannen-Moran, Woolfolk Hoy, 2001), which will be used to identify the perceptions of teachers regarding their beliefs of teaching efficacy. The scale has internal consistency of 0.937 and explains 54% variance in the construct studied, consisting of 24 items, Likert 1-6, arranged in two factors: Efficacy as *intentionality of teachers' action* and *effectiveness in managing the class*, (3) Principals'' Questionnaire (Tschannen-Moran & Gareis, 2004), which will be held by the identification of perceived self-efficacy of managers, to be translated, adapted and validated for the Brazilian reality. This scale has 18 items in Likert format from 1 to 9, organized into three factors called self-efficacy to manage (explained variance 41.12), self-efficacy for instructional aspects of the director (explained variance 51.84) and self-efficacy for moral leadership (explained variance 59.64) and (4) Collective Efficacy of Teachers (Tschannen-Moran & Barr, 2004), used to identify the perception of collective efficacy of teachers and administrators. This scale will be translated, adapted and validated for the Brazilian reality. There are 12 items in Likert format from 1 to 9 and internal consistency of 0.97. It is structured in two factors with six items each, called instructional strategies (internal consistency of 0.96) and disciplined students (internal consistency of 0.94). It is noteworthy that the authors have already authorized the use and adaptation of scales cited.

Data Analysis Plan

Data analysis will be performed using quantitative analysis, aiming to measure these variables as well as to verify and characterize their possible relationships. Descriptive analysis will be used to characterize the sample and the presentation of the results obtained by means of scales. The descriptive analysis will included the frequency, mean, minimum and maximum values for each response to the participants. The scales will be considered by factor and by the totality. Correlation analysis will be performed between variables. To analyze the difference between the averages for each school ANOVA will be used, in which the school unit shall be considered as an independent variable. Path analysis will be used to test this research's hypothesis.

CONSIDERATIONS

As might be perceived by the studies mentioned previously, the school collective efficacy presents itself as an important variable for school change processes. Although some studies point out that the school collective

efficacy is related to school socioeconomic status, so that schools with more needy students show low school collective efficacy (Goddard & LoGerfo, 2007; Hoy et.al., 2002), there are results that indicate that school collective efficacy is independent of socioeconomic status (Tschannen-Moran & Barr, 2004). The fact that school collective efficacy can change, by means of intervening actions, is the mainstream aspect in this discussion. Thus a school initially identified with low perception of school collective efficacy can experience a process of mobilization and build a new school perception of collective efficacy, stronger, able to help improve the performance and motivation of its' students. For educators to promote this change is less complex than changing the socioeconomic status of the school community in which they operate (Goddard & LoGerfo, 2007; Hoy, et.al. 2002; Tschannen-Moran & Barr, 2004). In order to achieve such a mobilization, intervention strategies for enhancing perceptions of efficacy at school should be performed to develop teacher professional competence and rekindle the motivation and enthusiasm, considering teachers as a social group that seek to recover their sense of social commitment (Bzuneck & Guimarães, p. 12, 2009). This emphasizes the considerations of Russo and Azzi (2010), who warn of insufficient research on the school collective efficacy in the Brazilian reality, as well as the contribution that the propositional models of integrating more than one dimension of the phenomenon education can take to promote the coordination of individual actions with the collective effort in order to improve the process of construction and development of the education program of the school unit.

Given the above, it is possible to realize the need to investigate the contribution of school collective efficacy and its relationship with teacher self-efficacy and principal's self-efficacy, especially in the Brazilian reality. It is believed that this research may help broaden the understanding of all variables. Moreover, considering the theoretical organized here, it is believed that this research will be able to contribute to the dissemination of knowledge about the efficacy beliefs at school.

THEME 3
Learning Communities and Networks

40 - Service-learning as a Model for Establishing Partnerships between Student Teachers and their School Communities: Opportunities and Challenges

Michèle Stears

University of KwaZulu-Natal, South Africa
stearsm@ukzn.ac.za

Abstract: The purpose of this paper is to present a model implemented at a South African university to assist the institution in developing a closer relationship with the community through science education. This model is defined as service-learning and was implemented through a teacher education programme. Kolb's experiential learning theory (ELT) is the lens through which the research is conducted and is conceptualised as Kolb's experiential learning cycle. The particular science education module selected is a method module in Biology Education. The service-learning component of the module was the design of an environmental policy by the student, in collaboration with the school. Evaluations by students revealed that they experienced the process as being more of a personal and social benefit than academic benefit, while teachers' evaluations revealed that they felt that students had made sufficient effort to understand the context of the school and that the audit students conducted were realistic and captured the environmental conditions of the school correctly. This model is appropriate for establishing working relationships with schools as the participants collaborate with a view of improving the community. A number of challenges were identified; most of which stemmed from the fact that very little opportunities exist for the implementation of service-learning into programmes in higher education institutions. However, in spite of these challenges opportunities do exist for incorporating service-learning into an existing module and programme.

Keywords: Partnership; community; service-learning; science teacher education; environmental policy.

INTRODUCTION

One of the challenges facing Higher Education in South Africa is the way in which Higher Education institutions interact with the communities in which they are situated. Traditionally universities focused on research and teaching, with little attention being paid to community involvement. In the light of transformation of Higher Education institutions, service to the community has gained more prominence. However the question is raised as to how this service is to be enacted.

This paper discusses the integration of a model of community engagement referred to as service-learning into a module that is part of a teacher education programme. The module referred to is a science education module and it demonstrates how service-learning may be used to create partnerships between communities and universities. Opportunities that arose from this integration, as well as the challenges that threatened the initiative are explored. The notion of service-learning as a model of community engagement in teacher education is not widely known or practiced in South Africa, but local interest is growing and this reflects international trends (Castle & Osman,2003).While the incorporation of this model of service-learning provides opportunities for students to engage with communities in ways that enhance their personal growth and develop social responsiveness, a number of challenges with regard to implementation emerged during the course of developing the module.

The questions addressed in this paper are:
- How does service-learning enhance the establishment of partnerships between a university and schools?
- What challenges and opportunities emerged when integrating service-learning into a science education programme?

THEORETICAL FRAMEWORK AND LITERATURE REVIEW

The pedagogical foundation for community engagement is experiential education as it informs the design and delivery of various training events (HEQCOM, 2006). David Kolb's experiential learning cycle is an appropriate learning theory for community engagement as it views experiential learning as the process that links education, work and personal development. This concept as developed by Kolb, 1984 (HEQCOM, 2006) views learning as a cyclical pattern from experience through reflection to conceptualising and action,

returning to further experience. This theory of experiential learning has been adapted and applied as a process model in numerous fields and training endeavours.

While experiential learning may form the pedagogical foundation for community engagement, the theories of constructivism underpin community engagement as well. Learning occurs at best if it is grounded in the learners own experience. John Dewey's view of education contributed to the pedagogy of service-learning as it emphasised the link between experience, learning and society, (HEQCOM, 2006.) In formulating his model of experiential learning Kolb drew on the work of Dewey. At the heart of Kolb's model is a simple description of how experiences is translated into concepts that can be used to guide the choice of new experiences (Atkinson & Murrel, 1988).

The experiential learning discussed in this paper is a form of community engagement that is underpinned by a conceptual framework where the learning is situated midway between the beneficiaries(community and student) and where the goal is located midway between service and learning. Furco (1996) describes this model as Service and Learning goals of equal weight and each enhances the other for all participants. In his view service–learning only occurs when both the providers and recipients of service benefit from the activities. Service-learning, as applied in this study, is underpinned by Dewey's model of linking knowledge and experience, individuals with society and reflection with action (O'Brien,unpublished).

One of the challenges in implementing service-learning in the curriculum is the disagreement as to what service-learning really is. It is useful to define service-learning in this context and to distinguish it from other models of community engagement such as volunteerism, community service, internships and field education:
A substantial body of research reports on the outcomes of service-learning courses in higher education. Research on the outcomes of service-learning in a political science module revealed that students emphasised their learning with regard to the communities they worked in with a significant effect on values, but at the same time achieving some academic learning as well (Marcus, Howard &King, 1993). Eyler, Giles and Braxton (1997) report on research that showed positive development of students' attitudes, values and a better understanding of social issues. Van Wynsberghe and Andruske (2007) report that service-learning contributed both to development of students' discipline concepts as well as to their understanding of community issues. In addition students were willing to engage in service-learning again. One approach to service-learning is educating students for life rather than a career. Service-learning should enrich communities, while the academic component is optional (Bringle & Hatcher 1996). Within the South African context Castle and Osman's research explored various models that could guide institutions to develop service-learning and concluded that service-learning, combined with school experience, is an appropriate way to prepare students for the professional demands laid down in national policy on teacher education (Castle & Osman, 2003).This approach could simultaneously contribute to the student's career as it would build capacity with regard to the future teacher's pastoral role- one of the 7 roles of the teacher as set out in the Norms and Standards for Teacher Education (2000).

A substantial number of researchers in the field of service-learning, irrespective of the specific models applied, emphasise the importance of reflective practice. Deep reflection is essential for service learning to be effective. A lack of deep reflection often results in reinforcement of stereotypes, the support of presuppositions and a failure to critically guide future action (Hatcher & Bringle, 1997). Students should be able to meaningfully consider their service experience in the light of the curriculum. While reflection has traditionally not been an integral part of tertiary pedagogy, service-learning creates the opportunity for reflective practice.

The purpose of this paper is to present a model implemented at a South African university to assist the institution in developing a closer relationship with their communities through science education and to present the challenges and opportunities that arose in the design and implementation of the model.

CONCEPTUALISATION OF THE COURSE

Within the context of transformation, academic staff at the institution where this model was implemented are encouraged to engage with communities, but few structure are in place to facilitate this process. When the decision was made to include service-learning in the science curriculum with the view of establishing a relationship with the community, several options were explored which would facilitate the process.

The fact that the pedagogy of service-learning emphasises socially responsible and responsive teaching, research and service activities (O'Brien,unpublished), made it the logical choice for integration into the teacher education module discussed here. Of the five models of service learning defined by O'Brien the approach used in the design of this module most closely resembles the Pedagogical Discourse Model. This model foregrounds knowledge as teaching and learning. In this model service-learning becomes one of a number of learning and teaching activities within an accredited university module. This model made it

possible to integrate service-learning with content from an existing module. The result is a module that is 70% service learning and 30% original content. The service learning in this module is therefore of necessity defined within the framework of the curriculum for Biological Science Method as well as within the framework of the B.Ed curriculum. Knowledge acquired and skills developed are related to the teaching of Biology (the specialist role of the educator), as well as to the educator's pastoral role. As a science education module, the focus has to be on the pedagogical content knowledge required to teach Biology/Life Sciences at senior school level.

As one the critical outcomes of the South African curriculum states that learners should demonstrate an understanding of the relationship between science and society and one of the Learning Outcomes of the Life Sciences curriculum states that learners should demonstrate an understanding of the interrelationship between Science, Technology, Indigenous knowledge, Society and the Environment, an understanding of Environmental Education is a crucial element of Life Sciences education.(National Curriculum Statement, 2003). Based on this premise, the service-learning component of the module was the design of an environmental policy by the student, in collaboration with the school.

Although the acquisition of knowledge and skills is central to the pedagogical discourse of community service-learning, strong emphasis was placed on the promotion of personal growth and social responsibility. This approach has an impact on the curriculum as it stimulates thought about changing the curriculum. It also sets up a new relationship between the institution and the community that gives the curriculum a dynamic quality. Students bring something back into the classroom.

One important aspect that was included in the redesign of this module, was that of reflective practice. Reflection is used to actualise service and learning (HEQCOM, 2006). Not only does reflection serve to develop students with regard to their personal growth and development of social responsibility, but it links learning outcomes and assessment. Students reflect on their practice and on their achievement of Learning Outcomes. This reflection is not a superficial activity, but is assessed to determine whether service-learning outcomes have been met. Reflection in this context should be a structured reflection, where students reflect intentionally and in the process analyse concepts, evaluate experiences and postulate theories. Critical reflection provides students with the opportunity to examine and question their beliefs, opinions and values. It involves observations, asking questions and putting together facts, ideas and experiences to derive new meaning (HEQCOM, 2006). Hatcher and Bringle (1997) describe deep reflection as having 4 stages: linking experience to learning objectives, being guided, occurring regularly, allowing feedback and assessment and lastly, the clarification of values. The purpose of this structured reflection in service-learning is to promote the development of the whole person. In this process the feelings of each individual is validated. For instance individuals who are discouraged during this experience need to share their feelings and realise that they are not alone (Axt, 2007). By reflecting on their practice in this way, it was envisaged that students' personal growth would contribute to their development as professionals who are able to take on the pastoral role of the educator with greater confidence than before.

DEVELOPMENT OF THE COURSE
A number of aspects were considered in the process of integrating service-learning into an existing module.

Design
Once the purpose of service-learning in a science education module was established, the task of designing a module incorporating service-learning began. First the main outcomes of the module pertaining to service–learning were defined. They were:

With regard to academic learning
- Development of an environmental policy for a school
- Development of a Learning Programme on the theme 'environment'

With regard to personal growth
- Working in a team
- Collaboration skills
- Development of reflexive skills

With regards to social responsibility
- Understanding their responsibility to engage in a broader context with schooling communities
- Developing responsible environmental behaviour

The environmental policy included a section which assisted teachers in using the curriculum to teach environmental education. In this regard, students were advised to develop a short leaning programme in which they demonstrated the possibility of integrating Environmental Education in the curriculum. The outcomes pertaining to personal growth and social responsibility were outcomes that could be developed by engaging with the community. In this context the community was the school where the student was placed during the school experience period.

As mentioned earlier, students are familiar with the concept of experiential learning. As student teachers they are required to spend a number of weeks each year in a school. However this form of experiential learning benefits the student much more than the schooling community. It was therefore essential that students develop an understanding of service-learning as an activity that happens outside the classroom and benefits the community to the same extent as the student. The service–learning built into this module therefore serves to develop students in terms of their personal growth and their responsibility to society as teachers, as well as serving to develop their understanding of integrating Environmental Education into their teaching –inside and outside the classroom. Academic learning and service to the community therefore underpin the learning in this module. Environmental Education is used as the focus of the community service. Students design an environmental policy for a school, serving the school community by facilitating the establishment of an environmental committee and conducting an audit of the school environment.

Implementation

The first step in the process was to meet with the school principal to establish a relationship between student and school. The notion of service-learning was discussed with the principal. Although the general thinking was that principals would welcome the initiative as it would benefit the school community, it was deemed prudent to ask permission to conduct an audit of the school environment. Principals were also asked to assist the student in establishing a committee consisting of teachers and students who would work collaboratively in developing an environmental policy for the school. The student facilitated the appointment of an environmental coordinator who was requested to convene an environmental education working group that could initiate the development of an environmental policy. Documentation that serves as a guideline for the development of an environmental policy was supplied by the lecturer who taught the course. The important aspect that needs to be emphasised here is that the policies that students designed were based on the available resources at their respective schools and not some idealised version of what we think an environmental policy should be. Students conducted an audit of the school environment, identifying strengths and weaknesses. The policy was drafted using the schools' strong points as the main focus. Together with the committee, decisions were taken, based on the needs of the school community, as well as the available resources in the school. The policy clearly demonstrated that the environment is not only the biophysical environment but includes the socio-cultural, economical and political environment as well.

Reflection and assessment

Students were briefed as to the nature of the reflection required of them. To facilitate this, students were required to keep a reflective journal throughout the course. While critical reflection was assessed in a number of ways, academic learning also needed to be assessed. Assessment of tasks, assignments, an environmental audit and the final environmental policy gave an indication of students' academic learning. In summary, comprehensive assessment included formative assessment in the form of reflections, tasks and assignments, while summative assessments included a final environmental policy, including a short learning programme of environmental activities in the curriculum.

Evaluation

On completion of the module students were asked to evaluate the module. Students generally believed that they benefited from the experience of engaging in service-learning. It is significant that most students experienced the process as being of personal benefit rather than academic benefit. They felt they could apply their knowledge in a new context, demonstrate some confidence in the improvement of their academic knowledge in spite of the fact that they appeared to think that the process had more social benefit. This may be due to the fact that students, for the first time, engaged in a process that allowed for social and personal development on such a scale. It is significant though that a number of students placed more value on the process that allowed them to become involved with the school community. The fact that most students thought that the site they worked in was appropriate is most probably an indication that this project could be initiated at any physical site. The majority of students reported that they believed the teachers who were

involved in the project developed a better understanding of environment, while three expressed their uncertainty whether teachers had developed a better understanding.

Teachers were requested to complete an evaluation form as well. They were generally satisfied with the students' level of understanding of the concept of service-learning. They were satisfied that most students had made sufficient effort to understand the context of the school and returned after teaching practice to follow up on a number of issues. Most teachers were also satisfied with the audit students conducted; judging it to be realistic and capturing the environmental conditions of the school correctly. Following this, most of them were confident that students were able to develop an environmental policy for the school that was practical and could be implemented by the school community.

OPPORTUNITIES AND CHALLENGES

By incorporating service-learning in a science education course, the opportunity arises to promote personal growth and social responsibility through science learning. Where science education traditionally focused on the specialist role of the educator, service-learning provides the opportunity for science education to contribute to the pastoral role of the educator as well. In this way science education is able to contribute to the holistic development of the educator in a more meaningful way. While developing their knowledge and skills pertaining to science education, they are able to reflect on their roles as educators in a broader community and in particular their roles of agents of change in that community. By becoming involved in this way, student teachers play an important role in establishing a firmer relationship between the university and the schools in the community

While the opportunity exists to incorporate service-learning in a meaningful way in science education programmes, one cannot ignore the challenges that impact on meaningful incorporation. One such challenge is the structure of programmes and curricula at Higher Institutions. This structure prohibits the introduction of new courses and modules in the short term. The only option is to incorporate service-learning in existing modules as described in this paper.

A further challenge is the involvement of management of Higher Education Institutions. Faculty at this point in time does not provide any support. For it to be successful, support from management is important. In the USA for instance, a tremendous amount of resources have been made available in higher education (Bowley & Meeropool, 2003). At this point in time very few Higher Education Institutions have paid much more than lip service to the concept of service-learning.

The establishment of permanent partnerships is also a challenge within the context of teacher education. The most appropriate partnerships are schools, but this type of partnership is seldom permanent as students are required to experience different schools and are therefore in a difficult position to build long term relationships with schools.

For service –learning to be successful, it is important for schools to buy in to the process as willing partners. Experience has shown that schools often view new innovations with suspicion, especially if it involves commitment from teaching staff. Convincing all staff that service-learning will benefit the schooling community remains one of the main challenges in this endeavour.

CONCLUSION

In this paper I have argued that the model of community engagement that is most appropriate in teacher education is that of service-learning as it makes it possible to distinguish between school experience as a form of internship and service-learning as benefiting both students and community equally. The model of service-learning applied in the development of the module described here is the Pedagogical Discourse Model which foregrounds knowledge as teaching and learning. This model is most appropriate as service-learning was incorporated within the constraints of an existing module where academic content was important within the context of science education. The model is also appropriate for establishing working relationships with schools as the participants collaborate with a view of improving the community. The school community is consulted and their views taken seriously.

A number of challenges were identified; most of which stemmed from the fact that very little opportunities exist for the implementation of service-learning into programmes in higher education institutions. However, in spite of these challenges, I have attempted to demonstrate that opportunities do exist for incorporating service-learning into an existing module and programme.

Abstract: The study presented in this paper integrates a research project whose main goal is to explore new approaches to teacher education and professional development that emerge from the Web 2.0 paradigm. In this paper we present three different experiences on the use of social networks for the creation of a virtual community whose main goal is the professional development of teachers. The first experience is a Portuguese project named dajaneladomeujardim – (http://janelajardim.ning.com/). The second example is a north american project created and managed by Steve Hargadon and called Classroom 2.0 (http://www.classroom20.com/). The third project cames from Brasil and is called Eadamazon – Portal de EAD e e-learning da Amazónia (www.eadamazon.com). Lessons learned from the analysis of those projects will be presented and discussed.

Keywords: social network, technologies, Web 2.0, professional development.

INTRODUCTION

In the last few decades, the rise in digital technology influenced in such a significant manner the way people live and relate to each other, that knowing how to use and master those technologies is a sine qua non condition for any responsible citizen of the XXI century.

The advent of ICT's and the Internet favored great changes in educational paradigms, a new global network use philosophy being introduced, known as Web 2.0. This philosophy leads to new paths, diversifying the ways we communicate and interact in the network. In this context, many tools where developed with this goal, as in the case of social networks, which are increasingly used, and with more aims: communicate, relate, share, interact and… learn!

That being so, the Internet, as a connecting network, has become a society development factor, contributing to the rise in creativity, productivity, and to the creating of new knowledge. According to Fernandes & Araujo (online), the economical and socio-cultural ambient of the individual is marked and based mostly in the use of Information and Communication Technologies (ICT's), that, in a way, ensure the diffusion of new information distribution strategies, as the appearance of new communication models, generating a wide group of human behavioral and attitude change possibilities related to education processes.

At the speed in which these mutations occur, we felt the need to develop a reflection about the role these new technological environments may have in the education and formation of adults, more so on the training of teachers. In fact, teachers on duty today have at their disposal a growing offer in training opportunities that only demand having a computer with Internet access and a basic level of ICT knowledge. Accessing online training spaces allows the development of new competences and skills, needed by any XXI century citizen, who will no longer see school as the only space where learning occurs, but also in the new ways to communicate and the virtual communities themselves (Social Web), as alternative models to communicate, share and collaborative knowledge construction (Veen & Vrakking, 2009).

On the other hand, changing an educational system is a task that requires will, motivation and, most importantly, political will. In the European case, especially in Portugal, the Technological Plan – TP appears, as a way to coordinate the policies of the government, to make the economy more competitive, thru the stimulus of creation, diffusion, absorbance and use of knowledge, as an element of change, in order to consolidate Portugal in international and global economies.

The project of certification of Portuguese teachers in ICT competence may be considered one of the biggest challenges of the Technological Plan for education, being the cornerstone on the teacher training strategy, as it aims to improve and innovate pedagogical practices of teachers, using ICT's in their day-to-day classes (Costa et al., 2008). The program delivers, as structuring axes, content and training, as it considers that ICT competence development is directly linked to teaching-learning processes, also ensuring some flexibility,

that, in a way, takes in consideration the pedagogical contexts, and also the different levels of ICT competences the teachers already have.

Costa *et. al*. (2008:p.16), present three scenarios in respect to teacher's training in ICT's:

1. **"A" Scenario** – In respect to the TPE foreseen activities, each teacher gets involved in self and externally provided training;
2. **"B" Scenario** – The school's directive body, in conjunction with the Training Center, promotes a modular training program;
3. **"C" Scenario** – The teacher develops an autonomous training course, beyond the school offering.

Taking as reference the "C" scenario, that emphasizes and values the teacher initiative in individually developing his own training course, we realize that many initiative that explore the potential of social networks to create informal training spaces for teachers, that, by sharing and interacting with colleagues, promote self professional development and theirs, are already in action.

The present article has as main objective to show some on course experiences that display how social networks can function as informal spaces to professional development and to teacher training in ICT's. We believe that an analysis and reflection about these experiences may be an important step in grounding and justifying the project we are implementing in the state teachers network of Maranhão state, Brazil, which advocates the use of a social network as an online space, able to promote the professional training of teachers, and their capacities, in order to integrate ICT's in the curricula of Brazilian schools.

TEACHERS, TECHNOLOGIES AND TRAINING

Use of digital technologies is consolidating and assuming a prominent position, as necessary tool of the contemporary world, contributing to us being informed and in constant communication.

They assume a great importance role in getting all socioeconomic background persons together, allowing for the appearance of information exchange and knowledge sharing spaces. This becomes a challenge for schools, as teaching in the middle of the digital era contributes to create "never before seen opportunities to make teaching a motivating and passionate profession, which makes a difference to the future society. Such opportunities relate with new roles, new content and new methods of teaching and learning" (Veen & Vrakking, 2009, p. 14).

According to Ferreira (online), it is important to note that the use of technologies in a teaching context won't resolve all educational problems, but its use in a responsible way, with clearly defined objectives, is related with "the human and professional competence of the one who will intermediate the teaching and learning process: the teacher". So, that implies the construction of a new identity to the teacher, who, in face of technologies, must be prepared to act, in this new scenario: a teacher that can reframe learning and stimulate the collective production, in an autonomous and organized way, through digital networks.

According to Moura (2003), the scenario for change and teacher training must take into account the following criteria:

1. Take a position regarding information, selecting it;
2. Integrate diversified technological resources;
3. Adapt to the new characteristics of the school (active, participative and free);
4. Understand learning is not conclusive;
5. Comprehend school as a re-maker of critics.

These criteria may be considered as good practices that must be followed by all in the educational scene, both at national and international level. Because of this, the continuous training of teachers is a theme that assumes great relevance in public educational policies, that mobilize authorities to search alternatives and ways to qualify teachers that aim the concept improvement, the teaching and learning processes operationalization, since initial training only represents a phase, that anticipates the beginning of the teacher's professional actuation, them being – initial and continuous training - "nuclear components of professional development and curricular practices innovation" (Simão *et al*., 2009, p. 64)

These authors also emphasize that the European Commission has given special attention to teacher training as a way to fulfill the strategic objectives of the Education and Training for 2010, which aims to put Europe in the knowledge based economy route, making it more competitive in a global level (Antunes, 2007).

In this context, which is understandable, there are numerous efforts to consolidate a teacher training policy that must include a series of competences that not only take in to account the teaching methods, but which is also filled with training courses that allow the teachers to explore the opportunities delivered by

technologies, making them a resource to come up with individualized ways to learn, enabling the development of attitudes on investigation, deepening and reflection on developed work (Simão et. al., 2009)

The success of that training can only be exacted thru the commitment of educational managers and the school itself, in the sense of given the necessary conditions for its operation, searching responses to the problems felt in the school day-to-day, as with the need to get external support through interaction with other professionals, making teacher become active agents in their training process.

It is in this context that Costa *et. al.* (2008) underline that teacher training in ICT's will be more effective if it was given more training time followed by continuous accompaniment, thus reducing anxiety levels and teacher's fear of the new. To the authors, that accompaniment would be of great value, because, more than encouraging teachers, would make for experience changing moments, in the use of those technologies in an educational context.

So, what is expected from teacher training is, on a first level, that it tries to familiarize teachers with the technologies and, starting from there, a training program can be launched that can fulfill their necessities. Allied with the already mentioned factors, it is indispensable for "teachers can count on a support structure that is available at all times, beyond training sessions and formal moments" (Costa *et. al*., 2008, p.45). In a way, this contributes to ensure them because "the fact that they are more comfortable in the experiences they do with their students if they know they can have help when they need it" (idem).

We realize there is much to be done for ICT training to satisfy teacher's demands in the matter of disseminating a participating pedagogy, because, according to Ponte (2000, p. 67) "without a great dissemination of ICT in the places where people live and work, it will never be possible that these are used in a fluent and natural way. It's a resource managing and educational policy problem, where almost everything is to be done yet."

It is indispensable to make ICT a part of the teacher's life, aiming his involvement in "the student's learning, with the colleagues and other people of the society in general, so as to stop being the one that teaches, to become, mostly, the one that (co)learns and promotes learning" (Ponte, 2000, p. 89).

So, it would be interesting to create a space to live and share experiences, where teachers of the Portuguese speaking community could trade information, contributing to the construction of a training plan that goes in the direction of their wills and needs.

VIRTUAL SOCIAL NETWORKS

Virtual social networks have their concept based on participation and collaboration. Franco (2008), in his studies, says that networks are multiple paths, that have as a main characteristic the inexistence of a hierarchy, and that are constituted by various nodes or connections, favoring that communication flows in all directions.

Nowadays, networks have become keen environments to multiple informal learning, giving in, in some way, to the lifestyles of the people in this new model, that search the most diversified ways to communicate and share with a wide and culturally diversified universe.

Networks have taken a proportion never before seen, because some of them were conceived as relationship spaces, others as a way to store mp3 music, as a photo album. Orkut, MySpace and Facebook, as an example. But, with the passing of time, they assumed a quite different configuration from their main goal, incorporating some tools that contributed to increase interaction between people, as are forums, chats, news lists, among others. Ning, example giving, started as a Web services platform, but, more precisely in the beginning of 2007, it got a new configuration, allowing users to create their own personalized networks.

They reunite people interested in various themes. Some simply search for entertainment, other search for places to end doubts, share knowledge, others are moved by a common cause, and others search them to, through collaboration and interaction, build know-how and be the main character in their formative course.

This software allows people to group and organize around a defined theme, forming all kinds of community as: interests' community, interests' objectives oriented community, learning community and practice community (Henri & Pudelko, 2003).

Many professionals see them as a democratic space, and, because they are without a hierarchy, it seems to us that they create some kind of encouraging in participating and showing their anxieties.

SOCIAL NETWORKS FOR ICT TRAINING OF TEACHERS

As previously stated, networks can be a mean of expression and communication for professionals in any area. In education, they are becoming accepted by a major group of teachers' communities. Surely, there are those resistant to change, who prefer the "traditional" way to communicate and build knowledge.

But this reality has become modified. There are a lot of teachers that search for them to enhance knowledge and, mostly, to acquire competences in digital literacy.

And it is on this aspect that we present some networks, namely: dajaneladomeujardim, classroom2.0 and eadamazônia.

"dajaneladomeujardim"social network (http://janelajardim.ning.com/), was conceived in the Ning tool, it is active since October 2007 and has 612 members. This network is a part in a doctorate investigation from University of Minho – Braga – Portugal, and has the objective of providing a space to show the work of the children in kindergarten, share knowledge, mainly with teachers and others interested in the field. More than that, it has the objective of allowing the professional development for teachers in this level of schooling. (see image 1)

Image 1: Layout for the "da janela do meu jardim" webpage

Presently, the network shows 63 discussion topics in the forum, ranging themes related to child education methodologies referring all knowledge area, and also digital technologies, which constitutes, in our opinion, a plus, because it can contribute to digital inclusion and literacy development in the network members.

It also has 75 links to other sites. Something we feel is extremely important is the way it got the parents involved, by offering them a space so they could post the activities they develop. That space goes from a home meal recipe blog to those that discuss security of children in the Internet. Beyond that, it also has a space named "window to grow reading" with 6 links to other sites, and 74 videos.

We can say it is a network which is growing exponentially and that it gains more users every day. We say this based in statistical data provided by an application used by the network creator called RevolverMap, which showed us, in the day of our research, that the network, by that time, had 3070 visitors.

"Classroom 2.0" social network (http://www.classroom20.com) created by Steve Hargadon in the United States. Presently with 51.203 members, it's a network meant for people interested in the Web 2.0 tool that have as an objective to share and build knowledge in the technologies area. According with the author of the network, it's a space meant for educators to have the opportunity of being part of a digital dialogue, in order for them to acquire competences and skills in the handling of Web 2.0 tools and in that way have a personalized learning.

It's quite a big network, with 596 discussion groups, 7.314 forum topics, that also offers a language filter, which leads us to believe it's the most advanced model from Ning, "Ning Pro".

Image 2: "Classroom 2.0" social network webpage layout

The main page presents a profusion of links that point to other sites that work directly with other tools applied in an educational context, which can be searched by tool type, by subject or also by tags.

According to information collected in the environment itself, the network was nominated for three Edublog 2010 awards: "Best Educational Webinar Series", "Best Educational Use of a Social Network", and "Best Use of a PLN". That shows that the network is really being effective and, most importantly, is being recognized as a multiple-learning providing environment.

With all the tools available, we believe that this social network could be helpful in aiding teachers find new ways to integrate digital technologies and, in that way, develop more innovative classes, approaching school and the world as experienced by young people, which is filled with technological resources.

Eadamazon – Amazonia portal for OSL and e-learning (http://www.eadamazon.com). This portal is meant to divulge Amazonia's Of Site Learning and e-learning initiatives. From observation and analysis of the portal we realize that, more than courses, tutorials, videos, lectures, e-books, job announces and links to other sites connected with the theme, it is a space where people who take an interest on the matter can interact, sharing their professional and personal experiences.

Based on the studies of Grande (2003, p.19), and from the contents and proposal that it shows, it seems to us that it is a "vertical" portal, since it is specialized on only one theme, responding to the interests of a specific group.

Image 3: Eadamazon social network webpage layout

We can also classify it as an educational portal, since it presents communication tools that enable cooperative learning between its members, significantly contributing for the teacher to draw its own formative journey.

CONCLUSION

The social network concept has today a new meaning, since the appearing of the Internet and, mostly, since the Web 2.0 applications generation. When we talk, today, of social network, we think of relationship sites, that are not well regarded by parents or teachers that, thus, ignore many of the educational potential of these environments.

This is an additional reason to show how social networks can be spaces where knowledge is built by sharing and interaction between its members. In the three examples given, the social software was used constructively and in a teacher's professional development logic; in the first case, parents participation was always encouraged and that was, without a doubt, one of the factors to justify the success that the experience keeps through the almost three years it is working. The presented examples show that many teachers, citizens of the XXI century, seek informal spaces for their professional development that transcend the walls of their school, community or geographical region; that, in those environments, they can personalize their formative journey according with their time and professional interests; that there are strategies that assure the permanence of the virtual community members, even if they know they are not getting any type of certification for the training they receive.

We believe that social networks can be an enabling space to the sharing of multiple educational experiences and a space that favors the interaction between teachers that can, that way, learn from one another. Being part and communicating in these spaces can be an additional enhancer so digital technologies become part of the teacher's day-to-day in the classroom.

The teacher's participation on collaborative social networks may help the professional on identifying the weak and strong spots of his practice, develop a taste for learning how to learn, as well as sharing knowledge and contribute with learning to the whole community, in a communal constructivism perspective as recommended by Holmes *et. al*. (2001).

85 - Teacher Professionality and Professional Development in Communities of Practice – The Case of Collaborative Groups

Vanessa Moreira Crecci[1] and Dario Fiorentin[2]

Department of Teaching and Cultural Practices, Faculty of Education (FE), State University of Campinas (Unicamp), Brazil
[1]vancrecci@gmail.com, [2]dariof@unicamp.br

Abstract: When analyzing the constitution of teacher professionality in the interior of a collaborative group of reflection and study about its teaching and learning practices in basic school, Fiorentini (2009; 2010) found among the participant teachers a singular way of being in the profession and qualified it as being interactive, reflective and investigative. The emergency of this type of teacher professionality instigated us to investigate how the same is constituted in these *communities of practice* and how its participants develop professionally. In this paper we present and we argue some theoretical conceptions that serve as the framework for this research project such as: teacher education in communities of practice; teacher professionality, professional development and collaborative groups. The methodological procedures of the research are also presented, underlining the processes of gathering and analysis of data.

Keywords: Communities of Practice, Teacher Professionality, Professional Development, Mathematics Teachers

INTRODUCTION

Researches and discussions about teacher education have undergone great advances in the three last decades. Currently, different conceptions of teacher learning coexist, including varied images: of knowledge; of professional practice; of the relations between knowledge and practice; of the social, intellectual and organizational contexts where the learning of the teachers takes place; and of the way in which this learning connects with the educational change and the intentions of the school (Cochran-Smith & Lytle, 1999).

Fiorentini (2008, p. 59-60), based on António Nóvoa, points two basic models of teacher education: *structural* and *constructive*. In the structural model, the teacher education is structured from the perspective of the rationality technique or of kind of top-down, in which the education is organized from a model that assume the previous appropriation of knowledge, generally distanced of the practices of the teachers, to be later applied in the school practice. Even in the case of continued education, in this model, a previous update of the knowledge considered basic for the exercise of teaching is foreseen, without the demands of the teachers and the challenges or problems of its field of work being taken into consideration.

On the other hand, the constructive model of teacher education estimates the existence of a continuous process of interactive and contextualized reflection about the pedagogical and teaching practices, articulating the educational and professional practices. This implies a relation of partnership between the educator and its students, that can collaboratively act in the search of understanding of the problems and challenges of the teacher work in the current context, and can also act in the construction of alternatives of intervention in the school practice. It is common, in this context, the formation study groups and research-action, which analyze the practices that are in effect and innovative, elaborate together projects of intervention in the practice, followed by moments of registering/documentation of the educative activities and of reflection/systematic analysis of the same ones. That is, in the *constructive* model, the starting and finishing points of teacher education are the practices and the knowledge brought, produced and mobilized by the teachers in different contexts of school practices.

From the 90's, guided by this constructive conception of teacher education and from the initiative of university professors/researchers, and later from the initiative of the school teachers, appeared in Brazil collaborative groups of work and teacher education that are dedicated to the study of the ways of teaching and learning mathematics in the schools. We can consider that such groups constitute *communities of practice* (Lave & Wenger, 1991) or local *investigative communities* (Cochran-Smith & Lytle, 1999) formed by school teachers, university professors/researchers and/or future teachers who study, share, argue, investigate and write about the pedagogical practice in mathematics on the schools in a collaborative environment. These communities, according to Fiorentini (2010, P. 577) have constituted themselves in a

"alternative for the professional development of teachers and the production of a repertoire of professional knowledge based on inquiries about the practice of teaching and learning mathematics".

From this context, we formulate the present research project with the objective of describing and analyzing the process of constitution of the teacher professionality and the professional development of teachers who teach mathematics and who participate in collaborative groups of reflection or of inquiry about their professional practices.

In the following segment we present and discuss some theoretical conceptions that serve as framework to this research project and that are related to teacher education in communities of practice; to the constitution of the teacher professionality; and to the professional development of teachers who participate in collaborative groups of reflection and investigation on practices of teaching and learning mathematics in basic school. The methodological procedures of the research are also presented, underlining the processes of gathering and analysis of data.

TEACHER EDUCATION IN COMMUNITIES OF PRACTICE

In the last decades, one of the biggest concerns related to the politics, to the research and the debates centered in education has been teacher education. On this thematic, we find the defense of many different ways of carrying through this practice, amongst which there is the education of teachers in *communities of practice*. In these communities, it is recognized that the teachers constitute some ways of being in the profession, that is, constitute their teacher professionality and develop professionally.

In recent years, authors as Gama (2007), Nóvoa (2007, 2009), Fiorentini (2009) and Imbernón (2009) have appropriated the concept of *community of practice* (CoP) to investigate the education of teachers.

According to Imbernón (2009, pp. 79-88), a *community of practice* of permanent teacher education would be a group of teachers who interchange, reflect and learn mutually about their practice. The community would start to be formative when it's allowed to the teachers the elaboration of a culture that is proper to the group and not only the standardized reproduction of the dominant social or academic culture.

Nóvoa (2009, p. 21), based on Pat Hutchings and Mary Taylor Huber (2008), points out the necessity of strengthening the *communities of practice* of teacher education that must consist in a space formed by educators compromised with research and innovation, in which ideas about teaching and learning are discussed and common perspectives about the challenges of the education of the students are elaborated.

According to Fiorentini (2009, p. 237), the expression *community of practice* was introduced by Lave and Wenger (1991) to assign the social practice of a collective of people who participate of "a system of activities in which they share understanding about what they make and what this means in their lives".

Wenger (2001, pp. 99 - 114) points that a CoP has three basic characteristics: *the mutual commitment*, a *joint practice and the common interest*. Fiorentini (2009) identified of the following way these characteristics in a collaborative group of teachers who teach mathematics that he investigated. The *mutual commitment* inhabits in the participation in the *joint practices* of reflection and inquiry about the *practice of teaching and learning mathematics in the schools* (common interest). According to Fiorentini (2010, p. 581), the *participation*, in the perspective of Wenger (2001), understands the process in which the subjects of a community share, discuss and negotiate meanings about what they make, speak, feel, think and produce together. In this way, to participate in a CoP means to engage in the activity of the community as operating and productive member. This implies to appropriate of the practice, of the knowledges and of the values of the group.

Gama (2007), when analyzing the professional development of teachers in the beginning of their careers who had participated of collaborative groups, underlined that the developed learnings are associated directly to the collective dimension of the group, therefore the collaborative groups can be considered small communities constituted by engaged people, in which a type of learning occurs characterized by Wenger (2001) as *social learning*.

Fiorentini (2009) interprets *social learning* as a social phenomenon loaded by ideologies and values and that it emerges of direct participation in social practice, independent of being organized with the intention to teach something to somebody. About the knowledges and the participation in a CoP, Fiorentini underlines that "the knowledges of a CoP, therefore, are expressed through the shared forms of doing and understanding inside the community, which results in dynamics of negotiation involving active participation and reification of the practice". Still, according to the author:

Reification, for Wenger (2001), means "to become in something". However, this does not mean that "something" is necessarily concrete or material. The reification, for example, can also be a concept, that is, something abstract; it refers to the process of giving shape and meaning to the human experience from the production of objects such as artifacts, ideas, concepts or written texts (Fiorentini, 2010 p. 571).

In this direction, the reifications of the collaborative groups can be perceived and be conferred in the written practices, as well as, in the collective moments of production and negotiation of meanings about the practice of learning and teaching mathematics in the schools.

TEACHER PROFESSIONALITY AND PROFESSIONAL LEARNING

When discussing the specifities of the teaching work, Gimeno Sacristán (1991), searches for support in the professionality concept, which is understood by him as "(...) the affirmation of what is specific in the teaching action, that is, the set of behaviors, knowledges, dexterities, attitudes and values that constitute the specifities of being a teacher" (p. 65).

Contreras (2002, p. 74), based on Gimeno Sacristán and Hoyle, relates the professionality "to the qualities of the professional practice of the teacher in function of what the educative work requires". And clarifies that it is not only about the description of the performance of the work that is to teach, but also of the values and the pretensions that are intended to be reached in the context of the profession.

Fiorentini (2005), based on Fullan and Hargreaves, conceives teacher professionality as a way to produce and to project the work and the profession, that express a quality, in view of the social and politic demands of the students and the political commitment of the teacher. This professionality, however, is constituted in the social interactions of the teachers, that is, it is constructed by means of participation of the teachers in different communities, especially in those that focus on the professional development of the teachers, as it is the case of the collaborative groups.

In this direction, and considering the different meanings of professionality in the literature, Fiorentini (2009, p. 250) distinguishes at least two different meanings of teacher professionality: one in the perspective of the neoliberal educational politics marked by the discourse of the abilities and the logic of the qualification; another one, that defends the construction of a "interactive and deliberative professionality", that attributes to the teachers: autonomy; plurality of knowledges; capacity to analyze and to evaluate, in a critical community, its work, deliberating on the routes of its practice and the values to be cultivated.

Concerning the concept of professional development, Rocha and Fiorentini (2006, p.3) represent a new perspective of conceiving the teachers as an independent and responsible professional who produces knowledge from its practice. In this perspective, the professional development of the teacher can be conceived as a dynamic, continuous process and never-ending. The authors clarify, still, that they understand the education and the professional development of the teachers "as a continuous process that starts before entering college, is extended throughout all the professional life and happens in the multiple spaces and moments of each one's life, involving personal, familiar, institutional and sociocultural aspects" (p. 4-5).

Close to this perspective, Day (1999, p. 20-21) conceives professional development as a result of all the spontaneous experiences of learning and activities conscientiously designed, carried through for the benefit, direct or indirect, of the individual, the group or the school and that contribute for the quality of education in the classroom.

It is from this conception of professional development of the teachers that we intend, in the present inquiry, to understand how the teachers learn professionally and constitute their professionality in the context of the collaborative groups.

THE CONSTITUTION OF TEACHER PROFESSIONALITY AND THE PROFESSIONAL LEARNING IN COLLABORATIVE GROUPS

When analyzing the constitution of teacher professionality in the interior of a collaborative group (called Saturday Group), Fiorentini (2009, p. 251) underlines that there are evidences of the constitution of a way of being in the profession that is characterized as interactive, reflective and investigative. According to the author, the collaborative practices involving school teachers and university educators, or professionals and researchers, emerge as the possibility of the collective construction of a interactive teacher professionality that is renewed permanently.

In these collaborative groups, the teachers constitute their teacher professionality by discussing, analyzing, reflecting, investigating and sharing the underlying questions to the exercise of the teaching profession, having teacher educators and academics of the university as critical partners.

On the organization of the dynamic of these collaborative groups and their relation with professional learning, Gama (2007, p. 144) points that, in his research with collaborative groups, it was possible to identify some practices and/or dynamic that act as catalysers of the professional learning of the participants: coordination and register of the presential meetings in a shared and alternated way; theoretical and methodological studies defined from the demands of the participants; sharing of written and verbal narratives; joint construction of pedagogical materials; publications of papers and books with the

participation of the group; use of virtual space for doubts, exchange of information and socialization of theoretical and pedagogical materials. In the groups that Gama (idem) studied, the meetings are coordinated and described - through documents entitled memories or acts – using a rotation system by the different members of the groups.

On the professional learning of teachers that are in the beginning of their careers and that participate in collaborative groups, Gama and Fiorentini (2008) underline that:

> (...) in the collaborative groups, the look of the other aids in the promotion of questionings and distancing of the practice of the person who tells the group its stories or experiences in the classroom. It also helps to produce new meanings and to evaluate the experience of each other, allowing, thus, the professional development and the constitution of professional identities of the participants (p. 10).

METHODOLOGICAL PROCEDURES ABOUT DATA GATHERING AND ANALYSIS

The data for the development of the research will be collected in a first phase through a questionnaire with open and closed questions to be answered by teachers who teach mathematics and that participate in collaborative groups. In this phase, we intend to identify and to describe the following aspects: which are the contributions of the group for its professional development and teacher education; which are the contributions of the group for the confrontation of the challenges presented by the teaching practice; how the teachers contribute with the development of the group that they participate and which are possibilities or limitations of the collaborative group for the improvement of the teaching practice. The questionnaires will be distributed by the researcher to the teachers who teach mathematics that participate in Brazilian collaborative groups, using electronic means (email), postal (post office) or presential. Considering that, although questionnaires have a low usage frequency in qualitative research, they can serve as a complementary source of information, specially in the initial and exploratory phase of the research (Fiorentini & Lorenzato, 2006, p.117).

In the second phase, aiming at a deeper and qualified investigation of the process of professional development, of teacher learning and of the constitution of professionality, a sample of three to four teachers that participate in collaborative groups will be selected, and these teachers will be submitted to semi structuralized interviews that will be transcribed for analysis. This modality of research, according to Fiorentini and Lorenzato (2006, p.121), is commonly used by the educational researches, being that the researcher, intending to deepen himself on a phenomenon or specific question, organizes a script of points to be contemplated during the interview that can in modified in accordance with the development of the interview. The transcription of these interviews will be a part of the corpus, as well as written publications of these groups and the papers and/or didactic materials produced by the selected teachers, such as: texts, ideas, strategies, didactical materials, digital medias, manifests, etc.

In the third and last phase of the field work, some observations will be done, with notations in a field diary, of the meetings of collaborative groups where the interviewed teachers participate. This material will serve for the composition of the analysis and the description of the dynamics of the collaborative groups where the teachers - subjects of the second phase - participate.

The data will be analyzed in a qualitative way, considering that this way of doing research "tries to portray the reality in the deepest and more complex way possible, emphasizing the interpretation or the analysis of the object in the context where it inhabits" (Fiorentini & Lorenzato, 2006, p. 110).

In this direction we take as base the authors Lüdke and André (1986) that underline the basic characteristics of this way of research and point that it has the natural environment as its direct source of data and the researcher as its main instrument. According to the authors, the gathered data are predominantly descriptive, and the concern with the process is bigger than with the product and the meaning that people give to things and to their life are the focus of special attention for the researcher. The data analysis tends to follow an inductive process.

In relation to the this project, the analysis and the interpretation of the content of the discursive informations will be developed by means of a process of *mix categorization*, because we intend to get "the categories from a confrontation between what the literature says and what the field registers show" (Fiorentini & Lorezato, 2007, p. 135). In this way, we intend to triangulate some instruments of research to compose the corpus of analysis, in a way to guarantee a better understanding and approximation of the processes of professional development and constitution of the teacher professionality of the subjects that participate of collaborative groups.

SOME FINAL CONSIDERATIONS

Being a project in implementation phase, we are open to critics and contributions to its development. We intend, beyond what we already announce previously, to describe the work dynamics of the groups in which the selected teachers are part of in the second phase of the field research; to describe the process of professional learning of the participants from their participation in the group and to characterize and analyze the type of teacher professionality that is being constituted by them. We also intend to describe, to detail and to analyze the reifications produced by the selected teachers and their contributions for the teachers' professional learning and improvement of teaching and learning mathematics practices in schools, as well as, the personal and professional development of their colleagues and of the restricted teaching community (collaborative group or school) or broader (the community of mathematics teachers that act in the schools and the community of teacher educators that act in the universities or centers of teaching education), as well as the public politics of education. For this, we will take as reference, the publication of written works of the teacher, produced videos or didactic materials, their participation in congresses or in the management of agencies or public services (participation in projects of continued education, lectures, and administrative positions in education secretariats).

We consider that the theoretical framework of this study must be extended and be confronted with other conceptions of formation in communities and professional learning, such as the studies and works of Cochran-Smith & Lytle (1999), Jaworski (2008), Fiorentini (2010) and Hargreaves (2004; 2007).

Finally, we underline the context in which this research is developing. Although the research had evidenced the contributions of the collaborative groups for the professional development of teachers and for the improvement of their teaching practice, the public politics have yet to recognized and validate these spaces of work and education. Rarely, these teachers receive aid and validation for the hours of work and study in these *communities of practice*. We agree with Freitas (2007, p.1207) when defending that the politics of teacher education should take in consideration the results of the studies of the researchers who have guided and collaborated with the educators, their movements and entities in the debate about the principles and the framework of education. In Brazil, the politics of teacher education, especially those of the State of São Paulo, still insist on promoting a neoliberal politics of teacher education, as they prefer to invest on a large scale in the (des)continuous education of teachers and in the external control of the teaching work, through evaluations that take in consideration only the curriculum proposed and elaborated by specialists and without the participation of the teachers who act in the schools (Fiorentini, 2008).

elmano@iseg.utl.pt

Abstract: The explosion of mobile technology use within the general population means today's students are often referred to as Digital Natives or the Net Generation (Oblinger & Oblinger, 2005; Prensky, 2001,). Baston (2008) notes that our educational systems are not yet fully recognising the changes which have arisen from this generation - therefore, we should be seeking ways in to embrace social media for the purposes of academic adjustment? By examining extant literature complemented by primary data, two European Institutions (ISEG, Lisbon, Portugal and Northumbria University, Newcastle upon Tyne, UK) have designed models which utilise technology to engage students in support related activity. One such model, using the social networking package *'Facebook'* has been piloted at Northumbria University. This paper evaluates this model and contemplates how social networking could be successfully integrated into future student support and learning mechanisms.

Keywords: social networking, student retention, mentoring, student adjustment.

INTRODUCTION

It is well recognized that students will require a period of adjustment when entering Higher Education (HE) (Dyson & Renk, 2006). Vincent Tinto (1975) was one of the first researchers to recognize how the adjustment process can affect whether or not a student remains beyond their first year of study. Retention, as a topic, continues to have prominence due to its link with widening participation, which has increased from 15% in the late 1980's to 35% in 2000 (Chowdry *et al.,* 2010).

Peer mentoring is one popular form of intervention which is designed to assist in the academic adjustment process (Crisp & Cruz, 2009). The majority of schemes are based on face to face contact once students have entered University (Clark, Andrews and Ingelby, 2010). Peer mentoring in a virtual form is rare and evaluation of any virtual scheme does not yet appear to feature within peer mentoring or academic adjustment literature.

This paper begins to readdress this: firstly by summarizing a scoping study which explored which technology was the more likely to promote and sustain student engagement in a peer mentoring context; secondly, a pilot utilizing the favoured technology is evaluated using mixed methodologies whilst following action research principles.

ACADEMIC ADJUSTMENT

Students' adjustment to HE is one of the more prominent areas of pedagogic research. The most significant authors in this area being Vincent Tinto (1975). Mayhew, Vanderlinden and Kim (2010) recognize that these programmes for improving retention are open to criticism as evaluation rarely makes a direct link to student learning. This is often due to the concentration of many induction (or orientation programmes) focusing on the social dimensions of the adjustment process. This is understandable as Christie *et al*. (2008, p. 567) states *"becoming a university student is an intrinsically emotional process"* and as cited by Dyson and Renk (2006, p. 1232) *"all new students go through an adjustment phase upon entry to a university with each student varied in his or her own pace of development."*

The one factor consistently noted within retention research is the crucial six week period at the start of University where students often decide whether or not to continue studying at an institution (see for example, Heirdsfield, Walker & Walsh, 2008 and Perry *et al.* 2001). As stated by Christie *et al*. (2008) and Stratton *et al*. (2007), amongst others, the adjustment process involves a variety of complex factors. Peel (2000) summarises that there is often a paradox of the part of this adjustment process in that what students often look forward to, independence and freedom, can also be a significant source of anxiety. Empirical data from

a number of studies also indicates there are some factors which can be significant. Students are more likely to withdraw if:

- A student is the first generation in their family to enter HE (Ishitani, 2006);
- Cultural values of international students are not valued by home students (Zepke & Leach, 2005);
- There is no orientation to a campus (Christie *et al*., 2008);
- There is a lack of personal relationships with staff (Peel, 2000);
- The course does not meet expectations (Pendleton, 2005).

Studies generally point to University as being a potential lonely experience and therefore as stated by Christie *et al*. (2008) university cultures need to adapt and become accountable for the adjustment process.

Peer mentoring

Peer mentoring is one well established method employed by HE institutions to assist in the integration of students into university. The topic attracts a profusion of research which is reviewed on a regular basis, most recently, by Crisp and Cruz (2009) and Terrion and Leonard (2007).

The concept of mentoring arose from the work of (Kram, 1983) who looked at the effects of relationships within the workplace. Terrion and Leonard (2007, p. 150) base their own definition of mentoring on this original work:

> *"Peer mentoring is a helping relationship in which two individuals of similar age and/or experience come together, either informally or through formal mentoring schemes, in the pursuit of fulfilling some combination of functions that are career-related (e.g. information sharing, career strategizing) and psychosocial (e.g. confirmation, emotional support, personal feedback, friendship)."*

Peer mentoring has been proven to increase student retention (see for example Boud, Cohen, & Sampson (2003) and Muldoon (2008)), as well as generally improving the first year experience of students (see for example, Farrell *et al.* (2004) and Mee-Lee and Bush (2003)).

The majority of UK peer mentoring schemes work on a face to face basis once students enter university (Clark *et al*., 2010). However, the 21st Century has brought about a change in the way literature describes the typical student age group. Commonly students joining HE now were born in the 1980s or 1990s. Technology is seen now as being an integral part of everyday life and as such these students are increasingly viewed as the Net Generation or Digital Natives (Oblinger & Oblinger, 2005; Prensky, 2001). A number of commentators suggest that this essentially requires educators to make a radical shift in their own use of technology. Baston (2008), for example, notes how learning has shifted from the desktop to the internet with Web 2.0 technologies being more in line with the reality of learning than the book. DeGennaro (2008) points out that educators now need to craft learning design around the technologies which are important to them. This would suggest peer mentoring is one way in which technology should now be incorporated - a point picked up by some peer mentoring commentators. Ensher, Heun, and Blanchard, (2003) believes there are a number of advantages to on-line mentoring such as reduced costs, a counteraction of demographic and geographic issues, greater mentor access and ability to immediately record of interactions. Whilst, Hwang (2004) notes that virtual forms of communication could increase the positive learning benefits which are gained from student networking across all cultures.

In a recent UK report, Clark *et al*. (2010) found that over 80 UK institutions operate some form of peer mentoring. The content analysis conducted indicated that virtual based schemes are a rarity. Only nine institutions appeared to be using some form of virtual support, the majority of which supplemented face to face sessions by email contact. There is some exploration of how technology can provide support, two notable examples are: (1) Glasgow Caledonia University - their initiative on Emergent Technologies for Learning (Anon, 2009) includes a project which explores how the virtual world Second Life can help students become more effective learners. This incorporates an i-CAMPUSS (Internet College Articulation and Mentoring Project for Prospective University Students) initiative where student mentors use Second Life to interact with first year (and even prospective) students to explain things about schools and services that new students need to know; (2) Madge *et al*. (2009) explores social networking for supporting learning and observed how pre-registration engagement with the social networking site *'Facebook'* influences students' post-registration social networks. Students reported joining *'Facebook'* as a means of making new friends at university, as well as keeping in touch with friends and family at home. It was noted that *'Facebook'* formed

part of the 'social glue' that helped students settle into university life. Northumbria University was also interested in exploring how technology could be used in a mentoring context. Three forms of technology were initially considered:

- Virtual Learning Environments (VLE) - an integrated set of tools such as folders, email, quizzes and discussion boards to support learning (Svane & Smedley 2004);
- Social Networking – spaces for personal profiles which can be publically shared (Boyd, 2008);
- Virtual worlds – an example of which is Second life which enables the creation of characters that interact in reality or fantasy based environments.

These technological models were assessed using two methods - a desk-based review of the relevant literature complemented by a traditional survey approach. Selection was based on the following criteria highlighted as facilitating academic adjustment:

- Would the technology allow contact to be made with the students pre induction?
- What technological skills would be required on the part of:
    o A student mentor and/or academic staff;
    o A 'joining' student?
- How established is the use of the technology within HE?
- Is the technology suitable for initiating peer interaction?
- What is the current usage, across all demographic factors, of these technologies amongst the incoming student population?

Table 1: summarises the three models considered against the above criteria, detail of which is reported in a separate article (Smailes & Gannon-Leary, 2011)

Criteria	Virtual Learning Environment	Social Networking	Virtual worlds
Pre -induction	No, access only available after enrolment.	Yes, public access.	Yes, public access.
Skills required Mentor/Staff	Basic skills set required (Gannon-Leary & Turnock, 2007).	Basic skills set required (Boyd, 2008; Tufekci, 2008).	Advanced skills set required. (Browne *et al.*, 2008).
New student	Would require initial training but can operate with basic skills set (ibid).	Basic skills set required (ibid).	Advanced skills set required (Wetsch, 2008).
Current use in HE	Well established (MacLaren, 2004).	At the early stages of adoption (Liccardi *et al.*, 2007).	Increased interest in use (Kirriemuir, 2008; Peachy, 2007).
Facilitates peer interaction	Sole and Lindquist (2001) note the potential for peer interaction. Students are unenthusiastic about VLEs (Conole & De Laat, 2006).	Potential for creating social learning environments that offer 'social communities of practice' (Cain, 2008; Ryberg & Christiansen, 2008). Social networking engagement is culturally dependent (Boyd & Ellison, 2007)	Community based environment that mirrors reality (Kirriemuir, 2008).
Current usage amongst all demographic groups. (Source: Northumbria Survey).	Two-thirds of students used daily further 30% weekly across all demographic factors.	Vast majority of group use daily no cultural difference found.	Negligible usage amongst student cohort, majority not heard of most well known virtual world Second Life.

The evidence indicated that a model involving social networking sites had the greatest potential for supporting academic adjustment through peer mentoring. This was primarily due to its immense popularity

714

amongst the student body alongside the ability for the academic adjustment process through mentoring to occur before formal student induction.

SOCIAL NETWORKING FOR SUPPORTING ACADEMIC ADJUSTMENT

Understood to have begun in the mid 1990s, there are copious numbers of social networking sites worldwide, the more populous sites began to emerge from the early 2000's (Boyd & Ellison, 2008). Ronn (2007) notes how social networking sites are the reported to be the most visited pages apart from search engines. Social networking sites are defined as differing from other forms of computer mediated communication due to three notably public features i.e. a personal profile, links to friends and open comments on those profiles (Boyd & Ellison, 2008). Social networking is now a global phenomenon, as noted by Tufekci (2008) a number of studies illustrate that students consider themselves to be heavy users of social networking sites. Boyd (2008, p. 136) comments on how social networking provides an environment for young people to formulate their identity within public forum and the emergence of such sites has provided a *"whole new social realm for youth"*. A number of researchers are now recognizing the increasing potential of social networking in student learning. Huijser (2008) observes how there seems to be a desire from the students themselves for what students regard as their "living technologies" to be used within learning. Berg, Berquam, and Christoph, (2007) suggest universities should be looking at the ways in which social networking can be used in a positive way with students in order for them to see benefit of student: staff communication in a space students think of as their domain. Cain (2008) recognizes the role of social networking as an aid in helping students feel that they belong and hence could aid retention.

Although there is abundant variety of social networking sites, one site dominates in the UK, US and much of Europe above all other namely *'Facebook'* (BBC, 2010 using Nielsen 2010 as a source). '*Facebook*'s' popularity extends to Northumbria's student group. In a survey conducted in 2008 (n=451), 75% of students from all demographic groups stated they used *'Facebook'* on a daily basis, opposed to the next most popular site MySpace used by only 5% of the sample (Smailes & Gannon-Leary, 2011). Boyd and Ellison (2008) note that social networking is culturally dependent. However, Northumbria's primary data showed that although international students used alternative sites, they were used less frequently and alongside *'Facebook'*.

The ISEG *'Facebook'* page[109] is a very active social network, created on July 2010, it has currently about 4200 'friends': students (current and potential; Portuguese and international), teachers and alumni. Its contents include: promotion of all ISEG courses; dissemination of events (e.g. academic, cultural, company presentations, job fairs); information to secondary schools; relevant scientific activities including projects, awards and research papers. It is also a space for discussion and resolution of issues inherent to academic life at ISEG, both in terms of logistics and in terms of academic issues. The discussions and questions are monitored by a team belonging to ISEG Human Resources staff and the questions are answered online at any time. The most popular topics are Information, Notes, Fora and Photos.

Despite its popularity, social networking and its use within education continues to court controversy (Selwyn, 2009). Goodall (2008) notes that despite being comfortable with the technology students are likely to need advice on its appropriate use. A similar point is picked up by a number of authors who consider the negative implications which may arise from the public nature of the sites, these range from personal safety, employment prospects and bringing an institution's reputation into disrepute (Gross & Acquisti, 2005; Kolek and Saunders, 2008; Lenhart *et al.,* 2007; Peluchette, 2010). However, Huijser (2008) believes there is perceived threat of using social networking in learning as it is likely to be due to the lack of control on the part of the educationalist.

Notwithstanding these concerns, on the whole, the evidence led the authors to believe that a model involving '*Facebook*' had the greatest potential for supporting the academic adjustment of students. However, in line with any mentoring programme, mentor training is essential therefore it was imperative in creating a virtual peer mentoring model to include a consideration of how this instruction was designed to include guidelines on how '*Facebook*' could be used in a secure and professional manner (Terrion & Leonard, 2007).

PILOT EVALUATION

The pilot virtual mentoring model involved a small cohort - BA (Hons) Marketing Management at Northumbria University. A mentor was recruited in May 2010 and alongside the principal researcher created materials for August 2010 when the site was launched. In order to host resources, a *'Facebook'* group

---

[109] http://www.facebook.com/pages/ISEG-Instituto-Superior-de-Economia-e-Gest%C3%A3o/141467479212632#!/pages/ISEG-Superior-de-Economia-e-Gest%C3%A3o/141467479212632?sk=wall&filter=1

account was created. A *'Facebook'* group was felt to be appropriate due to its advanced security features and the availability of additional features not present on a personal account (e.g. discussion board). These resources included:

- Guide to the campus, including internal room layouts. Information which (Christie *et al*., 2008) believes should not be under estimated in its importance for academic adjustment;
- Photographs of students from Year 2 including quotes passing on advice;
- A guide the academic referencing style use at Northumbria;
- Details of the 'Ask Liz' service. A one stop shop which (Mayhew *et al*., 2010) found to be factor common to successful orientation programmes;
- A guide to interpreting the timetable;
- Details of the Students' Union activities in the Welcome week.

As part of the University acceptance processes, students were sent details of the '*Facebook*' group in the joining instructions. At this stage the researcher began to undertake regular observation of activity in the groups. A similar technique to that used by (Selwyn, 2009) citing (Davies & Merchant, 2007) whom believe as both an observer and an analyst this is viewed as non-participant ethnographic research.

Within days of these letters being distributed, the majority of new students (85%) had joined the *'Facebook'* group. Observations of wall activity showed that the students quickly became *'Facebook'* friends with each other - although, international students were found to have fewer friends. In the following few days, the mentor also received questions from students, the replies to which were posted publically either onto the wall or a discussion page. Examples of queries related to issues such as the number of hours they would be expected to attend and reading lists for the programme's modules.

To assess whether this supporting material had been useful, a traditional survey approach was used. The survey questions gathered both factual information (e.g. resources used, frequency of access) and opinion in the form of Likert statements. These statements were an amalgamation of proven questionnaires designed to measure factors such as commitment to the organization, relationships with peers and mentors, plus persistence towards learning (Cole, Field, & Harris, 2004; Sanchez, Bauer, & Paronto, 2006). Although the cohort was small (n=20) a 100% response rate was achieved.

Demographic analysis revealed that the majority of the group originated from the UK. There were four international students in the cohort, 3 originating from China, one student from the Middle East. More than 50% of the students noted that they were the first generation in their family to attend university - a group known to be more likely to leave HE (Ishitani, 2006).

The vast majority of the cohort (80%) used *'Facebook'* on at least a daily basis. However, cultural differences in use were now more pronounced. In 2009, China banned *'Facebook'*. Although, the students from China had *'Facebook'* accounts, these were used less frequently, had far fewer friends (both from the cohort and in general) registered on the account. *'QQ'* is now the most prevalently used site in China (BBC, 2011) and this was also clearly the more popular and frequently used site for the Students from China – a significant shift from the empirical data collated as part of the scoping study (Smailes and Gannon-Leary, 2011).

All but one, an international student, said that they had visited the *'Facebook'* Group at least a few times although most said that the last time the site had been accessed was within the first couple of weeks of the first semester. Notably, two of the international students reported they had accessed the site recently which may illustrate the additional stress (e.g. 'cultural shock') international students experience (Baron & Carr, 2007). The researchers were aware that students needed to consciously log on to the group to access the information therefore, one line of enquiry was whether a direct newsfeed link via a personal account would be preferred. Opinion on this appeared to be slightly divided with 60% saying this would be their preference but 20% were unsure and the remaining 20% said no.

When questioned about the resources, students listed the practical elements: timetable and referencing guides; building map and Students' Union links as being the most popular, illustrating the importance highlighting both academic and social aspects of University life. There were significant numbers of people claiming they had not used some of the resources. This included the on stop shop ('Ask Liz') service, an element highlighted by (Mayhew *et al*., 2010) as an orientation programme success factor. However, this could also infer that the information on the *'Facebook'* group was sufficient for their needs.

Krause *et al.*(2005) note that successful learning communities rely on successful peer interaction. The virtual mentoring model did indeed appear to assist in this process. As well as the speed at which the incoming students interacted both with the group and themselves indicated this. In addition questionnaire responses from the cohort, students felt they have developed good relationships with their peers which they felt had had

a positive influence on their intellectual growth. However, just under half of the cohort felt they would not feel confident in discussing personal problems with these friends which suggests that any friendships made are not yet considered close. Despite the success of the introducing course colleagues only half of the cohort felt that the information provided on the *'Facebook'* group had prepared them for University life and only one third felt that the group had increased their confidence. Notably, a similar proportion stated they had not felt confident in posting any questions. Responses which explored relationships with the mentors yielded much lower response rates which may indicate that some form of face to face contact may indeed be preferred.

Alongside good peer relationships, Peel (2000) also stresses the importance of students developing personal relationships with staff. This was explored by the questionnaire. The staff very well thought of, with over three quarters of the cohort believing they showed a genuine interest in teaching. Smaller numbers, around half of the cohort, felt that the staff showed interest in them as people. There was also a desire expressed by the cohort for more informal and academic contact with the staff. This could be achieved through future models, where resources and/or advice could be posted to *'Facebook'* directly by the staff.

Pendleton (2005) notes how experience not matching expectation can be a factor which affects retention. In this case positive results were received. Students showed strong levels of commitment both to their learning and the University. All students noted the importance of getting an undergraduate degree, with 78% noting the grade they wished to achieve was important. Over 80% of the cohort felt they had chosen the right University with two thirds saying they would recommend the University to others and half the cohort, even at this early stage, would consider studying to Masters level. To date, no one has left the programme. However, as part of the observation process, in January 2011, one male student, on his *'Facebook'* wall, clearly expressed doubts about the programme and considered leaving. *'Facebook'* was quickly used by other members of the programme to pass on very balanced advice; this conversation was concluded by the student posting his decision to stay - a pleasing outcome for this project.

However, the observation of *'Facebook'* activity also illustrated, that very few students made use of the privacy settings on *'Facebook'*. Significant numbers of students posted some form of personal contact information e.g. email addresses, phone numbers. In a number of cases the tone and content of many *'Facebook'* wall posts would not be looked upon in a favourable light by prospective employers. These findings are similar to those of a number of US studies which warn of the potential negative implications of this (Gross & Acquisti, 2005; Kolek & Saunders, 2008; Lenhart *et al.,* 2007; Peluchette, 2010). This does indicate that, as postulated by Kolek and Saunders, (2008) there may be a need for institutions to consider the development of advisory policies on the use of social networking.

Despite, the neutral views which appear to have been expressed overall, the viability of utilising social networking to further support the learning process will form the basis of future research. This will include developing through the Treaty of Windsor Anglo-Portuguese Joint Research Programme: Communities of Learning: extending the boundaries of the learning experience through collaboration across different universities (C2LEARN) project, collaborative activity among students in the UK and students on Business and Economics programmes in Technical University of Lisbon (Gannon-Leary & Fontainha, 2010).

CONCLUSION

The previous scoping study conducted at Northumbria indicated that social networking, and in particular *'Facebook'*, had the greatest potential for supporting the academic adjustment of students. This was due both to its immense popularity amongst the student body, including international students, alongside the ability for contact with students to commence before formal student induction. A pilot virtual mentoring model utilising a '*Facebook*' group was introduced in August 2010. Action research methodologies were used to evaluate the pilot. Incoming students were sent a link to the group as part of the joining instructions and the majority of the cohort joined this group and posted queries within days of these letters being distributed. It was also observed that students quickly became *'Facebook'* friends with each other. Questionnaire results illustrated that students did engage with the materials on the *'Facebook'* group but this appears to have been over a short-time scale. Unlike, the scoping study, international students were found to use *'Facebook'* less frequently than their UK counterparts. However, this is believed to be linked to the current *'Facebook'* ban in China which in turn has led to an increased use of another site *'QQ'*. Students reported that there was less engagement with some of the resources as expected and a number of students did not feel that engagement with this group had particularly increased their confidence in starting University. However, questionnaire analysis illustrated that good relationships had been made between the students and they indicated that they had a strong commitment to the University. The programme has to date achieved a high retention rate.

Observation of students *'Facebook'* pages revealed that the vast majority of students share or post information which may be considered to not be totally safe or appropriate in a publically available context. Although, the overall outcome of the pilot has not been as positive as hoped, the researchers believe there is enough potential indicated through the strong cohort identity formed at a very early point to take forward the virtual peer modelling concept as a pre induction introduction to the University. Future models, would still utilize *'Facebook'* but a non-personal account will replace the use of a *'Facebook'* group. To account for the current ban in China, *'QQ'* will also be investigated for its potential to host pre induction materials. The resources provided could be improved to include video introductions and it is believed that academic staff could also use the resource for communication purposes. Students will also be advised on the use of *'Facebook'* privacy settings as this can protect both themselves and the institutional image. In parallel, other avenues of development will be explored including extending the use of social networking and examining opportunities for collaborative activities between Economics students in the UK and Portugal.

185 - Signs of Construction of a Professional Development Community in Language Education: A Case Study

Ana Sofia Pinho[1] and Ana Raquel Simões[2]

CIDTFF- Research Centre Didactics and Technology in Teacher Education
Department of Education, University of Aveiro, Portugal
[1]anapinho@ua.pt, [2]anaraquel@ua.pt

Abstract: The project "Languages and Education: constructing and sharing professional knowledge" evolved around the development of a community-based environment organised in thematic working groups of teachers, educators and researchers. The research purpose was to study the construction of such community, as well as the professional development trajectories of its members.

The community's dynamics were mainly based on face-to-face communication through regular meetings. Notwithstanding, the *Moodle* platform, particularly the discussion forums were used to bridge the gap in-between meetings. This study analyses the interactions (discussion forums and chat) and the documents shared in the *Moodle platform* of one thematic working group, in order to identify signs of emergence/construction of the aspired professional development community.

This investigation seeks to contribute to knowledge generation about professional development communities in language education, and puts forward possible routes to follow-up networks or partnerships which may enhance and nurture the culture of collaboration initiated within the project.

Keywords: communities, professional development, language teachers, discussion forums

INTRODUCTION

What are communities of professional development? How can their construction be studied? Questions such as these inhabit the mind of many who have interest in figuring out the most relevant settings for teacher education and educational innovation. As Zeichner (2008) points out, settings for teacher preparation and education are diverse, and involve universities, schools and communities, and teacher education programmes. In this panorama, over the years many scholars have dedicated to understanding what communities are, how they emerge, develop and become or not sustainable over time, as well as their potential to the professional development of its members and the benefits to organisations where they live in (Wenger, 1998; Wenger, McDermott & Snyder, 2002; Westheimer, 2008).

Research in this field has also focused on how technologies and internet tools contribute to the "experience of togetherness that extends through time and space" (Wenger *et al*., 2005: 2) within communities, since they strengthen familiarity and socialization in-between face-to-face encounters, fostering the experience of togetherness and sense of belonging and identity within the community.

The project "Languages and education: constructing and sharing professional knowledge"[110] shared many of these interests, and intended to understand how to cultivate professional development communities made of diverse actors in language education (researchers, teacher educators and teachers). The purpose of this project was materialised in the launching of such community, which gained existence during a whole year (2008/2009). During that period, one of the most frequent questions among the core group of the project was: is it possible to identify signs of community edification? Are we indeed cultivating a professional development community?

The study presented in this article pursues answers to such queries. Taking one of the thematic working groups of the community as an exemplificative case, we analyse the interactions of the *Moodle* platform (discussion forums and chat), as well as the shared documents, in order to identify signs of emergence/construction of the above-mentioned professional development community.

Therefore, after presenting the theoretical framework and the project "Languages and education", we describe the study carried out, which seeks to contribute to knowledge generation about professional development communities in language education. Bearing in mind the findings, the article makes considerations regarding the process of creation and nurturing of such environments, and puts forward

---

possible routes to follow-up networks or partnerships, which may enhance and nurture the culture of learning and collaboration initiated with the project "Languages and Education".

PROFESSIONAL DEVELOPMENT COMMUNITIES

The proliferation of the theme of communities in the context of teacher education roots in the paradigm change regarding how knowledge is constructed in education. This change of perspective emerges of socio-constructivist theories of learning (and authors such as John Dewey, Leo Vygotsky or Jerome Bruner), of anthropologist and cultural theories, which stress the cultural and symbolic nature of knowledge and knowing, as well as of situated learning theories, which highlight the relevance of the context and situated experience in learning processes (Lave & Wenger, 1991). As Cochran-Smith & Lytle explain about teachers' learning,

> "it is assumed that the knowledge teachers need to teach well is generated when teachers treat their classrooms and schools as sites for intentional investigation at the same time that they treat the knowledge and theory produced by others [and themselves] as generative material for interrogation and interpretation" (1999: 272).

Teacher professional learning/development is multidimensional, often conceptualised as a personal (individual-cognitive dimension) and collective (social-interactive) process, rooted in the school context, or in the context of action, and therefore deeply intermingled with teachers daily activities (Marcelo, 2009). Some authors stress such learning as related to change in cognition (knowledge, beliefs) and teaching practice, while as others highlight the socio-interactive nature of such process (Illeris, 2009; Pinho, 2008). Teachers' development is dependent on the individual's active role, and connected to processes of renewal and improvement of knowledge and action, heightened by teachers' self-involvement and commitment, and sustained by reflection, experimentation and dialogue with others (Day, 1999: 16, 19). Through such processes assumptions can be examined, beliefs challenged and professional practice strengthened (Allard *et al.*, 2007: 312). In such dynamics of professional development, Marcelo (2009) argues, different types of opportunities and experiences (formal or informal, natural or planned) are implicated and shape teachers' professional identity.

In this realm of teachers' professional development, collaboration and collaborative settings, such as communities, are pointed out as valuable strategies and contexts for enhancing teachers' knowledge construction and improving teaching practices (Allard *et al.*, 2007; Vescio *et al.*, 2007; Westheimer, 2008). Such settings can become spaces for meaningful practices, accessing to resources, opening horizons, building new trajectories and identities, or getting involved in innovative actions, discussions and reflections. Simply put, communities are considered settings where teachers would engage "their own knowledgeability" (Wenger, 2009: 215), "assume responsibility for colleagues growth" (Aubusson *et al.*, 2007), as well as develop a culture of intellectual inquiry (Fullan, 2001; Westheimer, 2008: 761).

Moreover, the above mentioned paradigm shift is also visible in the way researchers face knowledge construction in and about teacher education, realising the importance of working with teachers and of establishing new relationships and approaches between educational research and practice, as ways to overcome gaps and favour mutualism (in the sense of fostering the benefits for both parts in interaction). As Westheimer (2008) points out, the idea of community is closely connected to overcoming professional isolation and alienation, as well as to the cyclical nature of knowledge co-construction and the synergic effect related to the increasing of professional dialogue among participants (teachers, researchers, educators, administrators, students...).

But what are communities of professional development? How can they be defined and characterised?

From the proliferation of terms to a working definition

Many are the specifications associated to the term 'community'. When looking at the literature on the theme, we find references to communities of practice, professional learning communities, research communities, virtual professional communities, communities of interest, amongst others. This multiplies the problems to conceptualise community. Amin & Roberts (2008) explain what they consider to be the impreciseness of the term:

> "The status of the term as a keyword of new thinking on the sources of learning and knowledge generation seems to rest upon a certain loss of the original awareness of context and habitus (Mutch, 2003), careless use of the word community (Lindkvist, 2005; Roberts, 2006), and speculation on the

link between situated practice and learning or innovation outcomes (Handley et al., 2006). Thus, social practices of all kind in all sorts of collaborative setting and all manner of learning and knowledge outcomes are becoming folded together into one undifferentiated form" (2008: 355).

The term can therefore become an umbrella for many forms of acting in teacher education and research. As regards the notion of professional development community, we took into account that it should congregate characteristics of 'community' and those of 'professional development'.
According to Wenger, McDermott & Snyder, communities can be seen as

> "groups of people who share a concern, a set of problems, or a passion about a topic, and who deepen their knowledge and expertise in this area by interacting on an ongoing basis. (…) These people don't necessarily work together every day, but they meet because they find value in their interactions" (2002: 4-5).

According to these authors, members of a community
- Help each other diagnose and solve problems;
- Get involved in discussions (about their situations, aspirations, needs…);
- Reflect upon and explore common concerns, issues, ideas;
- Create relevant artifacts to their practice;
- Share information, develop an intellectual capital and steward knowledge ("a body of common knowledge, practices, approaches");
- Value the community as a way to keep up with the rapid pace of change and create innovation in their work;
- Develop a shared tacit and explicit understanding of their domain;
- Treasure the time spent together, value joint enterprise and collaboration;
- Cultivate processes such as coaching, apprenticeship;
- Create bonds, personal relationships, and particular ways of interaction;
- Foster diverse levels of participation and leadership, and promote negotiation (for instance, in the pursuit of interests);
- Feel a growing personal satisfaction allied to a combination of energies;
- Develop a common sense of identity, belonging, confidence and empowerment (e.g. to take risks), and direction or mission.

Moreover, communities make knowledge "an integral part of their activities and interactions, and they serve as a living repository for that knowledge" (Wenger, McDermott & Snyder, 2002: 9). They are aware that disagreement, debate and controversy are important processes for such knowledge generation. Also, communities are viewed as a setting for both commonality (homogeneity) and diversity (differentiation among members), since "each member develops a unique individual identity in relation to the community" (*idem*, 2002: 9).
Wenger (1998) considers communities are characterised for having a particular *domain*. In the case of the community referred to in the project described in the next section, this domain of knowledge is language education, i.e. the broader topic the community members focused on and developed their *practice* about. It is their "*raison d'être*" or the common ground for action, as well as the setting for the community's identity. This *practice* is, as Wenger, McDermott & Snyder explain, "a set of frameworks, ideas, tools, information, styles, language, stories, and documents that the community members share", or put differently, "the specific knowledge the community develops, shares, and maintains" (2002: 29) and that helps the community to deal with the domain.
When referring to a community of *professional development*, this development is also at the very core of the community's concern. In this sense, the community is not only devoted to knowledge generation about their specific domain, but also committed to the creation of opportunities for its members to develop professionally. Professional development, as Guskey & Huberman explain, is "a 'development process' that allows teachers to expand and elaborate their professional knowledge base" (1995: 7). Day (1999) considers it a lifelong learning process that allows the individual to keep up with change, review and renew their own knowledge, abilities and perspectives, very much interconnected with the individual's professional identity (Pinho, 2008).
Among other aspects, a professional development community creates opportunities for its members to

- Have their educational/professional practice as a source of reflection and theory generation, thus become theory builders (Lytle & Cochran-Smith, 1994);
- Validate new theories and ideas, putting them in action and assessing their feasibility, and thus develop new repertoires of/for practice;
- Reflect about themselves (their mission, identity, professional project, themselves as professionals, their representations, their prior and current life experiences), and collaboratively discover new ways of be(com)ing;
- Develop an inter-contextual and situated knowledge, namely based on the ability to interpret their worlds (Freeman, 1996), and how they respond to their context of work (Tsui, 2003);
- Get involved in supervision processes (self-supervision, hetero-supervision and co-supervision) (Vieira *et al.*, 2006);
- Foster reflexivity, criticality, enlightenment, interpretative dialogue, supported by collaboration, cooperation or collegiality (Day, 1999; Schön, 1983);
- Get involved in research, inquiry (Carr & Kemmis, 1986) or evidence-based problem solving (Cochran-Smith, 2002);
- Develop their professional autonomy and empowerment (Raya & Lamb, 2008), and to commit both to social and personal transformation by means of their practices.

Development stages of communities

Communities are living things and one must not exclude *time* when considering their development. As Wenger, McDermott & Snyder (2002) mark out, communities have a natural cycle of birth, growth and death, and the transformations that occur during that process are neither smooth nor stable. According to the authors, such development encloses stages that go from starting to sustaining the community. Thus, there are early stages of development, such as planning and launching the community, and more mature stages, which involve growing and sustaining it. Summarising, the authors mention that

> "As members build connections, they coalesce into a community. Once formed, the community often grows in both membership and the depth of knowledge members share. When mature, communities go through cycles of high and low activity, just like other living things. During this stage, communities often take active stewardship of the knowledge and practices they share and consciously develop them. As communities evolve through these stages, the activities needed to develop them also change." (Wenger, McDermott & Snyder, 2002: 68).

In this evolving process, the community experiences challenges or tensions that can be seen either as problems or conflicts, or as opportunities to create alignment among members and foster the community's growth.

In developmental perspective of Wenger, McDermott & Snyder (2002), the stages' sequence is mainly representative of what happens in community's edification and nurturing, since variations can be found according to the specificities of each community. These stages are briefly schematised in the following table:

Table 1: Community's Stages of Development (abridged from Wenger, McDermott & Snyder, 2002)

	Stages	Description
Early stages	Stage 1 **Potential**	• It begins with a group of people interested in a significant topic for their practice/professional development. This group tends to be the community's core group, which introduces the idea of forming a community to others. • People direct their attention to the prospect of creating a community and create relationships in view of a potential community. • As a sense of shared domain and passion develops, and systematic interaction emerges, members are driven by the value they get from having common interests, similar problems, and common knowledge needs. • This planning stage is characterised by: - discovery and imagination ("discovering what you can build on and imagining where this potential can lead"); - creation of preliminary community´s design and definition of a work plan, by identifying the community's focus, the topics and projects that captivate the community members; - Identification of potential coordinators and leaders (the community coordinator plays a critical role in helping the community evolve to the next stage).
	Stages	Description
	Stage 2 **Coalescing**	• The community is officially launched as it hosts community events, activities that foster members' relationships, awareness of common interests and needs, and trust, which is paramount at this stage. • The community combines already a good understanding of what already exists with a vision of future paths. • The main effort is to generate enough energy for coalescing and to reinforce the value associated with knowledge sharing. • Determinant in this incubation period is the "development of deep insight into each others' individual practice (...) and a collective understanding of the practice as a whole" (p. 85). • Coalescing also involves nurturing the community by means of a series of activities which will concur to solid foundations of the community. The leader and coordinator play a relevant role. • This is the stage in which the community shows its viability.
Mature stages	Stage 3 **Maturing**	• The main focus is the clarification of the community's focus, role, and boundaries, assuring it is not distracting from its core purpose. • There is a shift from the simple sharing of ideas and insight to the organisation of community's knowledge and its progressive stewardship. • Members develop a stronger sense of the community and the need to be more systematic in defining its core practice. • There is a simultaneous expansion of the community's domain, membership and practice. It involves the identification of gaps in knowledge and the development of a learning agenda, the organisation of a knowledge repository. • It's a very active stage for community coordinators and support staff, since many tensions emerge and the community needs to be reorganised and its energy sustained.
	Stage 4 **Stewardship**	• Besides the importance to maintain the community's energy, liveliness and freshness, this stage's main concerns are: to maintain the relevance of the domain to its members, to keep the tone and intellectual focus of the community lively and engaging, to keep it on the cutting edge. • In this stage it is crucial that the community develops the ability to have a balance between a strong sense of ownership of the domain and the openness (a solid foundation of expertise and relationships). • It requires receptivity, i.e. considering new opportunities for learning, and be open to and soliciting new influxes of ideas, approaches and members. Important in this process is not to widen the community's boundaries excessively and risk diluting its focus.
	Stage 5 **Transformation**	• This is a stage in which the community may: come to an end, by losing its members and slowly fade away; merge with other remaining communities or transform itself, and enable new communities or niches to edify. It may split into distinct communities or become institutionalised. • How these processes flow depends on the coordinator's and core members' judgment call: whether to have a 'soft ending' (avoid conversation about the community's future and let is naturally drift apart) or to keep the community alive (decide how to live on, which parts of it to foster, and the genuinely relevant issues to its members).

PRESENTING THE PROJECT "lANGUAGES AND EDUCATION"

The project "Languages and education: constructing and sharing professional knowledge" was a research project about teacher education developed between 2007 and 2010, and assumed that collaborative research and professional development in language education are powerful means of developing a working culture capable of transforming the work of teachers, teacher educators and researchers, as well as a prerequisite for environments and networks of innovation and creativity in (research in) language education. This project's main objectives were:

1. To characterize language education professionals (primary school teachers, language teachers, and researchers/teacher educators) of the geographical area of intervention of the University of Aveiro, with respect to motivation and representations about teacher education, research, professional development, collaboration and language education.
2. To build knowledge about professional development communities (henceforth, PDC) in language education, in terms of construction dynamics (organization, management, roles, etc.), as well as regarding professional development paths in the context of collaborative work.
3. To envisage future PDC development scenarios.
4. To contribute towards teacher education and research policies in the area of language education.

Main theoretical axes

The project had three main fundamental theoretical axes, as presented below (cf. http://linguaseeducacao.web.ua.pt/):

- The qualitative transformation of linguistic education practices is enhanced when those involved carry out research into their own activities and build new understandings based on the research they have done. Recognition is given to the role of research for decision-making in language education, and language education practices as a source of knowledge towards the construction of research know-how and knowledge.
- The professional development of teachers, teacher educators and researchers was seen as a priority, and it was thought that language education practices which are most able to transform participants, contexts and communities in general, depend on the ability of these educational actors to enter into dialogue with social changes, educational institutions, language learning contexts and then learn to integrate these new theories and practices into their own repertoires.
- Communities, which function as spaces where collaborative relationships and sharing take place (Day, 1999), as well as locus of construction of new professional identities (Wenger, 1998), may become change environments around joint projects in language education.

These action principles informed and structured the projects' design in its two dimensions: research and formative.

Projects' design

Research dimension

The development of the project was organised in several tasks, which involved both research and education assignments, as summarised in the following table:

Table 2: Description of the tasks

Tasks		Description
Task 1	01.10.2007/ 31.03/2008	Characterisation of the target public (teachers of pre-school and primary education, language teachers of all teaching levels, teacher educators and researchers of the team).
Task 2	01.10.2007/ 31.03.2008	Organisation of the collaboration/education/research structure (design and accreditation of thematic workshops; development of research/observation instruments).
Tasks 3, 4, 5	01.04.2008/ 31.07.2009	Setting off and development of the professional learning community (of language teachers, educators and researchers distributed through the thematic workshops) and data collection.
Task 6	01.06.2009/ 31.10.2009	Organisation of the data.
Task 7	01.11.2009/ 31.05.2010	Data analysis and discussion of the findings.
Task 8	01.06.2010/ 30.09.2010	Organisation of a national scientific meeting (for dissemination of the research results and definition of future collaborative projects and initiatives).

Formative dimension

In this context, the setting up of the project involved building a PDC consisting of teachers of various levels of education (from the early years of schooling to secondary education), teacher educators and researchers with the purpose of (i) promoting the development of a culture of collaboration between research, teacher education and the practices of language teaching; (ii) contributing to the personal and professional development of its members; and (iii) stimulating reflection on language education practices, with a view to its improvement/innovation.

This collaborative environment was organized around thematic working groups (WG), based around three topics on language education: reading, writing, and plurilingual and intercultural education[111]. These courses took place during the academic year 2008/2009 and accounted for 75 hours of work (face-to-face and autonomous) and were adapted to the blended learning method using the Moodle platform. The face-to-face sessions ran for 7 sessions and were scheduled and distributed throughout the year. They were designed to be a sharing space not only within the WGs but also between the different groups.

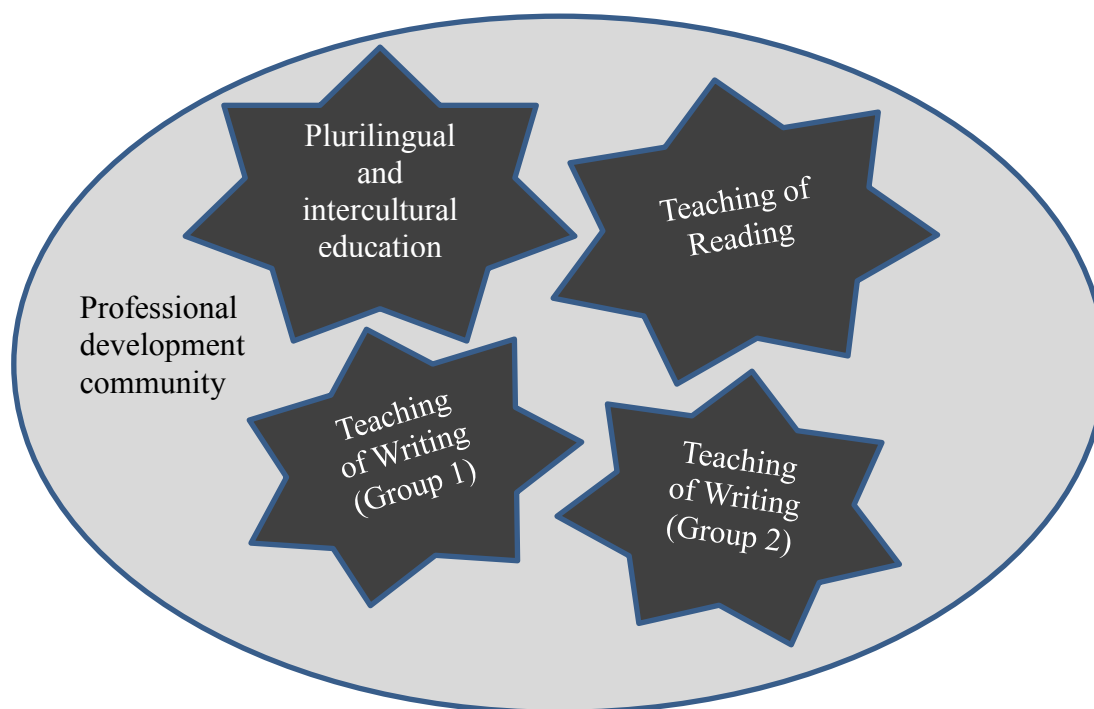
In each WG, members were organized in small sub-groups focused on sub-themes, which they jointly considered relevant to their professional development, i.e. to their research and language education practices. These sub-themes resulted in collaborative research projects which would be carried out in schools. The following figure intends to illustrate the interrelationships between the professional development community and the several thematic and self-interest groups:


Figure 1: Organization of the professional development community

In summary, the training and collaborative professional development was carried out in relation to the work (i) in PDC (a meeting place where groups gathered, among other activities, to give presentations of the work undertaken, attend conferences and engage in debates on topics of interest to the community members), and (ii) within the WG context (where the professional learning objectives and joint work plan to be developed was defined, a process interspersed with moments of theoretical and practical reflection).

THE STUDY

The context – Working Group "Teaching of Writing" (2)

The study presented here has a specific context featuring one of the working groups involved in the "Languages and Education" project, which was organised around the workshop "Collaborating in practices of teaching of writing: opportunities for professional development".

The group took the responsibility to engage in collaborative learning in order to develop their professional knowledge in the context of a Didactics of Writing. All members were language teachers (of Portuguese, English and/or French, from the 2nd and 3rd cycles of Basic Education and Secondary Schooling).

The main aims of the group were: to create enhancing conditions for the emergence of consensus about the didactics of writing; to turn those common views into a foundation to the conception of didactic devices and materials to the different school levels, as well as to the diverse involved educational contexts and institutions (see Pereira & Cardoso, 2010).

---

[111] For each of these three themes, there were three workshops with a work plan approved by the Portuguese Council for Scientific-Educational Continuing Education (http://www.ccpfc.uminho.pt/).

As Pereira & Cardoso (2010) explain, this working group followed the "Languages and Education" project's principles. It centred their work in the promotion of the capacity to collaborate based on a meaningful and systematic inquiry, in a dialogue with the members' contexts of action, in order to lead to intervention processes in schools. The group went through the formative stages common to all groups making part of the project, but developed its own dynamics. These involved:

- The sharing, analysis and questioning of experiences of teaching writing, which could consist of the planning, carrying out and evaluation of a recent writing activity, a paradigmatic writing activity, the description of the worse/better writing tasks developed (many of those practices were posted in the Moodle platform);
- Readings about the topic: writing and didactics of writing;
- Identification of guiding didactic principles of the teaching of writing and about the skills underlying the writing competence;
- Development of intervention projects within the teaching of writing and critical evaluation;
- Personal writing tasks.

In the Moodle platform, this group organised their work around the following 18 discussion forums:

Table 3: Description of the Discussion Forums

Nr.	Title	Description
1	*General forum*	General news and posts
2	*Who are we?*	Characterisation of the group (personal and professional profiles; questions focused on personal research practices and research interests).
3	*Working plans*	Presentation of the groups working plans to be carried out collaboratively.
4	*Journals*	Sharing of didactic practices of teaching of writing that were food for thought: reading and comment of the excerpts.
5	*Readings "Food for thought"*	Sharing and suggestion of reading material (by the researchers/teacher educators) (aim: knowledge expansion).
6 + 7	*1st and 2nd Written reflections*	Sharing of free-writing and guided reflections.
8	*Critical appreciation of articles / books*	Repository of synthesis, reflections, schemes, critical analysis, reading notes.
9	*Guiding principles*	Discussion of the principles guiding the developed work plans.
10	*Research structure*	Presentation of the used research device.
11	*Example of an intervention plan*	Selection of an intervention plan, which was paradigmatic of the work carried out within the workshop.
12	*Analysis of initial versions and analysis grids*	Sharing and report of the main results obtained from the analysis of the students' initial texts.
13 + 14	*Materials of Portuguese Language / Materials of Foreign Language*	Suggestion of exemplificative materials to be presented in the plenary session.
15	*Analysis of final versions*	Sharing and report of the main results obtained from the analysis of the students' final written productions (focus on changes)
16	*Reactions from students and teachers*	Sharing of the reactions of both students (about the didactic interventions) and teachers (about the developed work).
17	*Global appreciation of the workshop*	Shared reflection of the contributions and constraints of the professional development community and suggestions for future work.
18	*Abstracts for the brochure and Posters*	Posts of the abstracts and posters to get feedback (comments, suggestions…)

Methodological design

The present study analyses the interactions (discussion forums and chat), as well as the documents shared in the Moodle platform of the formerly described thematic work group, taking it as an exemplificative case (Stake, 2000) of the community developed under the project "Languages and Education". As a partial study, which needs to be complemented with further studies and the analysis of other data concerning that group's dynamics, it was guided by the following research question:

Which signs of construction of a professional development community is it possible to identify in the group's Moodle platform (discussion forums and chat)?

Methodologically, the present study resorts to a content-focused analysis (Bardin 2000), and adopts a descriptive and interpretative approach, also taking into account the characteristics of communities pointed out in the literature. In order to proceed with the content analysis, there were created 4 categories: (i) collaboration, (ii) sharing and shared repertoire, (iii) communication and interpersonal relationship, and (iv) learning and knowledge.

In the category "collaboration" there are the marks of recognition of the value of collaboration, mutual commitment and involvement in group tasks, existence of joint action in the development of artefacts or ideas and a collective sense of purpose. "Sharing and shared repertoire" relates to the echoes of sharing and the building of a set of communal resources (Wenger, 1998; Vaughn, 2007). Under the category of "communication and interpersonal relationship" are signs of existence of small talk (Gorodetsky, 2007) with the objective of socialisation and strengthening the group as a unity, as well as the marks of affection and cohesiveness within the group, trust building and sense of belonging and the netiquette (Fontainha & Gannon-Leary, 2008). The fourth category, "learning and knowledge", corresponds to the hints of a cognitive and meta-cognitive dimension (Pozzia *et al*., 2007), an atmosphere of reflexivity and criticism through collaborative discussion and the meaning making and conceptual transformation (Gorodetsky, 2007).

Findings
We will present our findings according to the four established categories, trying not only to show the signs which appear in the data analysed, but also some "voices" of the participants in the course.

Collaboration
As far as collaboration is concerned, one may identify marks of recognition of the value of collaborating for the innovation of practices and development of writing skills/competences of the students, where the participants share a common general aim, giving them a sense of identity:

> *"(…)I am really looking forward to cooperate and dialogue with my colleagues".* (F1, M8, Tuesday, 4th November 2008, 13:14)[112]; *"Hello everyone, Very tired, but still aware of our main purpose... to write about our teaching of writing. For us to reflect later on. Cheers."*(F1, M21 - Wednesday, 6th November 2008, 19:04).

The attitude towards collaboration seems to be consensual within the group, as there are no online marks of discussion about what is collaborating or collaboration, although there is a shared linguistic repertoire on collaboration, for instance: dialogue, cooperation, sharing, exchange of ideas, practice analysis.

> *"I am totally for cooperation and sharing, for the saying "union makes us strong". In order to prove this, I state an author […] The only progress is that of mutual help and complementarity. The only change is the change of perspective (Anthony de Mello, Verdades de um minuto, Paulinas)* (F1, M20 - Tuesday, 4th November 2008, 10:25)".

Despite this lack of explicit thought on what is collaborating, one may easily identify the representation the participants have on the roles within the group. When analysing the forums, though there is no role distribution, there are always the same participants to be responsible for giving feedbacks or for writing the abstracts or creating the posters.

However, there are certain tasks and processes which show that collaboration becomes a practice amongst the group, for instance:
- the schedule of meetings and of work sessions both face-to-face and online (chats);
- the organisation of the collaborative work and information about the evolution of the work that is being undertaken;

---

[112] Legend: F+number (Forum and number); M+number (Member+number); followed by the date and time in which the excerpt was posted in the discussion forum.

- mutual commitment (Wenger, 1998) and common accountability between the group members, according to the idea of sharing (for instance: *"the grid was created together in a small group. Each one adopted a document to her group of students."* - F3, M11 - Sunday, 29th March 2009, 14:44);
- the processes of negotiation;
- distribution of leadership (for instance in the coordination messages);
- the support to the learning process within a didactics of writing – through feedback, including clues to the development of the work and about the model of didactic sequence. In this particular process of feedback, there is a clear tendency to a vertical supervision (the feedback is always requested to the teacher educators), giving place to a loss of horizontal intra-group supervision within the small groups;
- creation and development of common intervention plans, where the teaching practice is shared and there are individual and collective reflections through the work;
- group discussions;
- collective reflections and research work;
- the enrolment in the research and data analysis procedures.

As far as collaboration sustainability is concerned, one can notice that there is a concern with the continuity of the collaborative work already started. Suggestions concerning the possible paths for collaboration in the near future can be found in forum 17, was well as regarding the possible expansion of interpersonal networks already created within that year. The participants also anticipate future scenarios, giving suggestions based on their experiential knowledge about the construction of the professional development community.

> *"I think it is a pity to stop the dynamic which has been created. (...) now we may try t correct some aspects which we consider that can be improved (...) it would be important to undertake some meetings to share ideas. The paths taken until the middle are so important as the complete route; and we get a better idea of what is going on"* (F17, M15 - Wednesday, 8th July 2009, 19:19).

Sharing
Sharing occurs at diverse levels and this may be a hint of the construction of common repertoire of resources (Vaughn, 2007; Wenger, 1998), and of shared professional practice. There are evidences of sharing of several elements:

(i) references to bibliography, *sites, blogs*, as well as documents, mainly related to writing, the theme of the group, both spontaneously and asked by the participants; (ii) "inspiring" literary quotations and "sayings" on writing (in the reflection platforms);
(iii) strategies and didactic materials (either in draft or in final versions) and practices for developing writing skills:

> *"I was peeking out the materials of our group and I saw the grid. I liked it very much and I will certainly use it in my classes in Portuguese Language class. (...) It also makes us reflect upon what we write in worksheets (...) Thank you for sharing!*
> (F3, M13 - Sunday, 10th May 2009, 20:26)";

(iv) personal contributes, motivations and expectations concerning teacher education and the community, as we may read from the following statements:

> *"my major aim is, as always, to learn through the exchange of experiences. [...] In this workshop, I would like (...) to analyze my practice, because I feel that I already develop much work with my pupils, since their accomplishments are notable. However, I never sat down to write about it and I think time has come!* (F2, M11, Monday, 15th December 2008, 14:14)";

> *"In this workshop I hope to learn more, perhaps to do some (...) to share experiences, to correct "mistakes"... I really want to learn about teaching my students writing skills, so that they see writing activities as a pleasure and not as a duty!"* (F2, M17, Friday, 12th December 2008, 09:12)";

(v) tensions and anguishes towards the tasks to be undertaken, as well as pedagogic questions or doubts in terms of students:

> *"The 'unrest' now is this: I am a teacher, but how may I be a good teacher? I still do not know how to teach my pupils how to write! To correct essays is a drama."* (F2, M2 - Tuesday, 3rd March 2009, 22:30);

(vi) constraints in terms of time, context or personal life; (vi) problems and successes related to teaching practices:

> *"I have some difficulty in making my pupils to write… (...) they have plenty difficulties in the learning of writing"* (F1, M7 - Thursday, 13th November 2008, 15:07);

> *I had to share with you what I am feeling... some days ago I suggested my pupils to create an acrostic in English (...) and it worked so well!!! (...) I am delighted!"* (F1, M17 - Thursday, 20th November 2008, 12:19);

(vii) personal and professional information (for instance through self-characterisation) and (viii) sub-group plans and materials under constructions and correspondent reformulations.

Moreover, members value this sharing and consider it an enriching way to create bonds and to find common interests, views and foster alignment.

Communication and interpersonal dimension

Regarding communication and interpersonal dimension, there are signs which are characteristic of community edification. We refer to the existence of "small talk" (Gorodetsky, 2007) with the aim of breaking the ice (in an initial phase), socialisation, reinforcement of the sense of group, and also of motivation for the work that is to be done, showing clear group cohesion (typical of coalescing).

In the initial phase, and because the participants did not know each other, forum 1 became the place to get some information about the others and a first step to create bonds and start to develop a common confidence, in a clear complement to the face-to-face interactions.

During the project, there was a positive reinforcement and motivation for the work, mainly from the teacher educators (as a sign of vertical supervision, again). There are hints of incentive to the sharing of doubts and of opinions about how the group work is evolving:

> *"If there are any doubts, expose them, share them... If any group wants to set a time to come to my office at the University, you may do it (...) We ask you to upload your didactic planning on moodle, for sharing and mutual help. (...) The idea is that groups share ideas, materials, doubts... and we may give some orientations to each group which may also serve for other groups."* (F3, M14 - Friday, 30th January 2009, 17:15).

In order to support and sustain the flux of communication amongst the members, one may notice the existence of some technologic strategies of enrolment (for instance, the "calls for participation", the "user-friendly language" or the operational information). The role played by some members, either as facilitators, informants, animators or group-speakers, also helped to cultivate communication.

The interpersonal dimension is thus motivated by means of tasks which aim to foster the mutual knowledge and the development of sense of belonging.

Learning and knowledge

The analysis under the third category, learning and knowledge, focused mainly on the collaborative sphere. This is enhanced by means of "dialoguing activities", which indicate the presence of a joint cognitive and metacognitive dimension (Pozzia *et al*., 2007).

The collective/collaborative discussion in the forums happens in a reflexive atmosphere, but due to the blended nature of the work, there are hints that such cognitive and metacognitive dimensions have occurred more intensely outside Moodle platform, in the working sessions. As we see for instance in forum 4, there are messages which would open up the path for the development of a greater attitude of questioning and to

the sharing of divergent opinions, or even the negotiation of different visions about the feedbacks given. As this excerpt clarifies,

> *"Last Saturday it was consensual the recognition that, despite the dynamic nature of our moodle, there are more individual messages then feedbacks, mainly in diaries. We reflected upon the importance of being read and of receiving comments... And so, we are sensitive to the need to promote retroaction. We agreed that each one of us would try to give feedback at least to one diary [...] it helps us to rethink our practices and to find new paths and principles..."* (F4, M14, Tuesday, 25th November 2008, 15:46).

The existence of significant personal and professional meaning construction may be witnessed mainly in forums 4 and 5, as we may see in the following quote:

> *"I have already seen the website you have indicated and I was surprised (...) I really need to go under a 'recycle' and to be more aware to what is going on outside the school books, affection and competences, tutorials or lesson planning"* (F4, M13 - Sunday, 9th November 2008, 21:25).

However, it is more difficult to trace conceptual mutual/shared transformation online.

Regarding learning and knowledge construction and using the perspective of Pozzia *et al.* (2007), one can identity two spheres: the group's cognitive sphere and the group's meta-cognitive one. In the first one, group's cognitive sphere, there are signs in terms of (i) *revelation* (acknowledgment of problems related to the teaching and learning of writing; presentation of opinions – for instance on collaboration), and (ii) *resolution* (search for common solutions for identified problems of teaching and learning; implementation of proposals in real situations and evaluation/reflection about developed work). In the second one, the group's meta-cognitive sphere, there are signs in terms of reflection about the learning process, the professional development and the community (for instance in forums 6 and 7) and also hints of divergence and/or controversy (Dorodetsky, 2007; Tillema, 2007)

One of those moments of tension took place in a chat session, in which the group discussed the focus of the work to be carried out, namely the choice of the textual genre that would generate the planning of the intervention projects. As the following excerpt clarifies, this was a moment of divergent views, which implied the negotiation of interests and existence of flexible attitudes within the group. The following extract is a sign of it:

> *"- We would like to know if it is possible to work another type of text, besides the argumentative one. [...]*
> *- I think that we are not all in agreement [...]*
> *- not even within the sub-groups! [...]*
> *- well...our suggestion in not binding [...]*
> *- we will mature the idea and then figure it out... [...]*
> *- but are people more inclined to the argumentative? [...]*
> *- I think that... if we do not share the textual typology, the methodology should be compulsory [...]*
> *- well...and I think it will be... at least there was not controversy about methodology [...]*
> *- it is a pity, the resistance... [...]*
> *- but in such huge groups the unity is extremely difficult"* (Chat session).

Episodes like this are considered essential in learning processes and crucial for the alignment within the group and the development of members' as well as the coordinator's conflict management capacity.

Until now, we pointed out what we considered to be the signs of community cultivation in the context of the analysed group. But, as mentioned in the introducing sections of this study, attention is needed regarding the specificity of this community. In order words, was it a community of *professional development*?

We believe it is valid to respond positively. In fact, the forums of this particular group indicate the existence of opportunities with potential for its members' professional development within a Didactics of Writing. The group's dynamics involved:

- Focus on practice – it was the starting point for the outline of learning goals and the didactic work to be developed; the practice was a generator of reflection, and therefore a reflexive practice as a shared process;
- Valorisation of theory (in dialogue with practice) (for instance, forums 1, 4, 5, 8);

- Focus on the individual, as well as on the collective sphere/path;
- Reflexive and experimental nature of the work, based on the analysis of cases through the sharing and communication of practices concerning the teaching of writing;
- (de/re)Construction of representations and of tacit knowledge (in a learning process which started from the tasks, accomplished didactical practices and constructed interactions) (for instance, forums 3, 4, 16);
- Centrality given to the planning together and the collaborative work, in a logic which fosters collective creativity (for instance, forums 3 and those related to the final plenary);
- Focus on the context and construction of inter-contextual knowledge (sharing of experiences/practices of teaching of writing and processes of transferability) (for instance, forums 3 and 4);
- Mobilization of the emotional sphere (recovery of the "circumstances, actions and experiences of affective nature", Pinho: 2008) (for instance: forums 2 and 4);
- Focus on the learning process and the students' results (for instance, forum 16);
- Introduction of research processes (in its technical and critical dimensions);
- Promotion of dialogic communication (which concurs to a social knowledge construction), and concern with the creation of spaces for common decision and "distribution" of roles…

DICUSSION AND CONCLUSIONS

The analysis of the discussion forums, as well as the chat session, indicates that such interaction spaces follow the general structure and steps of the education workshop, and of the strategy for the larger professional development community, which the group was part of.

The big number of discussion forums is a hint of the core group's (coordinator and supporting staff, i.e. teacher educators and researchers) awareness of the importance to create sites where negotiation and debate may occur, as well as the mobilisation of the members around the development of tasks, the group's work plan and agenda. As such, these spaces were important to enhance coalescence, as well as a sense of direction and identity. They were also relevant to reinforce the stewardship of the group, and the management of tensions and challenges its members were facing as they walked their path, mainly through face-to-face meetings.

What this study makes clear is that, as also pointed out in the revision of the literature, communities are living beings, and as such have their life cycle. *Time* is a major ally in cultivating communities. This group in particular, which was part of a larger professional development community, mainly emerged as a "community" itself within a specific context: the one of a research and teacher education project, which had a specific time of existence.

As an exemplificative case of what happened in the professional development community associated to the project "Languages and Education", it combined some of the traits of the stages of development described by Wenger, McDermott & Snyder (2002). Steps were carried out in order to plan, launch, and nurture the community. Within the time span of its existence, strategies were designed to assure engagement and avoid dropping out (although it occurred at the beginning), and thus ensure the community's stability. Preliminary designs for the group/community were created and restructured over time. Finding common ground for its members as well as a passion that would drive them to walk forward together was cultivated more strongly at initial moments, and nurtured as the work developed. Members found value in collaborating, and this was accompanied by them seeing new possibilities for their work as teachers and teacher educators. Events (such as plenary sessions, colloquiums) and spaces helped to "anchor" the community. The community's practices were documented, and a repository of knowledge was generated. Finally, leadership was fundamental and seemed to be legitimised by the community members, either implicitly or explicitly.

In some sense, it showed signs of vitality, with its members looking for possible ways to transform the bonds created and give way to other ways of be(com)ing. As part of the broader community, we know that some of its core members keep on working together, either in more informal or formal ways. For instance, some of the group members got involved in another project about the Didactics of Writing (see Pereira & Cardoso, 2010).

A major conclusion is that the professional development community launched within the project "Languages and Education" sowed the seeds of future communities in language education in the dynamics of the higher education institution. We would say that this project was an opportunity to facilitate the networking between teachers, researchers and language educators involved in the project and its professional development

community. People got to know better each member's culture of work, and most importantly developed knowledge about how to work together and collaboratively.

Bearing in mind the study's findings and discussion, we conclude with considerations regarding possible routes to follow-up networks or partnerships which may enhance and nurture the culture of learning and collaboration initiated with the project "Languages and Education". Steps should be taken to capitalise on the bonds and relationships developed so far, namely by developing other projects and involving other contexts and settings.

In other words, besides more informal collaboration between the project's actors, it is important that new teacher education settings emerge, such as inter-institutional networks: inter-schools networks (involving and managed by school teachers themselves, as an opportunity to get to know each others' contexts and departments and to create synergies between them), as well as school-university networks or communities (reinforcing the bonds and relationships between researchers, teacher educators and teachers).

245 - Gift-giving Technologies as a Learning Tool

Arminda Guerra Lopes

Instituto Politécnico de Castelo Branco, Portugal
aglopes@ipcb.pt

Abstract: This paper explores interaction design, a field of Human Computer Interaction, from the informatics' social and cultural points of view. The digital design and the World Wide Web expanded the contexts of the use of technologies.

This paper focus on describing the technology that changed people lives in terms of communication and interaction. With this scenario in mind, this paper will present the example of the mobile phones and social networks, which became artefacts that contributed to framed culture.

Two case studies were considered. The data gathered and analyses were made using a Grounded Theory Methodology approach.

Finally, the paper concludes by presenting the design of a gift-giving conceptual framework which can be a reflection point to consider within the design process of future interfaces. Conversely, this framework can also be a learning tool either for understanding the usability principles of an interactive interface or as an instrument to teach and motivate students in the knowledge exchange situation of collaborative work.

Keywords: Interaction design, gift-giving technologies, learning, grounded- theory

INTRODUCTION

Today, there is a new vision of the computation where the technology exists as a force that shapes our individual and social lives. The discourse associated with this vision describes a world where technologies invade our lives allowing making things that we never imagined. Interaction changed. We are facing a corporative context where the mobile technologies and the social networks modify the established standards of communication, increasing and substituting them.

It is significant that the social dynamics resulting from the use of some communication tools created a changing paradigm in people relationships. Equally, culture, constructed by human beings in interaction between each other, became important for interface design as well as within the interpretations of cultural practices of a given group when they use a product or service.

Wireless communication permitted a new way to communicate and interact with others; for example, the use of a mobile phone or social networks. A social obsession of being in contact with others is imperative. It is this interconnectivity that defines culture today. The presented studies show some considerations which are reflected in human lives and behaviour changes.

INTERACTION DESIGN

Interaction design has been associated with computing and technology, but the focus must also target on the design of how people interact with any artefact, be it an object, a system, an environment, or a consequence of the use of digital technologies or not. The aim is to support either an interaction of a person with the artefact, or an interaction among people that are mediated by the artefact. Much of what is understood about the design of digital artefacts is also applicable to non-digital artefacts.

In recent years, human computer interaction (HCI) and related fields, for example computer supported collaborative work, interaction design, and participatory design have produced an increase in interest from focusing on efficiency, functionality and usability, towards an increasing preoccupation in the aspects related to the users' experience of technology and digital artefacts (McCarthy & Wright, 2004).

Interaction design as a discipline is a result of its interdisciplinary roots: in industrial design, information architecture, communication design, user-experience design, human factors, usability engineering, and human computer interaction, which all overlap.

Interaction design is inherent in all design; it is a facilitator of interactions between humans through objects that have some sort of ability to sense and respond to human input via communication, either one to one, one to many or many to many. It occurs in the design process; within objects and designers serving interaction between people.

Interaction design is also touches upon behaviour (Saffer, 2010), the behaviour of objects and services, with how objects and services work and the behaviour of designers interacting with others.

Social and Cultural points of view
Interaction is a general model of socio-cultural phenomena. It needs signification and meaning interchanges that occurs in a space dimension of norms, values, and meanings.
New technologies are offering enormous opportunities for supporting people in their everyday lives; in which has brought a wider set of concerns and focuses on improving efficiency and productivity at work.
Nowadays, the fundamental issues of technology media or online application development have extended from traditional usability problems to wider social aspects of interpersonal contact, information sharing, participation and culturally inherent needs (Herman, 1996; Yeo, 1998; Barber & Badre, 1998; Clemmensen et al., 2007).
Cultural preferences have become one of the most significant subjects and focuses of technology development, as it slowly turns away from issues of usability to issues of fulfilling users' cultural and social needs (Bourges-Waldegg & Scrivener, 1998; Strøm, 2006).
The innovative technology, mobile communications, and the Internet play a role in most people's daily lives, being applied in diverse directions. As a result, social activities and cultural values have been manifestly influenced.
The goals of designing interactive product are concerned primarily with user's experience, which means creating systems that are: satisfying, enjoyable, helpful, motivating, emotionally fulfilling and fun. This involves understanding the nature of the user's experience as well as the users' or peoples' expectations facing a product; in which means, after, during and before the "spectacle". However, understanding a user's actions is very difficult for the reasons of people being of different sexes, genders, sexual orientations, ethnicities, nationalities, religions, social classes and educational, technical, occupational and experiential backgrounds and have or do not have disabilities. Meaning that, there is a diversity of cultural levels that must be considered within interaction design in which it is not easy due to culture also being dynamic.
Conversely, the cultural component of designing user interfaces is very important as well as user's physical capabilities and cognitive functions, but also, the cultural background and social situation of the user at the time of using the product or service.

MOBILE TECHNOLOGIES AND SOCIAL NETWORKS
In recent years the research area of social mobile and networking technologies has made rapid progress; due to the increase in development of new mobile technologies and the widespread usage of the Internet as a new platform for social interactions.
Applications of mobile and networking technologies serve groups of people in shared activities, in particular geographically dispersed groups who are collaborating on some task in a shared context. We are in the beginning of the next social revolution (Rheingold 2003).
An important characteristic of those social applications is the continuous interaction between people and technology to achieve a common purpose. Social Networking technologies join friends, family members, co-workers and other social communities together.
We no longer enter the Internet – we carry it with us. We experience it while moving through physical spaces. The networked interactions permeate our world. The notion of networked culture is seen as one of the defining characteristics of the contemporary world.
Besides the personal and social use of mobile phones, there are several examples of mobile learning presented in literature (Attewell, 2005; Coutinho, 2007; Bonk et al., 2008; Macdonald, 2010; among others) Attewell stated that mobile phones are no longer just for chatting and organising contacts and diaries, they are now pocket-sized computers and have the ability to deliver learning objects and provide access to online systems and services.
We humans are social creatures. With rare exception, we strive to relate, converse and connect with others. Social networking promotes online communities of interests and activities that promote connections between users in a more open and robust manner than simple e-mail. In this paper it will be presented the main advantages and disadvantages encountered by university students using it.

Mobile Phone as a Cultural Icon
The new era of globalization is far away from the traditional culture; however, we went back to a nomad civilization. The new communication technologies' improvement (computers, mobiles and internet) broke the frontiers.

Mobile phone as a technology has affected people's lives. Those artefacts generated a new world where gender (masculine/feminine) is melted. "Gender is both an influence on and a product of communication" (Guirdham, 1999).

Another distinctive characteristic is the sense of private and public change. Talking on the mobile phone in the presence of others lends itself to a certain social absence where there is little room for other social contacts.

Mobile phones can be a pattern of growth; a good example is what happens in Israel, as Schejter (2002) pointed out. Fortunati (2002) considers that the mobile had success in Italy because among other things it is an important means of communicative capacity, and a technology of mobility par excellence.

They are adequate to people mobility. Even so, it seems that there are a gap in the literature concerning the descriptions of the meaning of mobility, the types of mobility and the implications of different types of mobility on wireless device use. According to Gorlenko (2004) there is a traditional and a user-centred definition for mobility. In the traditional way a device is mobile if it can be easily transported; in a user centred approach, a device is mobile only if it affords mobile interaction where both the user and the device can remain mobile during the interaction.

Tamminen (2004) state that mobile context is a difficult concept to define because it has deep social roots and involving a dynamically changing environment. So, according to him context must be analysed from the perspective of the end user. Their studies took place in Finland and it describes interactional social and psychological restrictions and resources in mobility. The intention was to describe how people construct personal spaces, and how temporal tensions develop and dissolve.

The mobile phones are today more than a communication media; they have MP3 files, radio, cameras and they allow interchanging of text messages via transmitting.

Teenagers have provided a rich source of data about social practices in everyday life carried out through mobile technologies. Puro (2002) notes that comparing with other nation; the number of mobile phone per head of population in Finland is the highest in the world. Young people are considered to be a significant factor in the mobile phone business, because they have quickly learned how to operate them to an extent. Kim (2002) states that, the popularity of mobile phones, in Korea, is most evident among young people and males.

Taylor (2002) made a study of teenagers and their use of mobile phones. Through the data they suggest that teenagers use their phones to participate in social practices that closely resemble forms of ritualised gift-giving. According to them gift-giving practices can inform design, providing an initial means to conceptualise future emerging technologies.

Sun (2004) consider that it is strange to notice the recent success of text messages compared with the usability weaknesses of mobile phones such as the small display, poor input methods, moving environments, and noisy surroundings. In his opinion, the explanation is in socio-cultural contexts of use. We already knew that all human activities are embedded in socio-cultural contexts, which are not solely created by local cultural and historical practices, but also co-created by each participant's history and life experiences in the use of a technology.

Mobile technologies are already modifying well-established communication patterns, amplifying and substituting for them. Participating in the mobile information society is not only a matter of getting a phone call or a phone, but how it is used in everyday life.

The use of mobile phones is then a question of culture since they allow new habits, postures, communication, behaviours which contribute to society transformation. Also, the referred mobile mobility is more a cultural than a technological question. In this way, mobile phone migrated from its initial function of a communication device and became a symbol of style and taste of the user. However there are, some nuances in its use, for example: there are people that use it more than the PC to send emails: there are countries where it can only be used in specific locations. It has become an icon or symbol of status. It does not represent only communication but also a question of social acceptance and popularity. There are those who create affection towards it and do not seek anything else, those who identify themselves in a personal way, and there is an increase of intimacy with the others created through the use of this piece of technology. The mobile phone became the cultural icon of the digital generation.

Gift-giving rituals

People are accustomed to think in terms of what they can benefit from a given situation. Within gift giving paradigm, the gift permits to approach each person with another attitude, "What can I create? What can I give?" making part of the gift environment.

Gift-giving is one of the symbolic forms of exchange between groups either physically distributed or approached. These practices have roots in old practices where they were executed ceremoniously, to establish alliances and rivalries.

Gift giving, traditionally, refers to an object given from one person to another; with regards to increasing the amount of happiness in their life, or just decreasing the amount of sadness. This includes special days and occasions, and when somebody might need a lift.

The gifts exchanged as a social practice show, in this study, that, especially teenagers in activities mediated by telephone keeps a kind of ritual of `gift-giving', and their participation in these activities has a significant impact in the form they see and understand the use of mobile phones.

Social networks are an example of a social media, to give. The giving is among other purposes, confined to help, council, share, or anything else that provides value to the recipient.

STUDY

Two case studies were used. Case study one: how young people use a mobile phone? And case study two: are social networks a learning tool? There were about twelve young people in the former and fifteen in the latter that took part in the study.

The methods used to collect data were centred on a qualitative study; a combination of research methods was used to collect the data, literature review, case studies, interviews and observations. Interviews were conducted face to face and by email.

The aim of this research was to understand what young people (age average: 13 years old) said, and how they behaved using a mobile phone as a social communication media; and what university students said about the strengths and weakness of social networks either as a sharing way or as a communication and learning artefact.

Methodology

Grounded Theory (GT) is a general method to use on any kind or combination of data, and it is particularly useful with qualitative data (Glaser 1998). Denzin (1994) argues that GT is only one of several different qualitative research methods available to those conducting exploratory research. It offers a comprehensive and systematic framework for inductively building theory.

It was found, that nowadays, there is a vast amount of literature information concerning Grounded Theory Methodology (GTM). However, the literature differs as to how the analysis helps themes to emerge from the data. Mainly, one can found focuses on Strauss and Corbin (1990) using systematic procedures and, more recently, about Charmaz (2006) using a constructivist approach.

In order to generate GT, the researcher engaged in a rigorous and iterative process of data collection and constant comparative analysis that founds raw data brought to increasingly higher levels of abstraction until theory was generated. The method of theory generation has well defined and clearly articulated techniques for data analysis embedded with. It is precisely this clear articulation of GT techniques that have seen them become central to many qualitative data analysis strategies. It involves two phases in the analysis of qualitative data. Data fragments are compared in order to derive general descriptors or variables (concepts; categories and properties) which catch their analytically relevant properties. The idea of the approach is to read (and re-read) a textual database or observations of behaviour, and their interrelationships. The second phase is used to elaborate, refine and reduce results of the first phase. This involves connecting codes in the form of hypothesized propositions specifying conditions. Open coding is the part of the analysis concerned with identifying, naming, categorizing and describing phenomena found in the text. Essentially, each line, sentence, paragraph etc. is read in search of the answer to the repeated question "What is this about? What is being referenced here?"

Charmaz points out that GTM specify analytic strategies as followed; a few rich data sources suitable for use in GTM, and a central importance is attributed to test as data material in the form of interviews which were carried out in this study.

DISCUSSION

Data gathered and analysis permitted to build several categories, within GTM, which contributed to the design of the framework presented in figure 1.

The activities mediated by telephone are an example of a form of life routine, organization and structure around the mobile phone. In particular, in gift-giving practices telephones as well as some text messages sent by mobile phones are treated as gifts.

Some aspects are seen, in more detail; such as, the meaning of these practices, the ritual, the obligation of exchange, the alliance and friendship that is established, the status and rivalry that is assumed, the pretending figure that can be assumed and the value of the exchanges.

Figure 1: Gift giving framework

- Gift-giving sustains meaning – The act of giving converts something within us and our relationships with who receives a gift. The gift helps us to organize our memories in things that can be reached and kept; therefore, associated with stories and individuals in particular.
- Ritual exchange - is through the offer that the gift acquires its meaning. The meaning is expressed not only in the gift but also through its giver and receiver, and still in the occasional ceremony in which the exchange took place.
- Obligation of exchange - in reply to gift, the receiver is obliged to accept it, i.e. to answer. The reception of the gift demands the acknowledgment and the participation of the giver in the occasion, and more important, it is the identification of the giver's role in the vast social network. This obligation to accept, as part of the ritual of gift-giving is apparent.
- Alliance and friendship - this mechanism allows sharing emotional experiences and interchanging objects with personal meaning. The telephones can circulate and be changed without argument or negotiation (to see, to copy files, to change numbers…). The exchange implicitly demonstrates the privacy between one and the others.
- Status and rivalry - the gift is exchanged through the reciprocity principle, in which the link among people is established through an apparent contradiction. Gift-giving creates an environment demonstrating the status and rivalry; both, are kept under the obligation of the reciprocity. The receiver is obliged to interchange the gift as a form of gratitude placing itself in inferiority position. The telephone and its content as other exchanged objects are mechanisms through which one can make these fights of power and rivalry. A phone call offer, for example, can symbolize more than an intention to show affection or alliance. It may also be used to allow the giver a position of power towards the receiver.
- Pretending act – during messages exchanges, both the giver and receiver can have diverse roles: they can pretend or act as different actors. The scenario may never be identified. In this situation a fallacy world will be created propitiating several pretending stories.
- Value - the gift exchange objects by telephone confer value. An object value can be determined by the object itself. The text messages, for example, can be seen as greater or lesser value if they are written in some way (capital letters, without punctuation…). For the gifts as the text messages, the value is associated with who gave the gift and with the context in which it was sent and received. Messages of text, calls, offering a telephone, etc. are gifts, since they have value. This value is linked

with the giver, with the receiver and with the context in which the exchange, in material form, is made.

These considerations were only based on the text messages example within mobile phones used by teenagers. We could also verify what happens in relation to other object exchanges such as: touches, images, music, etc., but it was out of the scope of this study since the use of mobile phone as a user interface needs a more deep analysis.

Social networks were considered within case study two as a gift-giving practice too. It encompasses the same gift-giving categories found in mobile phone case study. However, it was verified that due to increase of social influence via this form of communication which input, is either one to one, one to many or many to many, that gifts symbolize not only aspects of the giver/recipient relationship but the givers' relationships with others in the social network.

Gifts either visual or text message are linked to objects related with the individual or group life galleries, with remembrances albums, with boxes of experiences, and with unintended culture sharing. This means that people share their personal and family photos and films with others, they exchange experiences: either personal or professional, they communicate and learn with others from different communities and cultures, they converse by being or pretending to be someone else – because in the network nobody knows, and they present themselves within the actor they want or dream to be. A series of exchanged situations can occur whether they are speaking of a gift-giving social network through gifts, remembrances, and generate obligations.

Both Internet and mobile phones interactive technologies have been appropriated for use within intimate relationships, to mediate close personal relationships, for family and friends separated by distance to maintain contact, they are popular for online dating, and for friend's finder, among other purposes. Thus, it confirms that, within the realm of gift giving: among other things, the personal is social, the private is public, the real can be virtual, and desires can be illusions.

Using social networks to communicate; university students discussed the advantages and disadvantages of using Facebook. Table 1 presents the compilation of the results which were interpreted and summarized as follows:

Table 1: Facebook Advantages and Disadvantages

Advantages	Disadvantages
Information Exchange	Virtual crimes
Experiences Sharing	False Information
Friends and Partners Finder	Virtual Relationships
Curricula Vitae allocation	Photos Appropriation
Chat	Plagiarism
Music, videos Exchange	Cyber Bulling
Mixed between Real and Virtual Life	Solitude
Culture Interchange	Propaganda
Shopping	Compulsive Vicious
Accessibility	Free Website
Knowledge Acquisition	Life Exposition
Learning platform	

Students considered that the main advantages of using Facebook are centred in the actions of exchange, sharing, using, finding, allocating, interchange, acquisition and learning. Conversely, the disadvantages are focused on nouns: crime, false, appropriation, plagiarism, bulling, solitude, vicious, and exposition.

Considering the stated actions above, one can conclude that this example of social network is an encouraging platform for learning. This social media tools are technologies that enable communication and create connections between people. It can enable social learning and make it even more powerful by capturing, recording and organizing information exchange and learning that occurs between people. Not just the act of using social media to ask a question - but the act of communicating with peers, colleagues and the larger world to seek information (Bingham 2010).

Learning can be viewed as socio-cultural i.e. as a social activity, which takes place through communication or interaction with others (Vygotsky, 1978). The impressions that learners make on each other can be seen as affected by the characteristics of the exchanging messages.

The main characteristic of Facebook is the connection recommended among people, i.e. all friends of a friend may be recommended to the user and new relationships will be established. Based on this assumption it can be said that Facebook is a collaborative environment platform. It serves as a way to discuss several themes through an ideal environment where interaction among students in the learning process is predominant; and where members in a collaborative learning environment participate, maintaining a relationship among group members, in what was suggested to. It was found that students ask each other question and discuss homework, for example: they express themselves creatively which contributes to realize that social networks are a learning support tool since users feel more free to express themselves than in a classroom environment.

From the stated arguments a gift giving conceptual framework for learning could be as follows (Figure 2). This could be a reflection point to consider within the design process of future interfaces.

From the researcher's perspective a framework does several things. The main one is to provide a set of activities to analyse information definitions for the information required in the design process phases. A list of framework requirements followed by a set of specific classifications that define the framework;

- It ties together the components of the gift giving technologies into learning components, making both processes more useful.
- It forces a design team to consider the presented categories in a way that promotes learning and more understandable interfaces.
- It may contribute to improve design practices taking into consideration that people will value design outputs.

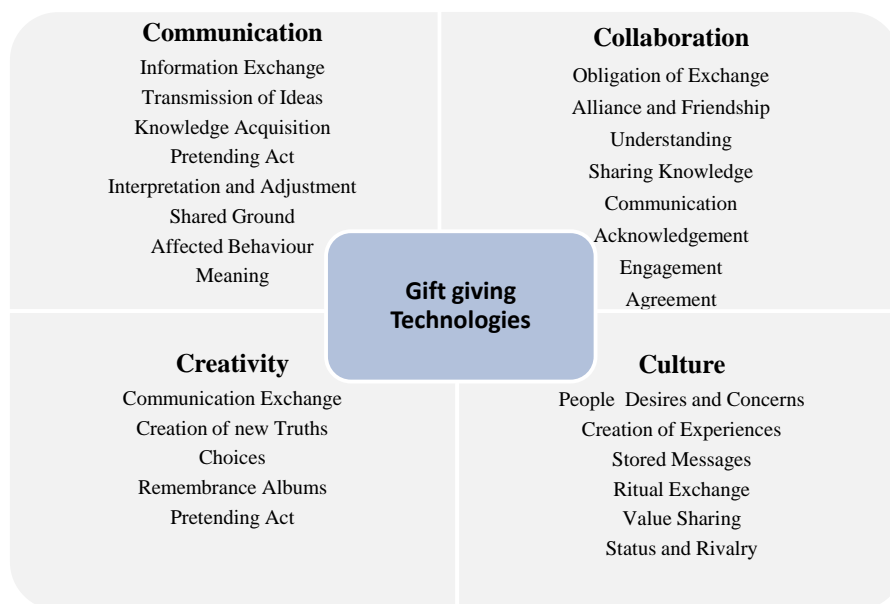
This framework for learning consists of several inter-related strands which can be synthesized in – communication, collaboration, creativity and culture (Four Cs). Each strand is seen of equal importance and is composed by actions and/or situations to provide guidance for a design process interface.


Figure 2: Gift giving conceptual framework for learning

Communication is used to give and exchange information. People communicated with words and pictures. The practice of communication is akin to gift giving technologies as well, to learning in the way that both are skills or abilities which are acquired and developed. Information is exchanged between individuals through a common system of symbols, signs, opinions or behaviours. It is the part of thinking and exchanging that redefines problems, develops creative solutions and evaluates outcomes. It is the vehicle of interaction and transmission of ideas. From the transmission of messages, one person affects behaviour to another.

Communication is a cultural practice. Culture and cultural values play influential roles in almost all aspects of human life and technologies are not exempt from these cultural effects. People' priorities, desires and concerns were shaped by their cultures. People's own cultural values, concerns and preferences influence interface design qualities and approaches. People create culture, as they create experiences and meaning for themselves and others.

Collaboration gives us a better understanding of how people work, use technologies, share knowledge, and communicate. The level of engagement denotes the alliance and obligation to react to communication.

Referring to Grice's work (1976) about cooperation, he associated it with the cooperative principle which regulates the exchange of information between individuals involved in interaction. According to him, the cooperative principle is based on the assumption that language users tacitly agree to cooperate by making their contributions to the discussion.

People used creativity as a process with one of its ingredient - communication. Each idea was visible, communicable and understandable. Nelson (2003:168) said that creativity is "often described as the creation of new and viable ideas, with the implication that this means- creating new truths – as in science."

Each feature which surround the gift giving action and their circumstances give meaning to the learning event. Each feature contains the main objectives of both mobile and social networks gift giving technology and which are the same of an intended learning platform. For the interface technology design, situations like considering (within communication) degrees of privacy, flexibility and security, and a more functional environment for collaborative learning should be considered.

Once again it is important to refer that the framework provides a comprehensive approach to consider in the design of new socio network interfaces for learning. This is the result of the data gathered and analyses within the two studies carried out and it is not a step description but rather it is a way of thinking.

CONCLUSIONS

The 'gift-giving' practices are old, however, they still frame the way people use technology in social interaction.

Two case studies were presented: one focused on mobile technology and the other on social networks. Both were considered as examples of gift giving technologies. These technologies can become accepted into our everyday lives and not just pets in the domestic environment but part and parcel of daily routines, self-images and the wallpaper of life.

After all, this paper does not contribute to new knowledge in the domain of interactive design. However, the two case studies data analysis was presented in a systematic and visual way; in which, contributed to think about a learning framework proposal to consider in interaction design processes.

The relevance was to highlight the importance of social and cultural aspects that must be considered on the design of interactive artefacts and to understand how gift giving technologies, in particular, contain social and cultural information.

247 - An Awareness-action Framework for Engaged and Transformative Schools Advancing Educational Equity and Inclusion with Communities

Jude Butcher[1], Colleen Leathley[2] and Kristin Johnston[3]

Institute for Advancing Community Engagement, Australian Catholic University, Australia
[1]jude.butcher@acu.edu.au, [2]colleen.leathley@acu.edu.au, [3]kristin.johnston@acu.edu.au

Abstract: Equity and inclusion are ever present challenges for schools and school systems. How do schools provide ease of access and a genuine welcome to parents and children who have experienced inter-generational disadvantage? What factors facilitate or constrain how schools engage with and provide appropriate support for these parents and their children?

This paper presents a research based awareness-action framework for schools and school systems to use when examining how and to what extent they are engaging with families and communities. The awareness-action framework extends beyond individual schools or school systems to community and government organisations which need to be partners in providing appropriate and effective environments for promoting children's learning.

The paper presents the research from which the framework was developed together with examples of uni-dimensional low awareness - low action approaches and multi-dimensional high awareness - high action approaches to engaging with families and communities.

Keywords: Community engagement, equity, transformative schools, communities

INTRODUCTION

Equity and inclusion are ever-present challenges for schools and school systems. Such challenges exist at the individual student level, requiring schools to provide opportunities for all students to participate and learn to their full capacity. The challenges also exist at a broader, systemic level, including having a supportive, inclusive and proactive school community.

The nature and extent of these challenges are seen both in the extent of poverty within countries such as Australia and in the nature and extent of disadvantage which people experience. The Australian Council of Social Services (2010) notes that those living in relative poverty in Australia – those whose living standards fall below an overall community standard and who miss out on opportunities and resources that most in the community take for granted – was around 11.1 per cent in the 2006 census and is increasing. The Council notes that child poverty is of particular concern, with around 12 per cent of Australian children living in households with equivalent income less than 50 per cent of the median. They also note that Indigenous Australians are especially vulnerable to poverty.

The Council's findings are endorsed by Stilwell (2006, p. 8), who reports that:

> In a wealthy nation like Australia, ... particular social groups, such as single-parent families, recent migrants from non-English-speaking countries, and the long-term unemployed, commonly experience unacceptable levels of poverty. Many Aboriginal communities have living standards more typical of poor people in 'third world nations'.

Multiple disadvantage makes accessing the opportunities and benefits of education difficult for many children. Multiple disadvantage is defined by the Australian Social Inclusion Board (2010) as the experience of at least three forms of disadvantage for example economic in terms of lack of employment and low income, social in terms of lack of support in crisis, and personal in terms of poor health or low educational attainment.

Education has long been recognised as an effective tool in helping to break cycles of current or intergenerational poverty and disadvantage (Vinson, 2007). Mastery of even basic literacy and numeracy skills is recognised as being important for reducing poverty and empowering people with the knowledge, skills and confidence to help shape a better future. In recognition of this, 'universal primary education by 2015' has been established as the second Millennium Development Goal (UNESCO, 2011).

The benefits of inclusion and social participation at individual and community levels have been long established. Maslow (1968) identified a sense of social belonging as one of the more basic human needs, recognising that it was difficult to develop higher-level needs of self-fulfilment without it. Positive parent and peer relationships have been shown to have an important impact upon social and emotional development (Cripps & Zyromski, 2009). Supportive relationships amongst peers, families, teachers and the broader community have also been shown to be helpful in mobilising social and cultural resources to support academic development (Moll, 2010).

Within the school context, positive relationships based on trust, respect and genuine interest, have been shown to positively impact on students' academic orientation and success (Darling-Hammond et al, 2005). 'Networks of exchange', predicated on trust, are similarly seen to hold 'educational capital' (Moll, 210). In contrast, communities with limited social networks have been linked to limited aspirations among disadvantaged young people (Cuthbert & Hatch, 2009).

Abu El-Haj (2007, p. 3) defines 'substantive inclusion' in the school community as the capacity to participate fully and to contribute meaningfully to all its activities. She encourages schools and educators to acknowledge, rather than to ignore differences, and to consider these from a relational and educational perspective. This implicates the broader society in the process of change, where everyone is part of the solution to educational inequality.

This recognition of the importance of relationships and networks reinforces that schools do not operate in an educational or social vacuum. Decisions and actions made by the school influence, and are influenced by, the broader community context in which they exist. In this, schools are a community within a community, and have social, educational and cultural parameters and networks in which they operate.

ENGAGED AND TRANSFORMATIVE SCHOOLS

In developing and maintaining genuine and effective partnerships and networks, schools need to think and act beyond purely transactional or school-based matters related to assets or key performance indicators. Today, many school policies and practices are driven by other pressing agendas, such as funding, scholastic performance, public image or head office directives. These not only have the potential to detract from a commitment to an inclusive school community, but also to replace it. It also negatively affects the culture and sense of community within a school. The punitive approach to accountability taken by some authorities is described by Mintrop and Sunderman:

> It has now become practical for a central planning agency, be it private or public, to set targets based on a small set of quantitative performance indicators, monitor whether large numbers of relatively small performance units reach these targets, and surgically order sanctions for underperforming units. (2009, p.393).

In contrast, supportive policies and practices, such as fees reduction, scholarships, uniforms and meal provision, can help foster a greater sense of equity and inclusion, particularly at the face value. Such measures, however, are largely transactional, one-way and isolated in nature. They have, asthe research underlying this paper shows, the potential to create a sense of dependency or obligation, even shame and embarrassment, on the part of the recipient. They may also create a sense of resentment and judgement from those in the school community who do not have trouble meeting their financial obligations, and wonder if people are really 'in need' or just playing the system. Rather than bridge the gap between the 'haves' and the 'have nots', it can expand it.

If a school is to exist more as a community than an educational institution, transactional measures to increase equity and inclusion must form only part of the solution to promoting equity and inclusion. There is also a need to ensure that such measures don't have the unintended but real effect of increasing a person's sense of separation or inequality in the school community.

To achieve genuine, or meaningful and substantive, inclusion requires a shift from a purely transactional and school-based perspective, to a more transformational, community-based one. This requires schools to stop and reflect on who they are really there to serve and how they measure 'success' - not just 'in word', but in practice. They also need to consider how well they know and engage with the members of their community, and what strategies they have in place to identify and respond, with respect and capacity, to those who may be disadvantaged or marginalised in any way. School image, performance indicators and financial concerns must be secondary to this.

The following extract is from a parent, presented as part of the research project outlined later in this paper. It demonstrates clearly the benefits to individual students and families, and the broader school community, when inclusion and equity are perceived in transformational rather than transactional perspectives, and when support is offered with dignity and respect, and as part of a community response.

My experience, or should I say our family's experience at [our local school] has truly enriched our lives. It gives each of us a special sense of belonging to a community that is safe and welcoming.

In 2007, our son was diagnosed with severe congenital scoliosis. Our lives changed from the very day that he was diagnosed and turned into a rollercoaster of emotion and pain for him. One factor that helped us through our journey was the love and support that we received from [our school] community, not just the school but the parish also.

Before we knew it we had strangers to us from both communities volunteering on rosters to cook for us, transport friends to hospital to visit our son, care for our 4 year old daughter and much more including prayers, special masses etc.

The teachers and parents of the school became a great support to us. The principal offered financial relief in the form of not having to pay school fees - he knew that I had given up my job to take on the caring role for our son and that we were financially struggling.

The teachers at the school came to visit our son in hospital and assisted with sending work for him to do to complement the small amount he was doing with the teachers in the hospital.

We never felt isolated – that was a big fear as our son was in the kids' hospital [about 20km away] and I was staying there with him. My husband was commuting but we still had plenty of visitors, not only to come and lift our son's spirits, but also to offer me the break of some sunshine and food while they sat with him. The parish priest at the time also regularly made the [long] trek to [the hospital] to see us.

When our son finally came home the help did not stop. We still had people cooking for us and helping to assist with his rehabilitation.

When he finally returned to school, he was in a wheelchair, which was daunting for a small child, however the teachers and students embraced him and were never too far away to lend a helping hand when needed. In fact they were all very protective of him and continue to be to this day, knowing that he does have a disability now, he never feels excluded from anything and the school community makes him feel safe.

This extract highlights what can be achieved, when a school community engages with respect and dignity and open hearts. In the process, those involved have the opportunity to transform and be transformed. This account shows the difference between 'walking with' and 'handing out'.

The benefits, as well as the moral imperative, for schools to adopt an integrated, community-based approach are clear. Less clear, however, is the extent and manner to which schools do this, or how they could measure or demonstrate their commitment to doing so.

It was concerns and questions such as these which prompted a Catholic diocese in Sydney, Australia, to commission a research project in collaboration with the Australian Catholic University. Seeking to gain a better understanding of how schools in the diocese identify and respond to the poor in their school, the study consulted a range of stakeholders in the diocese through survey and interviews. Participants included including head office administrators, school principals, teachers, parents, welfare agencies, clergy, school support staff and students.

In addition to providing valuable insights on how members identify and respond to the poor in their school, the study facilitated the development of an awareness-action framework. Initially this was designed to showcase the different dimensions and levels of perspectives relating to participants' awareness and response strategies with respect to the poor in their school. It became evident, however, that the framework could also have broader application and appeal for agencies and systems to examine how well they are engaging with

their community members, and possibly to assist with strategies to move towards more transformative and more integrated engagement with people who are disadvantaged or isolated.

RESEARCH OVERVIEW

The geographical catchment area (diocese) in which the research was undertaken is situated on the outer fringes of Sydney, Australia. The area encompasses some of the wealthier and poorer Local Government Areas in New South Wales.

A total of 25 Systemic schools participated in the Review. Of these, 20 (80%) were Primary and 5 (20%) were Secondary. The number of students in the schools ranged from less than 200 to over 1000.

Table 1: School by type and student numbers

Students	Primary	Secondary	Total
0-200	1		1
201-300	4		4
301-400	9*		9
401-500	4		4
501-800	2		2
810-999		2	2
1000+		3	3
Total	**20**	**5**	**25**

* 1 school = combined early childhood and primary

Data collection encompassed surveys, interviews and focus groups, as follows.

Surveys

Table 2: Survey responses by participant group

Participant group	Survey responses
Principals	25
Teachers > 10 years experience	58
Teachers < 10 years experience	34
Parents	30
Clergy	5
CEO Leadership Team	3
Welfare agencies	3
Total:	**175**

Parents, teachers, senior school support officers, welfare groups and clergy all received the same survey, seeking their views on:
- their understanding of 'the poor' when applied to members of the school community
- role(s) Catholic schools should play in caring for the poor
- factors helping Catholic schools in caring for the poor
- factors hindering Catholic schools in caring for the poor
- recommendations or suggestions to help Catholic schools assist the poor?
- three ways a commitment to people who are poor should influence the life of the school
- scope to provide additional comments.

The survey for school principals encompassed the above items, and also asked them to provide additional information on:
- the number of students enrolled in the school;
- percentage of students in the school they considered poor;
- policies and strategies in place to assist the poor; and
- possible exclusion of poor from enrolling or continuing in the school.

The survey data were collated and analysed by a research team from the Australian Catholic University, to identify common themes.

Interviews

A total of 29 individual interviews were conducted, with a cross section of participants from six selected schools. These schools were selected in collaboration with the Diocese's Catholic Education Office and conducted by the researchers. They explored similar themes to those in the survey while providing an opportunity for a more detailed and personalised understanding of key issues.

Table 3: Interviews conducted

Participant group	Number
Principals	6
Teachers > 10 years experience	6
Teachers < 10 years experience	6
Parents	2
Senior School Support Officers	6
Clergy	1
Support staff (e.g. business manager; uniform shop personnel)	2
Total:	**29**

Focus Groups / Workshops

In addition to one-on-one interviews, information was gained via five focus groups:
- focus groups of secondary school students, with 3-4 students in each group
- focus group of parents, with 3-4 in each group
- workshop with 20+ Religious Education Coordinators
- focus group, comprising ten specialists working in the welfare area. This was conducted by a leader of a local welfare agency, with responses collated on a Welfare survey form.

The focus groups provided an opportunity for the researchers to gain a fuller understanding of the issues, opportunities and challenges of responding to the poor, as per the aims of the Review. They ranged in duration from one hour (students and parents) to one morning (RECs, welfare). With the exception of the Welfare focus group, all focus groups and workshops were conducted by the researchers.

Specific questions addressed via the focus groups were:
- What is the good news around the school's (Diocese's) commitment to and care of the poor
- What are the hopes around the school's (Diocese's) commitment to and care to the poor;
- What are the challenges around the school's (Diocese's) commitment to and care to the poor?

KEY FINDINGS

The review identified varying perceptions between and within schools, in terms of what defines 'the poor' and the school's role in supporting them. Key findings, relevant to the development of the awareness-action framework, are provided below.

The broad range of definitions and perceived incidence of 'the poor' indicates the term is a subjective, multidimensional and complex one and that it is not easy to categorise or distinguish between different types of 'poor'. Recognising and addressing this broader and multidimensional reality of what it means to be 'poor' must be a priority.

While all participants in the Review were able to offer a definition of 'the poor', and saw the school or broader community as having a key role in caring for them, the varying depth of responses indicated varying levels of awareness or contact with the poor. For parents and teachers with less than ten years' experience, in particular, the responses indicated a largely conceptual or academic response, rather than a personal or experience-based understanding. Responses from principals, teachers with more than ten years' experience and welfare agencies tended on the whole to exhibit a more discerning and grounded emphasis and experience, suggesting they "engaged" with the poor on a regular basis and were fluent in their language.

The review highlighted many examples of heartening accounts of what can be done within school communities with limited resources but a good community spirit. It also highlighted many examples of unmet need and the significant impact of leadership, community engagement and, at times, conflicting priorities.

The study also identified a number of valuable insights for schools wishing to increase their equity and inclusion agenda. Four key insights, relevant to the framework, are listed below.

1. Schools need to consider many dimensions, including material and non-material, in identifying and responding to the poor in their community.

2. Schools need to consider how they can best respond in a way that meets their unique context, adapting and applying learning to their own setting.

3. To have a full understanding and appreciation of the poor requires personal exposure – it is not something that can be learned second hand but needs to come from engaging directly with people who are disadvantaged, or socially isolated. This transformative approach must extend beyond a transactional 'doing' or 'giving'. It requires relationships and an engagement, of 'working with' the poor where both the giver and receiver are open to being transformed by the other as part of a collective, caring community. Ultimately, it calls for a conversion of heart and mind.

4. Community engagement principles foster a collaborative spirit of mutual transformation and allow for partnerships and relationships to be strengthened and to contribute to the greater good of society. Schools form part of multiple systems, and need to consider the role they can best play, through engaging for mutual benefits, with the broader educational and social systems and networks in their environment.

This requires:
- schools building upon what is working well, and addressing hindering factors;
- stepping out of the professional role and engaging with the poor in their own spaces and at their level;
- engagement with community partners in a spirit of goodwill, respect and mutuality;
- a sustainable, long-term versus short-fix approach;
- cohesive school communities and leadership teams, demonstrating a shared commitment to the inclusion and respect of all and practising by example;
- flexibility, in considering different approaches for different population groups;
- developing a shared language being mindful of the connotations of particular words or terms; and
- open hearts, eyes, ears and mind.

AWARENESS-ACTION FRAMEWORK

In reviewing the responses and emerging themes from the research study, two main dimensions stood out in terms of a school's approach to identifying and engaging with the poor:
- Awareness – knowing who and where are the poor; and
- Action - factors that help or hinder; strategies and recommendations for improving care.

The dimensions are inherently intertwined, in that it is difficult to respond if not first being aware, and that awareness itself is of limited value if no action is taken.

When reviewing participants' comments in relation to survey or interview questions, it was apparent that they varied in the type and level of complexity, engagement and ownership they exhibited. Some responses appeared to be somewhat uni-dimensional in nature, lacking an empathy or exposure to the relevant issue or people. In contrast, some responses exhibited a multidimensional understanding and empathy, indicating the participant had not only personal exposure and engagement with people who are poor, and familiarity with the issue in question, but also a level of efficacy in working within it. They also tended to emphasise a community approach and sense of ownership.

This contrast is evident in the following survey extracts, in relation to the question 'what do you understand 'the poor' to mean when applied to members of our school community?':

1. *Those less fortunate than others. Families experiencing financial hardship. (SSSO, JC)*
2. *I believe that 'the poor' in our school community is relating to those families that are grossly affected by extreme difficulties. These difficulties do not necessarily have to do with financial ones, but can be due to dealing with chronic illness, physical, emotional, or a combination of all the above. (Parent, QC)*
3. *'The poor' are those members of the school community whose income is at a level where meeting the general financial obligations of school life is a great hardship. This includes uniforms, equipment, fees and excursions. They may also be financially illiterate – unable to prioritise spending appropriately. Families who suddenly find themselves losing income through death or*

loss of unemployment may also experience great financial difficulty and require emotional assistance during this time as well. (Teacher >10yrs, QF)

4. *The poor within the community can be defined as those who struggle financially but also those who are spiritually poor. Generally, those who are struggling financially are those who pay what they can in terms of fees and school costs but also those who give in other ways, eg their time, food, preparation, volunteer assistance. These people are humble yet happy of heart. Those who are spiritually poor are those who are seeking something more in their lives and yet may be at a loss to name or act on it. (Principal, LD)*

It was also evident that the comments could be rated on a low-high scale, depending on the level of complexity, understanding and familiarity they exhibited within and between the awareness-action dimensions.

Within the awareness dimension, for example:

- a 'low' level would demonstrate limited (one-dimensional) knowledge or personal experience, and a situation where those in need in the school or community went largely unrecognised. Understanding would be largely conceptual versus personal in nature.
- a 'high' level would demonstrate a more personal knowingness of people and their circumstances, where people in need are recognised in a compassionate, discreet and sensitive manner. Understanding would be largely empirical and personal in nature, demonstrating a high level of familiarity and efficacy.

Similarly, within the action dimension:

- a 'low' level would be one where the response is limited (one-dimensional), or largely transactional in nature. This would include referral to another support agency, anonymous donations or no response at all.
- a 'high' level would be one which is personal and interactive, allowing for mutual transformation and delivered with dignity and compassion.

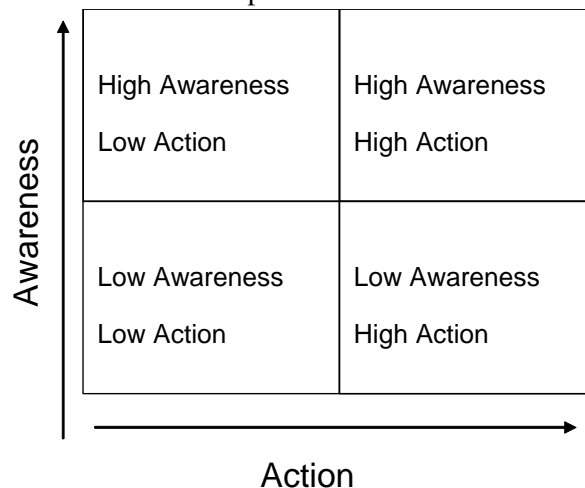
Given the identified rating schedule and the recognised interplay between the two dimensions, the following awareness-action matrix or framework was developed.


Figure 1: Awareness-Action Framework

In reviewing the survey and interview responses from participants, it was possible to 'map' them to the matrix, depending on their awareness and action levels. Responses that displayed what could be considered acumen and skill in knowing and responding to the needy in their community, for example, would be more likely to sit at the higher (right hand corner) end of the matrix. In contrast, responses demonstrating a lower level of familiarity or experience, or being uni-dimensional or isolated in nature, would more likely sit at the 'lower' end of the spectrum.

An example of how sample quotes map to the framework is provided in the following table:

Table 4: Action-Awareness Framework: Low-High Levels

High Awareness; Low Action	In-between:	High Awareness; High Action
Example quote: "The word 'poor' brings to mind 'disadvantaged', 'need', 'lacking'. As with any community our school community is unique – affected by demographics, multiculturalism, economics, language and social issues – all members of our school community at some point in time would be 'poor' in these areas" (SSSO, XD).	"There are many dimensions to the notion of 'poor' including spiritual and emotional poverty. Poverty implies a deprivation of something, so people can be poor if they are deprived of services, opportunities or access to reasonable standards of living. In regard to school communities in our Diocese, I believe that these non-material types of poverty have been well identified and targeted to date. They are still problematic but they are, at least, in the general consciousness. The real issue is that of material poverty. Those with little or no money, often fuelled by unemployment and other social issues related to poor education, language, immigration, family breakdown, substance abuse, lack of social support, etc. There are many people with little or no money or assets who need direct intervention and assistance from our school community." (Welfare, #4)	Example quote: "The poor within the community can be defined as those who struggle financially but also those who are spiritually poor. Generally, those who are struggling financially are those who pay what they can in terms of fees and school costs but also those who give in other ways, eg their time, food, preparation, volunteer assistance. These people are humble yet happy of heart. Those who are spiritually poor are those who are seeking something more in their lives and yet may be at a loss to name or act on it. (Principal, LD).
Low Awareness; Low Action Example quote: "Don't support helping those who claim to be poor but don't help themselves or are after handouts – hard to distinguish these though." (Parent, XC).		**Low Awareness; High Action** Example quote: Ability of school to care for its 'poor' has a strong relationship with how it can connect to its community. Need to look outside traditional school structure to provide greater innovation and access to school resources (Parent, YE)

POTENTIAL APPLICATION OF THE FRAMEWORK

While initially intended to act as an organising tool for the data, it became apparent that the framework could also act as a useful tool for assisting schools (or systems or departments) to consider where they currently sit on the framework and how they might enhance their awareness and action levels.

The tool has both structure and flexibility to identify and assess relevant measures and criteria for 'high' and 'low' dimensions, much as a marking rubric. This could be applied to just the awareness and action dimensions, or could also encompass sub-dimensions, such as complexity (recognition of single or multiple dimensions); integration (whether strategies are predominantly isolated or linked); attitude (respect and dignity or judgemental); effectiveness (do the strategies seem to be working); and process (transformational versus transactional). Some sample questions that may assist in this process within each dimension are below:

Awareness:
- How well do we know the members of our school community;
- If I was a member of the school community, would I feel comfortable approaching the school for help;
- What strategies do we have, or can put in place, to identify those in the school community who are struggling and require assistance from the school community;
- How do, or can, we reach out to the poor in the community who feel excluded from attending or participating in the school;
- Is our perception more inward or outward looking;
- Do we use language such as 'we' and 'our', or 'they';
- Is our definition of 'poor' too narrow or too broad;

- Do we have an understanding and appreciation of the broader context;
- How do the poor know what avenues are available to them if they require assistance;
- How do, or can, we assure struggling families that the school will support them with dignity and respect;
- How do, or can we, identify those who are in real need in the school community;
- How do, or can, we engage effectively with our school community (including parish, feeder schools, broader community) to aid identification with dignity and respect;
- Are we proactive in our approach, or rely on others to come forward with information?

Action
- When we become aware of those in our community needing assistance, how do we respond;
- Is this something we do often and comfortably;
- Are our actions done with respect and promote dignity;
- Whose needs do our strategies really serve;
- Do those who receive our assistance feel supported and welcomed;
- Are we willing to be changed by the encounter;
- Is our action essentially transactional or personal and transformational in nature;
- What practical and pastoral strategies are, or can be put in, place to respond those in the school community who require assistance from the school community;
- How do, or can, we work effectively in partnership with the parish and broader community to enhance the lives of our school members;
- Are our policies and practices really engagement and partnership or one-way assistance;
- Where is the potential for a systemic and integrated response;
- What opportunities are we providing;
- What opportunities are we missing;
- What resources do we have, or could put, in place to respond more effectively; and
- Do we have a range of strategies, and a flexible approach?

Balancing available and required economic, human and procedural resources across both dimensions also need to be considered. Possible questions to ask here are included in Table 5.

Table 5: Economic, human and procedural resource questions

Economic:	• Can existing resources be better utilised, distributed or shared; • How can schools provide pastoral and fee-relief support while also ensuring they are able to operate within budgets; and • Are fees and associated costs reasonable and affordable?
Human:	• How do we care for the carers; • Is the 'load' distributed or carried by a few; • How do we ensure we don't overload those providing care; and • Is size of the school a factor in terms of being able to identify and respond to the needs of the poor?
Procedural:	• What strategies do we have in place to help identify or respond to those in need; • How do we facilitate a positive transformation so that each learns from, respects and enriches the other; • What policies, procedures and structures need to be in place to support our work in this area; • How can we use 'word of mouth' in positive ways; and • Are some approaches more effective than others?

It is perceived that a key benefit of the framework is in providing a structure and opportunity for honest and healthy dialogue by schools (and departments or systems), in looking at the ways they identify and respond to the needs of 'the poor' in their school.

Using the criteria as a guide, schools could assess where they currently sit in the framework, and consider opportunities for moving to a higher level on a particular dimension. The tool could also act as a progress monitor, with schools and the system being able to compare progress across time periods, schools, classes or programs.

It is to be noted that the tool is embryonic in nature and will benefit from further development and testing. The following factors also need to be taken into consideration regarding its application:

- Non-articulation of a sentiment does not mean it does not exist.
- Articulation of a sentiment does not mean it is in place, or is perceived to be effective by those it is designed to serve.
- It is possible to reduce rater bias and increase objectivity by establishing relevant criteria before self-assessing (perhaps using or adapting the items and questions listed above) and by approaching the task with humility and honesty.

CONCLUSION

Schools are microcosms of our broader society. They are communities within communities or communities engaging with wider communities. All schools, whatever their economic or demographic base, will have students who are 'poor' or 'in need' with this poverty often being an experience of multiple disadvantage. The challenge, and the opportunity in many ways, is for schools to identify and engage with these children and families in a timely, respectful and mutually transformative way.

Research cited throughout this paper highlights clear benefits to schools, students and the broader community in adopting a relational, integrated and transformational approach to equity and inclusion. This involves looking beyond individual people or transactions, to a broader community-engagement and collective response. It reflects the difference between a 'walking with', rather than a 'handing out'. In the process, all are transformed in beneficial ways.

Adopting such an approach requires engagement with and awareness of the other, reflection upon one's own school, and action. It involves assessing how well a school currently engages with and responds to those in need in their school community. It also involves considering future strategies, and an avenue for reviewing progress.

The awareness-action framework deriving from research introduced in this paper is offered as a tool, for facilitating engagement, assessment and action in a relational context. It recognises that awareness and action are intertwined with regards to equity and inclusion – the presence of one necessitates acknowledgement of the other. Its semi-structured nature is designed to provide for both consistency and flexibility of approach. It also encourages schools, and broader systems, to consider the complexity, integration and dignity of their approaches.

The extent of poverty and the multidimensional nature of disadvantage in societies requires schools to be able to be proactive, respectful and open in their engagement with families and communities. The awareness-action framework derived from this research provides schools and school systems with a self-assessment tool for examining whether they are uni- or multidimensional in their engagement, awareness and action and identifying ways in which the schools need to be transformed if they are to be proactive in adopting a multidimensional approach to engaging with families promoting equity and inclusion in education.

Teacher educators are also able to employ the awareness-action framework in the development of teacher education programs and structuring student teachers' school-community experiences. The framework can also be used as a tool for student teachers' self-reflection upon their engagement with and understanding with a school's wider community.

Abstract: The contexts in which educational practices are developed in school, and the concerns about the teachers' work are characterized in various and very peculiar ways. The realities experienced by workers in education at their workplaces, the way they conduct their careers, their life histories and conceptions of education that assume significant influence in the organization and systematization of teaching. These are recurring issues socialized by researchers in different countries. What draws attention to some research is the gap still existing between the theoretical propositions, and the real contexts and needs of everyday work. Some generic and abstract propositions about how teachers' work could be developed in schools have prevented, at least in the Brazilian educational context, more consistent and coherent actions. Perhaps it is due to the weaknesses of public policies on continuing teacher education and permanent professional development, as well as the absence of information or knowledge about the educational practices developed by teachers. There are studies that point out the need and importance of establishing investigative communities of learning, and more robust and autonomous teacher education initiatives. Related to this concern, our main focus as authors of this paper is the intervention in school Physical Education (PE), because some doubts and concerns persist when we ask how are the teachers' work and its relationship with teaching and research, and also about their own professional development and the students' learning. Investigations with this concern have gained ground among some researchers and teachers who describe themselves as researchers of their own practice in the last two decades. Can such teachers-researchers, in collaborative contexts of investigation on their own work, to develop educational practices that have significant expectations for their school students to become students-researchers? In this paper, based on two ongoing Doctoral projects in Brazil, one in Education and one in PE, our objectives are to present preliminary aspects, and discuss clues on how teachers organize and systematize their educational interventions significantly while working collectively. This qualitative research has the methodological background of the action-research process, because the authors problematized their own work and formulated an action plan in order to make public the results referred to concrete changes in the analyzed realities. Both investigations used similar procedures, such as the technique of focus groups, interviews, interpretation of images and documents, and analysis of autobiographical records. Preliminary results indicate that action-research is an appropriate method to support the teachers' work, concerning the quest for improving teaching quality and teacher autonomy. It features that teachers' life history is relevant to deepen contextualized critiques on their own work, and to consider the research as inherent in the teaching work. It also points out the need to assume explicit commitment to meaningful learning in order to empower subjects to intervene in their own realities, and consolidation of collaborative partnerships between teachers-researchers who work with PE. Therefore, considering these aspects of our research, we believe that the educational process of the student-researcher also involves the permanent education and development of the teacher-researcher.

Keywords: Peer education; Action-research; Teachers' knowledge; Physical Education

INTRODUCTION

The contexts in which educational practices are developed in school, and the concerns about the teachers' work are characterized in various and very peculiar ways. The realities experienced by workers in education at their workplaces, the way they conduct their careers, their life histories and conceptions of education that assume significant influence in the organization and systematization of teaching. These are recurring issues socialized by researchers in different countries.

The state of art in Brazilian academic production about school Physical Education (PE) professional development, as revealed by Ananias, Venâncio, and Sanches Neto (2011), indicates that the analysis of curriculum, teachers' work, and students' knowledge could be enhanced by coordinated efforts of investigation. Such purpose corresponds to our Doctoral projects' common thematic – which is going to be detailed in this communication – dealing with the perspective of teachers' preparation curricula in Higher Education, collective analysis of teachers' work in Elementary and High School, and investigation on students' knowledge.

We have the assumption that the underlying scientific reasoning for teacher preparation has implications in the teachers' work and how students develop their knowledge from PE classes. We understand that the sum of these factors do not correspond to the problem itself, because each process – curriculum dynamics, teachers' work, and students' learning – is idiosyncratic.

Further analysis on standardized curriculum for teacher education may reveal important aspects about the discursive reality of the academic *métier*, culminating in the application of theories learned in undergraduate teaching courses. In the other hand, further research on teachers' work can reveal aspects of the school's everyday pragmatic reality, which is different from academic appointments.

Teachers themselves may reinforce the rhetoric to seek their continued professional development in Graduate courses. That way, the fields of academic research and school work have increased their borders increased, because we know little about the educational intervention and what is actually learned by students in PE classes.

Although specifics, the Theses have methodological strategies with collaborative partnerships and focus groups, with little reference on the specific topics according to Brazilian databases. Internationalization may lead researchers to seek foreign theoretical referential, what could direct the academic production to authors, theories, and research that focuses on global issues, rather than the reality of Brazil.

We noticed that consideration of other countries' reality, however, can promote understanding of the problem from a more advanced standpoint. In addition, the thematic suggests studies *in loco*, because there would be analysis and interpretation of the converging problem between the investigated fields.

RESEARCH PROBLEMS

What draws attention to some research is the gap still existing between the theoretical propositions, and the real contexts and needs of everyday work. Some generic and abstract propositions about how teachers' work could be developed in schools have prevented, at least in the Brazilian educational context, more consistent and coherent actions.

Perhaps it is due to the weaknesses of public policies on continuing teacher education and permanent professional development, as well as the absence of information or knowledge about the educational practices developed by teachers. There are studies that point out the need and importance of establishing investigative communities of learning, and more robust and autonomous teacher education initiatives.

Therefore, we make ourselves the challenge to examine together the common thematic of our research, dealing with similar methodological aspects and specific problems, with two foci: the teachers' work, understood in its relation inherent to research; and the students' learning, understood as inherent to their school work.

About the Focus on Teachers-Researchers

Given the scope this research could contemplate addressing the methodological diversity on teachers' work, it is useful the research problem delimitation as well as the specific objectives of this investigation.

For Contreras Domingo (1994), there have been times when what defined the problems of scientific research was a dissonance between what the reality reflected and what was intended for it. So when one sees something he/she wants to modify or improve, there is the need to define two things: an intervention context and a meaning to the intervention, or a value orientation.

According to the author, what makes us understand something as problematic is not only in reality but in the relationship between the reality and our intentions or needs. What concerns us is its difference with respect to what we would like it to be.

Moreover, Contreras Domingo says that analyzing a problematic situation does not require the elaboration of an understanding of the situation. But doing it so requires in relation to our ideas and intentions. To analyze a problem requires, therefore, examining further the nature of our claims, its assumptions, and implicit principles. It is essential, in this view, discuss our ideas in light of the data we gathered, and not only discuss the data in light of ideas.

A basic formula of analysis and reflection would be the analysis of the propositions which we use to understand the situation as problematic, questioning what we would normally take for granted about our sense of reality. To analyze the data means analyzing the collected information and question simultaneously our comprehension schemes that make it intelligible. It is from this position that we can present alternative interpretations of the facts collected facts (Contreras Domingo, 1994).

For Winter (*apud* Contreras Domingo, 1994, p.18) this approach will allow us to learn from experience, learning from data instead of making it fit into preconceptions already consolidated and closed to criticism. This way we can avoid transforming the data according to the previous categories of our thinking, without the possibility that these categories can be transformed by the data.

The issue that underpins our research on teachers lies specifically in how a group of "teachers-researchers" systematize their pedagogical work in relation to the PE's curriculum dynamics. The problem reminds the concrete work of these teachers, specially their ways of organizing teaching and research in a permanent and collective professional development process.

This problem involves investigating how each teacher dialogues with what is discussed in the group (collective subject), since there are peculiarities in their contexts of work. So, how do teachers appropriate what is discussed by them? And whether they produce valid knowledge for themselves by doing this? What does each teacher effectively do with such knowledge?

Besides these questions, we need to ask more specifically: How the teacher deals with the pedagogical content knowledge – which would be the first category of teachers' own knowledge for Shulman (1986, 1987) – or how he/she deals with the teaching knowledge itself – that would similarly be the proper knowledge by teachers for Tardif (2002) – to establish the theories of action (TA) and theories in use (TU) during his/her everyday work of PE curriculum systematization?

For Shulman, also analyzed by Borges and Tardif (2001), the second category refers to curricular knowledge, and the third category refers to knowledge that the teacher elaborates on the student. The investigation of "teachers-researchers" can also contribute with evidence in this direction.

Apparently, mediation is seen as something similar to mentoring for Tardif (2002), so the mediation between school and university would be concern the "academic", but for the group of "teachers-researchers" there seems to be mediation in another way, it seems that the teachers go directly to the production of knowledge and practice. The teachers' ability to produce their own knowledge is precisely what has been called teachers' knowledge

One must question *whether* and *how* teachers create "models" for teaching? And what if such models have validity or potential for generalization from the centrality of pedagogical practice?

While we can move in this direction, it also assumes a limitation, because by one side it would be relevant to focus on teachers' knowledge, and by other side it would be relevant to focus on students' learning. As the work of teachers is only achieved with the students' effective learning, there is a more advanced perspective that would be necessary to analyze closed to the knowledge developed by students, but that purpose is beyond the scope of this investigation on teachers.

There is currently at least one longitudinal qualitative research in progress with this perspective and depth that could point to evidence on this topic (Venâncio, 2010). Even more advanced would be to investigate the consistency of propositions from the concrete work of teachers with students, expanding the theme for the collective perspective. A collective research project with similar characteristics is being developed by the group of "teachers-researchers" in this moment.

About the Focus on Empowered Students

We can infer that Brazilian PE's different theoretical and methodological propositions have not yet realized the real needs for thinking the movement's subject. However, we emphasize the importance of Kunz's (2004) critical-emancipatory (empowering) proposition that starts from the perspective of the subject (human being) and his/her intentions set with and within the world.

We noticed with this assumption the possibility to bring together the concepts of Charlot (2000, 2005) concerning the relations with knowledge from the sociology of the subject, the concepts of Freire (2002) on educational practices, and the Self-Movement concept by Kunz (2004, 2006).

Our focus while researching on students' learning is seeking to describe and interpret *whether* and *how* a teacher-researcher and a group of students attribute meanings and senses to the relationships with knowledge *with* and *within* PE classes.

This research is going to be developed around the description and interpretation of the pedagogical practice by the own researcher during her work in one elementary school, seeking to reveal how students' relationships with knowledge are manifested.

INVESTIGATIVE OBJECTIVES

Related to these research problems on teachers and students, our main and common focus as authors of this paper is the intervention in school PE, because some doubts and concerns persist when we ask how are the teachers' work and its relationship with teaching and research, and also about their own professional development and the students' learning.

Nevertheless, it is necessary to explicit our objects toward both investigations facing teachers' and students' idiosyncrasies.

About the Focus on Teachers-Researchers

This research aims to describe and interpret the knowledge produced by teachers who research their own teaching practice. The purpose is to investigate how these teachers work daily to produce their own knowledge and principles to organize the curriculum. It is questionable as well: How do the "teachers-researchers" systematize their work? How do they work daily in teaching and research?

About the Focus on Empowered Students

The general objective consists in understanding how students attribute meanings and senses to the relationship with knowledge elaborated *with* and *within* PE classes.

The specific objectives consist in: Identify and interpret which knowledge is elaborated by the students *with* and *within* PE classes; identify what relationship interpret what relationship with knowledge the students learn from the experiences in PE classes; explicit, analyze, and interpret what is the knowledge *with* and *within* PE from the subjects' perspective (teacher and students) interwoven in one shared educational practice.

For this, we will recollect the path of those subjects, assuming that there is no student without teacher, and both are inserted in an educational practice, and focusing on the attribution of meanings by the students in relation to knowledge in the context of educational practice shared with one teacher-researcher.

RESEARCH METHODS

Investigations with these concerns have gained ground among some researchers and teachers who describe themselves as researchers of their own practice in the last two decades. Can such teachers-researchers, in collaborative contexts of investigation on their own work, to develop educational practices that have significant expectations for their school students to become students-researchers?

In this paper, based on our ongoing Doctoral projects in Brazil, one in Education and one in PE, our objectives are to present preliminary aspects, and discuss clues on how teachers organize and systematize their educational interventions significantly while working collectively.

This qualitative research has the methodological background of the action-research process, because the authors problematized their own work and formulated an action plan in order to make public the results referred to concrete changes in the analyzed realities. Both investigations will use similar procedures, such as the technique of focus groups, interviews, interpretation of images and documents, and analysis of autobiographical records.

The relation between both theses' methodological frameworks emphasizes the issue about the subjects' empowerment, from their interaction and manners of appropriation and influence onto the world.

Working with focus group seems like a possible way to bring up the dialogue among subject holding to discussions about their experiences. It has been a method already used in PE investigations, with the possibility to "call" other techniques for gathering data, such as individual interviews.

TEACHERS-RESEARCHERS AND THEIR KNOWLEDGE: SEARCHING FOR THEORETICAL AND METHODOLOGICAL REFERENTIALS

For the purpose of investigating teachers' work, particularly the knowledge that is developed in practice, the research of Borges (2004) walked the same way proposed by Schön (2000). Therefore it seems pertinent to examine closely the author's work to mark the relations between the paradigm of "teacher-researcher" and investigations into the professional field of PE.

To reveal the knowledge for the professionals themselves through research brings a possibility of mobilizing the entire group of teachers. We would go further and mention that the revelation of such knowledge could also be given *by* teachers themselves.

In the case of teachers, such knowledge informs and guides their activities. Specifically in the knowledge elaboration by PE teachers (Borges, 1998), it is worth investigating whether the same effect seems to be

traced in the process of knowledge development by the group of "teachers-researchers" with their collective mobilization.

According to Borges (2004), all research problem falls within a theoretical framework from which emerge the issues that afflict the researcher. The problem defined in her research focused on the teachers' knowledge, initial preparation and work.

For that author there are two ways of analysis as references for research: preparation and work. Both aspects are so inextricably linked to TA and TU, and in the case of "teachers-researchers" it should be investigated whether both are considered part of their work itself: the process of continuous preparation of the "teachers-researchers" is part of their daily work?

Among the investigations on the knowledge, preparation and work of teachers, Borges (2004) mentions that there is research that fall within one or more methodological approaches. To investigate the group of "teachers-researchers" and its set of TA and TU, over an approach could be envisioned, but initially the emphasis would be on the perspective of research on *teachers' thinking* with collaborative partnerships.

Other kind of research seems relevant too, but with another type of limitations. For instance, in research on teacher behavior although knowledge is taken away from the teacher, the focus in dealing with contents and methods could be related to the discussions in the "teachers-researchers" group. The limits of these studies fall on the subjective aspects established in teaching situations and lightly esteemed in the investigations, but that may be relevant to the group.

In research on teacher cognition it is required to examine how teachers learn, understand, utilize, reuse and transpose information. These processes correspond to the cognitive development of TA and TU by the "teachers-researchers". Still, the symbols investigated in this type of study could be associated with the "codes" shared within the group, e.g., as a graphical representation of the thematic contents sets (see *Figure* below).
The figure refers to the graphical representation of the thematic contents' systematization, which is how the autonomous group of "teachers-researchers" collective has been planning and organizing the daily work

Some limitations fall into the representations and modeling of teacher knowledge, which precede actions. That way, the TA would come *before* the TU, which contradicts the urgency of the teachers' daily work. The direction should be cyclical, beginning with the TU, following through TA preparation, and returning to TU on a process of constant re-elaboration with greater rigor each time.

Other limitations stem from criticism of predictability given to teaching situations, negating the teacher's personality, but introducing the idea of meta-cognition. More recent studies in the context of cognitive theories could also be involved in the investigation of *teachers' thinking*. The idea of meta-cognition may be related to the processes of reflective teaching and action-research, and we could check if both are used both in educational intervention and in research on teaching practices conducted by the "teachers-researchers".

Research on *teachers' thinking* aims to tackle the mental processes and meanings (TA) for the actions of teachers (TU). Borges (2004) explains that research on *teachers' thinking* deal with the way teachers think and solve everyday problems related to education, planning, beliefs, personal history and search for meaning. Amidst citations of scholars concerned with the thinking of teachers, Shulman's work on pedagogical content knowledge relates closely to our research problem.

There would be something yet to be done in this research field, according to Borges, with the need to clarify basic concepts of sub-paradigms, distinguishing, for example, the steps of reflective thinking, the thinking about teaching and social conditions, the anticipatory thought of action (TA), and individual and collective reflections. It is worth questioning: Whether these issues may correspond to the questions of "teachers-researchers" on their professionalism guided by assumptions based on action-research?

However, the author seems to have a paradigmatic vision on the understanding of basic concepts. We question at this point whether her standpoint is still needed for scientific research, which seems to operate by indexes instead of paradigms (Rosenau, 1992).

Borges (2004) also explains the need for the professionalization of teaching and advocating the implementation of favorable conditions for professional practice, e.g., the career plan. Therefore, the urgency for such planning as an essential element to the professionalism of teachers could be one condition for the permanence and the sense of belonging to the "teachers-researchers" group.

Among the teachers in the group, those who attend the regular meetings already discussed their career plans; linking it to the interests they have for working collectively. Some ideas related to this issue can be found in research on the *knowledge base*, such as Shulman's.

Recently, Shulman's work became one of the references studied collectively by "teachers-researchers" in an attempt to increase the rigor of their own assumptions. But what is the relevance of the author's ideas to the teachers' everyday work?

The answer to overcome the controversy and polemics on this subject, according to Borges (2004), can be found in the movement for professionalization and hence the practice as a *locus* of professional learning, questioning the entire teacher education processes which departs from those guidelines.

Another question arises regarding to this issue: Have the "teachers-researchers" shared some specific situations of their teaching work in common projects? And teachers who work both in institutions of Higher Education and Basic Education have initiatives that directly relate to the *locus* indicated by the author? There would be some system similar to mentoring between the teachers?

A frequent but less specific initiative was the simulation of teaching situations during the group meetings, in a system similar to educational workshops or teaching laboratories. To what point both initiatives have been valued by the teachers themselves as they reorganize their systematic meetings? There is emphasis in discussions of everyday experiences (which includes monitoring and other projects) or in situations with themes of education (which includes professional intervention, albeit simulated)?

EMPOWERED STUDENTS: WHAT DO WE KNOW ABOUT WHAT THEY KNOW?

The challenges for educational scientific research in the contemporary world has been reducing, as mentioned earlier in this text supported by Contreras Domingo (1994), the dissonance between what the reality reflects and what we wonder about it.

In Education, many "fields" are being placed literally face to face in an attempt to approximate the polysemic borders that characterize the professional practices that make up these fields. What fields are we talking about? The academic field, concerned to theorize reality through research; the field of public policy, concerned to justify and implement macroeconomic-structural actions; and the field of the teachers' work, concerned to justify their practices.

Historically, these fields co-exist; establish relations of power, values, and are both dependent and interdependent according to their needs. What we have seen in the comparison of these fields, implicitly, is the emergence of the need for demonstration of "other subjects" that make up these fields, such as the students. In our view, at this time, students as subjects constitute the field of teacher's work. And consequently we, as researchers, need to write questions and answers that have not been made yet in an approach that involves those subjects, in order to contribute to the understanding of the complexity that characterizes the constitution, existence and uniqueness of educational practices.

Campos (2009) in an attempt to answer the question *What is research in education useful for?*, refers to three difficulties confronted in Brazilian educational reality: i) past problems such as illiteracy and lack of access to education, and contemporary problems such as the recognition of ethnic and cultural diversity in order to provide students with skills in different contexts; ii) knowledge circulation, confronting conceptions

absorbed by the contemporary society, and the intellectual production (scrambled world views); and iii) propositional character of the production on education, marked by ideological positions and political games.

Charlot (2006) stands in the same direction about the specific challenges that permeate educational research, both in Brazil and in France, and probably in other countries, and points out the main issue: research studies have focused on education or on education? The author asks whether there is an educational research, specific, unique, or a set of research on psychological, sociological, and pedagogical characteristics dealing with education?

The author goes even further: There is an area of knowledge called education or that area is of policies and practices on which various social and human sciences produce knowledge?

The answers to such questions are, especially the last, essential for defining the research in education or on education, its specificity, its challenges, the links between knowledge, practices and policies. Charlot also raises three important issues that cannot be ignored in education: i) the views of academic professors and researchers; ii) the space of discourse and different characteristics; and iii) the uniqueness and originality of research in education.

The latter aspect is a concern of one Doctoral project in progress, which refers its intentions to investigate learning – knowledge – of students in a formal educational process.

The school failure, socioeconomic contexts, the quality of education and work, and preparation of teachers are examples of objects of research that never go out of fashion as highlighted by Campos (2009) and Charlot (2006). According to the authors, even though many of these aspects already had been analyzed in academic circles, what nevertheless still need to happen is critically analyze what kind of research on the reality has been done and what new questions have to come to exceed the already saturated speeches.

In Brazil, the data we have from the research of the decades between 1950 and 1970 present *bias*, e.g., theories of reproduction are still present in the conceptions of Basic Education teachers. Such teachers' belief is justified by the supposed decline in quality of public school education (Campos, 2009). We cannot forget that until the mid 1980s the access and permanence in Brazilian public education was restricted to a less significant portion of the population. This information enhances and substantiates the need for answers not made yet for complex phenomena rarely explored in essence. Dubet (*apud* Campos, 2009, p.276) observes that:

> All analysis situating the causes of students' difficulties in society and families are welcomed, they reinforce the image of the school as sanctuary; all those evoking causes located in the school running and teaching practices are neutralized. We need to get the sin out of the walls of the temple.

Campos (2009) points out that the answers about the complexities of educational research are relativized by those responsible for the research, who prefer legitimate the discourse diversity between the university and society, the relations between types of knowledge and the meaning that such knowledge assume to subjects situated in different spaces and professional contexts.

> This assertion urges us to clarify the possible contributions of PE as area of educational intervention, which has the school routine as traditional space situated by the complexities yet unexplored by the existing theoretical and methodological propositions, especially regarding relations with knowledge established between students and teachers. There are few studies that focus on knowledge produced by Brazilian students in PE, references that bring instigating aspects are the works of Schneider and Bueno (2005), Schneider, Kuhn, and Santos (2008).

The complexities of school everyday life *with* and *within* PE have been concerning authors like Bracht (2003), Betti (2009), Venâncio *et al.* (2010), and others seeking answers to their preoccupations through research with propositional methodologies such as action-research.

Venâncio's (2010) concern about the knowledge produced by students *with* and *within* PE classes had its problems raised from an organized educational practice supported by the principles of that methodological framework. The coauthor of this article could share throughout her educational intervention with other subjects – PE teachers and her Basic Education students – pedagogical and political issues that influenced changes in her practice.

This attitude has caused changes, generated knowledge, and allowed more space to make public the work with students in PE using different media.

During a period since 2005 to 2008, one teacher who calls herself a "teacher-researcher", systematized situations and experiences in PE classes with students from 6th to 9th grades, which intentions and meanings

constituted very singular manners. Some experiences have begun from common sense conceptions and gradually gained another dimension, values and mainly ways for conceiving the subjects.

The notion of relationship with knowledge by Charlot (2000, 2005), and the principles of dialogical and emancipatory educational practice advocated by Freire (2002), both approximated to Kunz's (2004, 2006) PE theoretical and methodological proposition that explicit concerns with the subject's movement, will be the main theoretical contributions for the research on students; along with other authors who argue about the epistemological and empirical research. Beforehand, it is assumed that an epistemological retreat will be necessary to understand more properly *where* the authors speak from, and whether they value the subject as object of investigation.

The concept of subject that is currently highlighted in the research is defended by Charlot (2000): a human being, open to a world that is not limited to the here and now, driven by his/her desires in relation to other human beings who are also subjects themselves; a social being, who grows up in a family (or something alike in substitution to a family) and occupies a position in a social space, who is included in social relations; an unique specimen of the human species, who has a history, interprets the world and gives meaning to that world, to his/her position in it, his/her relationships with others, his/her own history and uniqueness.

Further, according to the author, this subject: acts within and onto the world; finds out the question of knowledge as necessity for learning and like presence in the world of objects, people and places with knowledge; produces him/herself, and is produced through education.

At the moment the research is in the process of theoretical-methodological deepening, definition and characterization of the subjects that will compose the sample.

Given this assumption of *what* the subject is, for gathering information that will form the main body of analysis, we opted for focus groups. For Morgan and Krueger (1993), the research with focus group aims to capture, from the exchange of concepts, feelings, attitudes, beliefs, experiences and reactions carried out in the group. The focus group allows a multiplicity of views and emotional processes emergence by the interactive context created, allowing the collection of meanings that could be difficult to express with other techniques.

In our study on the students' perspective, the intention is that during the meetings students can talk openly and express their knowledge, forms of appropriation and understanding of what is to know, how and what they learned, their feelings, meanings about the relationship with knowledge within PE. The interaction that characterizes the collection of information in the focus groups is expected to capture the areas of conflict, contradictions and tensions in the students' speeches, which could help to empower them to analyze the information, and cause the distancing and approximation with the beliefs of the researcher who is also the teacher of such students.

It is noteworthy that semi-structured interviews will be used for collecting and analyzing data during and after the focus group meetings. We understand that they will be pronounced from one collective context. We are going to use as procedures the display of images (photos), videos, interviews and records of students and teacher made during and after classes, document analysis systematically organized and presented to the school collective and in other forums.

PRELIMINARY RESULTS AND NOTES FOR FURTHER INVESTIGATION

Preliminary results indicate that action-research is an appropriate method to support the teachers' work, concerning the quest for improving teaching quality and teacher autonomy. It features that teachers' life history is relevant to deepen contextualized critiques on their own work, and to consider the research as inherent in the teaching work.

It also points out the need to assume explicit commitment to meaningful learning in order to empower subjects to intervene in their own realities, and consolidation of collaborative partnerships between teachers-researchers who work with PE. Therefore, considering these aspects of our research, we believe that the educational process of the student-researcher also involves the permanent education and development of the teacher-researcher.

At the same time, the education seems to be a field saturated of answers, but perhaps without proper questions or problems to answer. According to Charlot (2006), education is a threefold process of: humanization, socialization, and cultural (uniqueness and subjectivity). One educates him/herself as a human being, member of a society and a culture, a singular subject.

Lave and Wenger (1991) argue that the situated learning views the phenomenon of learning as a process called legitimate peripheral participation, i.e., learners acquire knowledge and skills when they participate in the sociocultural practices of a community of professionals. The purpose of this approach is to explore the concrete relationships that exist among people, as a proposal for understanding the phenomenon of learning.

Based on that idea, the authors believe that learning is not only situated in practice, but it is an integral part of the widespread social practice in the lived world.

The authors also consider that in every community of practice there is a learning curriculum that considers the main sources of learning opportunities are found in everyday practices that learners experience.

333 - Older People Motivations and Interests in Learning Computers
A Grounded Theory Study

Luís Barata[1], Ana Barata[2], Mª João Moreira[3], and Eurico Lopes[4]

Abstract: In this work we seek to understand how older people see ICT and how they use computers as a mean of integration into society. The aim is to research what changes in terms of relational structures, especially in the way computers helps and approaches social networks of the elderly. The research focused on the experience of learning from students in USALBI, under Grounded Theory Methodology. The data was collected using observation and open interviews. As results, there is a clear division of groups, the result of individual interests, in particular: those wishing to acquire and expand their knowledge base in terms of information technologies and simultaneously demystify its use; those who want further integration, with the different social networks, particularly at the household level.
And those wishing to use Information Technology and Communication as a form of virtual approach to the various systems (family, friends ...).
This paper shows de work done under Grounded Theory Methodology to understand older people motivations and interests in learning computers.

Keywords: Social informatics; learning in old age, grounded theory methodology.

INTRODUCTION

The last five decades, in addition to all the great achievements of humanity, are marked by the achievement of life expectancy, the result of all the advances in medicine and social concern of how people get aged. Being the aging of the population one of the major challenges currently facing humanity (Foitaine, 2000; Fernandes, 2008; Nazareth, 2009).

Several organizations such as the United Nations, European Commission and World Health Organization reaffirm the need to look at how people age, given that every time there is a higher proportion of new vs. old and with the increasing of the technological society, there is a marginalization of older individuals.

With the high development of Information Technologies and Communication, and its relatively low cost, globalization of its use is increasing, being now part of everyday life. But this technology is geared for the modern man, which is not the standard of our society, given their heterogeneity, which creates people who feel excluded from such interaction with technology, and as a result the interaction with others.

This paper shows that the idea of old synonym for useless fades over time, and these *"new elders"* are quite participatory. Thus it was investigated that activity and participation in a University of Third Age, the Senior University of *Castelo Branco* (USALBI). Using the Grounded Theory Methodology (GTM) with open-observation and interviews the work analyzed the motivations that lead older people to learn computers, and seeks to unveil the underlying interests. Describing how elders see computers and information systems and how they see the use of computers to integrate them into society. This interpretation also includes changes observed in the level of relational structures, especially in the way the computer helps and approach social networks of the elderly.

This article is organized to give a general understanding of the study, starting a brief justification of the methodology, organization of study participants, data collection and ethical issues involved. Subsequent steps are described in GTM and lead to construction of categories and the framework. Finally discuss the results and presented the future work.

METHODOLOGY AND STUDY

The research methodologies can be classified as quantitative and qualitative, differentiated by their origin, while the quantitative methods generally use statistical methods to verify a particular hypothesis, and qualitative methods seek to understand the phenomena by explaining them through analysis.

Qualitative research, according to Flick (2002), is a research approach that produces results, without involving quantitative or statistical procedures. Thus, it can be defined as a process of interpretation, with the aim of discovering concepts and relationships in the data collected by organizing them into a theoretical scheme with a valid meaning.

For this reason, qualitative research methods are especially used in research that seek to understand the nature of human experience, in specific situations. These methods are also used in studies that seek to research areas of undeveloped knowledge, with the aim of creating new knowledge (Strauss & Corbin, 1990).

Since the study of the interaction of elders, with information technology and computers, is still an aspect slight studied and there is few documentation, it appears that qualitative research fit the scope of this study. We intend to research the experiences, interactions and practice with computers, complemented with a data analysis to generate new knowledge or theories about the subject.

Grounded Theory (GT)

The Grounded Theory has its origins in the context of sociological studies, despite being increasingly used in research on new technologies. It is characterized by constant development of the theory; through a recurring process that evolves naturally as the collection and data analysis occur simultaneously (Strauss & Corbin, 1990).

Grounded Theory has the purpose to build and do not verify the theory (Flick, 2002). Therefore, using this methodology, the researcher has essentially an interpretative role, introducing throughout the investigation, the views, ideas and sensitivities of participants.

This choice was due to the fact that the need for, first studying a social and human aspects, that involves people. Hence the choice of a qualitative research method, and secondly the need to create new knowledge, and understand a little explored area of knowledge, a factor that Grounded Theory is particularly appropriate. This methodology is based on the idea of researching, not having or using pre-conceived ideas; the researcher should begin to research with a clean mind in terms of aspects to research. In the process of analysis, this methodology is very time consuming, since it involves a repetition of processes: data collection, analysis, creation and validation of theories, restarting the process with new data collection in an iterative process of data assembly, creation new hypotheses, further reading and new iteration until saturation of categories.

For Strauss and Corbin (1990) at an early stage the researcher must select a group where it can see evidence of the phenomena studied, and methods used for data collection are observation, interviewing, documentation, audio recording, video recording or combinations of them. These decisions are based on what the researcher considers that best suits their objectives, and may at any time be adapted and redirected, if the development of the study so requires.

Fitness on the methodology of research

The selection of Grounded Theory proved adequate as a research method for this study, because it helped the development of a conceptual system in organizational improvisation, by leveraging the use of credible evidence, drawn from a complex context.

The possible range of data sources, setting up of their treatment, and the construction of narrative theory, are works which require as a condition, the compliance of the guidelines of its implementation. The use of Grounded Theory allows one to obtain conclusions, which are in harmony with the social reality and organizational sciences, giving clues about the behavioral aspects involved in the study.

The Grounded Theory is a research method, that doesn't start from a hypothesis or theory. A Grounded Theory-based research often starts from a bad structured problem, which is being continuously structured along the development of the research. It is therefore important that the researcher does not focus its research and has no preconceived ideas when collecting and analyzing data (Robinson *et al.*, 2004).

Participants

This research focused on students at the Senior University of *Castelo Branco* (USALBI), enrolled in the computer classes.

Table 1 - Distribution of Interviews

Level I	Level II	Level III	Teachers	Total	Men	Women
3	4	1	3	**11**	8	3

The students can be divided in three groups in what concerns the motivation to learn computing:

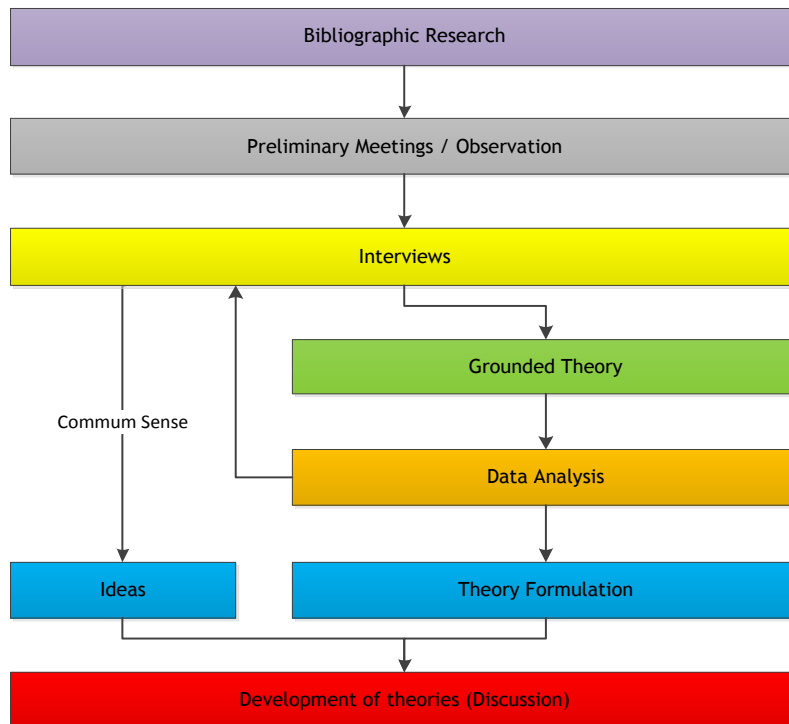
- Those who want to demystify the computer, they know what it is, know what it does, but do not know how it works.
- Those who want to understand their grandchildren and the world that surround them, not feeling completely apart of their reality.
- Those who use the Internet as a means of communication with the ones that they care and with grandchildren, who are distant, seeking in the Internet the ability to bring them closer.


Figure 1: Work Organization

The students interviewed are in an age range from 54 to 70 years and his academic background is quite diverse, some students attended school until the old 4th grade, while others have completed higher education courses. The same heterogeneity is true regarding to their occupation before retirement: businessmen, teachers, postmen or electricians.

Glaser and Strauss (1967) define this strategy as theoretical approach, which aims to *"representativeness of concepts"* rather than the representativeness of the sample. According to Strauss and Corbin (1990), a researcher initially choose sets of situations and people in the study area and follows the analysis using samples based on the concepts that emerge as most relevant. In this method, sampling and analysis, are processed almost simultaneously, being the sampling directed according to the results of the analysis.

Observations

Complementary observations were made of classes, with the aim of giving the start to the *"immersion in the study site"* (Janesick, 2000) and an adaptation of students to the researcher. This methodology was applied so the results to be found were developed as a product of this research, in fact, grounded in reality (Glaser & Strauss, 1967; Strauss & Corbin, 1990), thanks to the direct contact and interaction reality of students with computer's use.

The direct contact between the researcher and the students, in their daily environment, provides an observation *"in the natural context of occurrence, among the actors who would naturally be participating in the interaction, and follows the stream of everyday life."* (Adler & Adler, 1998:81), approaching the researcher with the reality of the facts.

Based on these assumptions, the process of class observation was made, so that does not create interference with the normal operation, seeking above all, to see how the students interacted with the computer and technical difficulties that were finding. The items collected were notes that were later used in forming the interpretation of the study results.

Interviews
Open interviews were used in order to know how the students interact with the computer, either in class or in their everyday. It was the most effective way to understand how they view the world of computers technology. The informality of the interviews along with the environment, which tried to be relaxed, allowed students to talk about their experiences, without any limitation or prejudice.

The interviews also approach the students to the research, making them feel that their opinions and ideas were central to the development of this work.

Interviews were open, so there was no set any interview guide, since its construction and follow-up, would influence the respondents to the ideas implicit in the questions or issues to be analyzed. Therefore, and to avoid pre-conceived ideas, the questions asked; only served to link the ideas and to explore some of the points raised..

Ethical and privacy issues
During the fieldwork, ethical principles, such as voluntary participation and confidentiality were a guarantee. Before each conversation and / or approach, the objectives of the research were explained to each individual. Participants were informed that their name or personal information would not be disclosed, been delivered to each one of them an Informed Consent Form, with the objectives of the work and the conditions of confidentiality of their participation.

In the interview process, none of the participants was pressed for an answer, having been informed that they could refuse to answer any questions. Situation that never occurred, since interviews were conversational, which made the participants very comfortable.

All interviews were conducted with the consent (and collaboration) of the institution (USALBI), having been given their approval, from the early meetings.

In classroom observation, before the start of each lesson, the teacher explained the reason for the presence of a person outside the group, a presence that was never challenged by any of the students (in fact was much appreciated).

To avoid disrupting the normal functioning of the institution, the interviews were recorded in days at hours that students did not have any kind of activity, and in their schedules wasn't made any kind of pressure for students to attend.

It was guaranteed the privacy of respondents, given the fact that in this work there isn't any information that identifies them. It was also mentioned that at any moment they could abandon the interview by withdrawing its consent and this wouldn't result in any kind of prejudice in his relationship with the researcher, or the institutions involved.

Analysis with grounded theory
The Grounded Theory Method was followed to develop a grounded theory that explains the orlder people motivations and interests in learning computers. Next follows a description of the theoretical procedures that were adopted during data collection and analysis.

Highlight of Important Ideas
Based on the transcript, we proceeded to multiple readings, emphasizing in each the most important aspects relevant to the research. This analysis allowed the identification of some common points between the experiments and experiences with the computer by the students.

To represent the importance of these ideas they have been marked by highlighting the text.

Figure 2: Sample Annotated Transcript

In order to group the ideas of the first set of interviews, the main ideas were organized into small *"Post-it's"* in an easily way to organize them by concepts, and then join the common ideas of the various interviews.

Figure 3: Main Ideas of the Student Interview

Grouping of common ideas

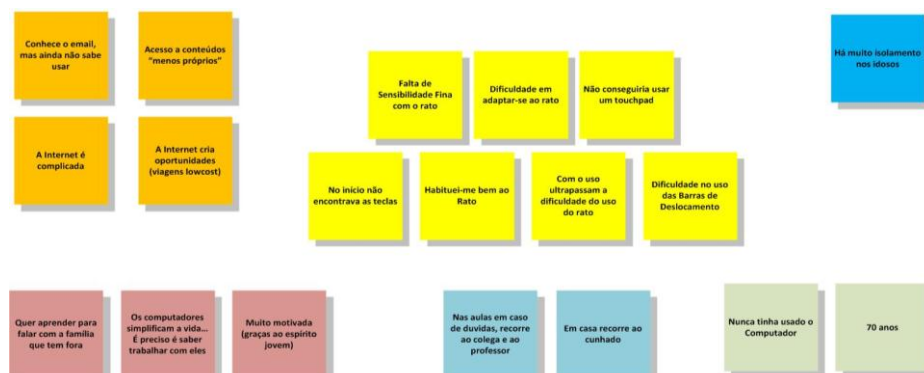
The most important ideas were organized at the end of the analysis of individual interviews and several concepts could be grouped.


Figure 4: Grouping of Ideas from Interview

Coding of Interview (Key Concepts)

In parallel, in order to verify the main ideas of each interview, it was conducted an individual encoding, using the method of Coding Key Concepts, which, as regards Rodrigues *et al*. (2004), allowing meaningful concepts arise from the transcripts.

Figure 4: Coding Student Interview

After this review process was an elaborate coding table, containing all the key concepts found in all the interviews (Rodrigues *et al*., 2004).

Figure 5: Table of Keywords obtain from Coding

The data in this table were crossed with the analysis made to each of the interviews, seeking ideas, aspects and common items.

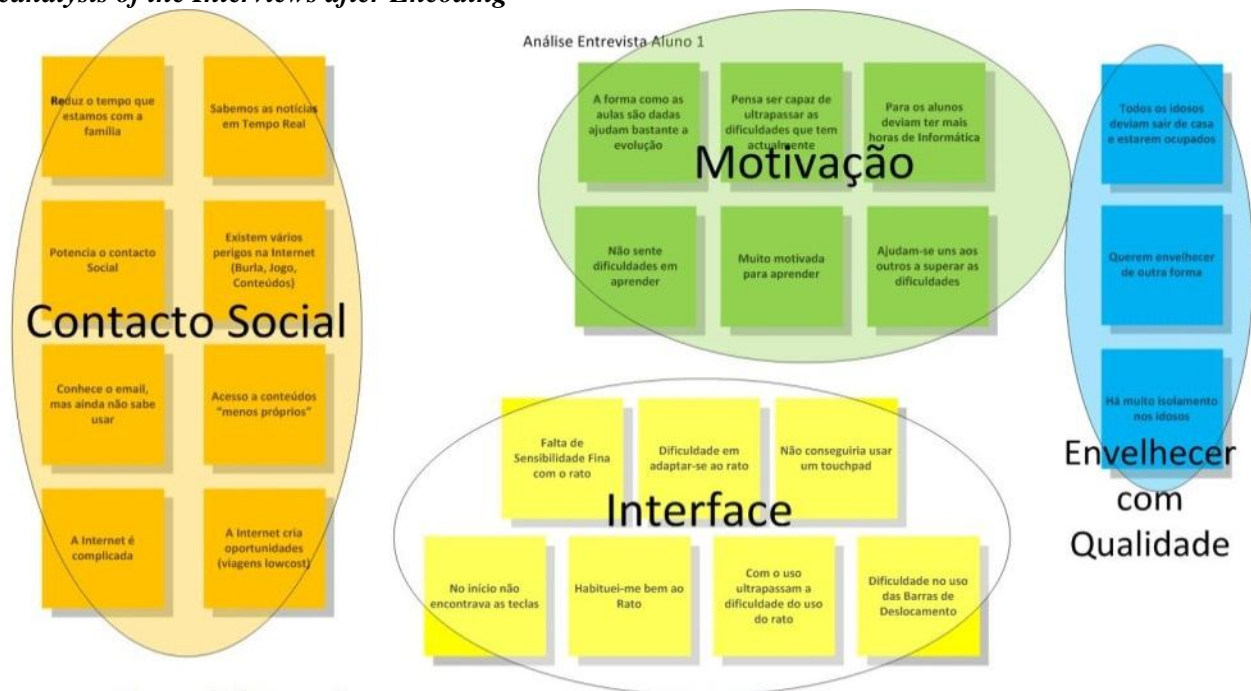
Reanalysis of the Interviews after Encoding


Figure 6: Review of the first interview after the process of encoding

Interviews reviewing process allowed the validation of the initial analysis grouping of ideas, which together with the data by coding the key concepts were the basis for the formulation of theories from this work.

Elders and computers: the grounded theory
The analysis revealed eight categories, each of which is the result of the grouping and combination of several key concepts, resulting from the coding of all interviews. These are:

Communication
The communication category includes all the concepts related to computer use and ICT's as a way of keeping in touch with family and society outside.
The computer is viewed as a form of communication and interaction with others which helps in the process of fighting the loneliness which increasingly takes place in the elderly. Not only in being able to communicate from home, but also by having to leave their residence to attend classes, thus allowing insertion of a person in a group of peers.
Students use the Internet and electronic mail to exchange information with distant relatives in a way that allows them to track their life, creating a kind of virtual or digital presence.

Information
It appears that the older use the computer and the Internet as a way of keeping up to date, about various subjects, they are the ones that make the selection of what they read or access. Being the information focused on their needs and sensitivities, this is for them an advantage because they do not have to be guided by any editorial policy of a newspaper or TV newscast.
Accessing information and the beginning of any internet browser interaction, generally starts from Google. Students find the simplicity of Google an advantage in the process of finding information, combined with the fact that they can quickly find the information they want.

Learning
Above all the students want to master a given task with the computer. It can be verified that besides the need to learn to use the internet as a mean of communication, they also feel the need to be updated, in order to understand the experiences and their grandchildren.
This category gathers all the concepts about how the older capture the knowledge of IT, and how this knowledge they are transmitted.

Motivation

This category represents the will and commitment that all individuals demonstrate on learning computers, which is essential in the ability to acquire knowledge and concepts about the interaction with computers. The motivation is the factor that triggers the need to learn more about technological artifacts. The need of being socially active (social contact) and the need to understand the world of their grandchildren is the factor that approach elders to the new technologies and mainly the Internet as a way to communicate with the ones that they care and as a way to overcome the distance between them.

Digital Inclusion

Digital inclusion promotes the ability to think, produce and share knowledge with the society. Being the main reason why elders are interested in learning computers. The fact that they feel overcome creates a certain discomfort, making then feel a bit apart from the society that surrounds them.

There is a change of roles especially in the way that they interact with their grandchildren and technology; there is an inversion on role of the teacher (the transmitter of knowledge) and the student (the receiver of knowledge). The role on the teacher that was given to the elders, because of their life experience, is now given to the grandchildren as they teach and help their ancestors to work with computers and deal with technology.

Simplification

Simplification is a concept found in the coding of all interviews. For the students the idea of the computer to simplify their everyday is an acquired truth. Also refer to the fact that more and more services become available over the Internet.

Social Interaction and Contact

This item represents communication, contact and relationship with those around them.

Social contact is an important aspect with regard on aging in these days. Using computers and the Internet it is the way to combat social loneliness.

Represents the need to live in society and not fall into the scourge of loneliness, which is seen by everyone with a huge fear.

Fear

This category represents two ways of fear that afflict the elderly in interaction with computers. The first relates to the fear of using the computer, which is one of the factors inhibiting the use of technologies. The second shows the fear of information accessed from the computer, mainly from the internet and widespread in the mail.

Elderly and computers: gtm framework

This framework describes the relationships between the categories obtained. In the epicenter are the elder people that as we have seen, have the need to feel integrated into society, trying to overcome the problem of loneliness in the elderly.

The need for social contact and interaction generates the motivation to upgrade their skills and knowledge and to be part of the Digital Society. Allowing elder not to feel outdated will improve their self-esteem, and by other hand will allow a better relationship with those around him, especially his grandchildren, who are already more advanced technologically, allowing an easy approach to them.

These factors make older people feel the need to dedicate themselves to the technology and computers learning, trying to develop the abilities to communicate, using the computer as a form of communication. This is also a way to access information (knowledge) of various levels, news services, new knowledge or contents to simplify their day-to-day.
Diagram 1: Framework derived from the GT analysis

Communication is based in Internet access, which is the main reason that takes students to learn computer's, as they see the internet as a way of communicating with those around him. Communication can also be seen as a way of being socially active, and as a form to transmitting the knowledge acquired throughout the life.

The simplification is mentioned by all respondents, whether as a result of the application of computing on the day-to-day, either as a necessity, being defined as a key category for the development of emerging theories. For the same reasons fear was also considered a key category, by the fact that many students often refer concerns about access to information, especially online, with access to communication tools such as web or email.

DISCUSSION

Difficulties in the use of Computers
It appears that initially, the greatest difficulty for students who have never had contact with computers is fine dexterity. This is the first barrier they have to overcome, especially in the use of the mouse.

Interestingly, about half the students do not report the mouse as being a problem, just report difficulties at an early stage of its use. Therefore we can say that over time the mouse is no longer a barrier and not an obstacle for seniors to use the computer.

The field work supports the idea that the use of computer resources is a benefit from a biological standpoint, since the computer enhances the stimulation of reasoning and memory, while also allowing greater flexibility in their hands, thanks to training that is done to muscles.

By participating in class, students battle the scourge of loneliness, a subject that is so awake and present in our consciousness, motivated by more recent experiences of loneliness in elderly people.

All this learning process leads to the use of ICT as a way of socialization, and a way to integrate individuals in active society through the use of the Internet. The use of the computer and the Internet encourage the reading, the thought and the concentration on what they read, thus promoting the interaction with day-by-day events.

Fear of the Use of Information and Communication
Access to information and communication generate in elders fear factors that should be fought. The technophobia (fear of modern technology), was easily incorporated into the list of stereotypes associated with older people. The basis of this new stereotype is based on the belief that older people are adverse to new

technologies, in a conscious and deliberate way, and not as the result of the historical path and constraints that have dictated its info exclusion.

There are a number of difficulties that reduce the success that elders have in the learning of information technology:

- They hesitate initially, with fear of damaging the machine;
- Lack of expertise, as the result of the decrease in motor skills;
- Fear of making mistakes;
- Fear of failing to learn a new thing.

Besides the fear in using computers, there is the fear of the Internet. Students have the idea that Internet is a source of fraud, and they are the ideal targets, so all activities made online, are made with great fear.

This fear is due to the fact that the Internet is a concept that is not visible, has no face: students do not know who is on the other side of a site or an e-mail. This lack of personification makes the breaking of the trust relation, a situation that is very important to them.

Simplification of Information and Communication

Another major challenge that arises is how to teach elders in the use of computers. How can the way that a technologically complex machine works, being explained to someone that during his life experience had no contact with information technology?

The students reported a great difficulty in perceiving everything that surrounds the computer technology. Each one, on its relationship with the computer, is building a way of thinking and interacting with the machine, which is the result of a process of growth of knowledge over time. The individual ends up forming his own awareness of computer technology, creating mental processes that allow them to perform actions and interact with the computer.

The major difficulty in the learning process is the fact that, teachers need to forget the mental processes that we created, and try to create them in conjunction with the student. It should also adapt the contents to cover the student's needs. A student at an early stage of their learning needs to demystify the computer, not giving much explanation about hardware or software.

This whole process of learning and demystification is very important, since it depends on the creation or elimination of phobias. In the same way that learning in old age must follow several rules; also the learning of computers must follow these rules. It's important to realize that each person has their own learning pace, so the transmission of knowledge must accompany the student's needs, and not just any hard lesson plan. It was also mentioned the need for more hours per week in order to enhance learning, thus creating more training days and time with the computer.

Also the amount of information that appears on screen is a difficulty for students, so it is important to explain how the information is divided on the screen, and how we interact with that view. It is therefore important to simplify the way it communicates and accesses information. Therefore, there is an urgent need to simplify the use of computers and information technology.

The simplification of computers usage, could assume the development of physical interfaces adapted. This has not occurred in the observation of the target studied; there was rather a need to simplify the process of interaction. For them, the need is not to create adapted interfaces (voice commands, no mouse, minimalist interfaces, among others), but the need to adapt existing ones so that they can use the computer as a tool, which enables the simplification of day-to-day tasks.

FUTURE WORK

This study is a beginning to research the relation between computers and elderly people. Extend the study to other kind of population, research elderly people with less education, since most studies related to aging and technology is associated with older and younger people with more years of study. Future work must also identify applications that elders are more susceptibly to use. Complementary research must also be done in the study information technology curricula building a virtual environment for study and self-study, to allow the response to several questions that students may have, without a teacher around.

tpessoa@fpce.uc.pt

Abstract: MediaIntertalking is an experience of exchange and collaboration between the University of Salamanca (Spain) and the University of Coimbra (Portugal). The goal was to create a tool, in this case an edu-blog, from which students from two universities could create and mobilize debates about the mass media, according to the different topics and subjects involved (Education and Media -University of Salamanca, and Technologies in Education, University of Coimbra). This paper describes, firstly, how the site was pedagogically designed, the sections and their objectives. Secondly, the paper presents preliminary results from the initial exchanges generated, which are analyzed by quantitative criteria and a qualitative evaluation among students by a final survey. Conclusion from these results are serving to feed back the new debates and activities initiated within this new academic course.

Keywords: Higher education, Blog, Forum, Media Literacy.

INTRODUCTION: A CONTEXT FOR EXCHANGE AND PROMOTING PARTICIPATION

In recent years, the context emerged under the European Higher Education promotes the opportunity for encouraging the teachers' clustering in related subjects, aiming at enriching exchanges that contribute to the visibility and comparability of teaching and learning spaces.

In fact, the higher education system has adapted and reacted to various changes associated with the construction of the European Community and, in particular the Bologna Declaration (1999), the Prague Communiqué (2001) the Berlin Communiqué (2003), the Bergen Communiqué (2005), the London Communiqué (2007), the Leuven / Louvain-la-Neuve Communiqué (2009), and has travelled a long way toward building a high-quality European higher education system.

University teaching responds to all these challenges. It is a fact that profound changes have taken place with the beginning of the Bologna process. These changes have implications for the epistemological concepts that underlie the design of the courses, that is, in our teaching and learning practices. This is a process that manifests itself on teacher's and student's work and culture in a variety of different ways.

In terms of ideas or intentions we can say that we have changed from an essentially transmissive pedagogy towards constructivist pedagogy. The major change affects to the educational paradigm in which the emphasis moves away from teaching to focus on learning. Now what is really important is the quantity and quality of learning acquired by students, not just the teaching process (Vaz-Rebelo, Pessoa, Barreira, 2010)

We've changed from a teacher –centered to a student-centered pedagogy based on the student's work and his independent and self-regulated processes of learning. It's now recognized that the construction of knowledge is based on the individual subject's experience of reality and the value that she can ascribe to it.

The construction and development of knowledge by the students is based, then, on an inter-subjective truth or standard of viability (*norme de faisabilité*) that ensures the value of knowledge or of the subject-world relationship (Le Moigne, 1999.68).

Under this constructivist epistemology, the teaching-learning process does not fit the simplification and compartmentalization of knowledge that underlie an objectivist conception of it.

The learning process is rather a shared path that is supported in real contexts and significant situations, which can be addressed and commented on by explanatory theories and models. The aim for students is not only to acquire a particular content, but also appreciate, understand and know-how to use information along with the ability to think and solve problems that arise in real contexts.

Teachers have no longer a central role in the educational process; no longer a primary source of knowledge, nor the main agent of transmission of knowledge. Among the reasons are the current easier access to information, guaranteed by the Information and Communication Technologies (ICT).

Besides, teacher today performs many other functions apart from teaching. In the case of the university teachers they do research, designs projects and partnerships, in combination to the proposals for the

778

development and collaborations with other national and international institutions, as high relevant tasks towards the transferability proposed within the European Education Area (Zabalza, 2007; Lopes, Vaz-Rebelo, Pessoa, 2010, Vaz-Rebelo, Pessoa & Barreira, 2010).

For the student, changes are also appreciables. Students assume the main role in the educational process; they are the main actors in the development of their own learning. Thus, learning is conceived, more and more, as a process of development, construction of knowledge, processes that are intended to develop autonomy and self-regulation.

The biggest concern brought with those changes is the development of a critical thinking. The development of skills necessary to be a critical and reflective citizen of the 21st century presupposes innovative pedagogical approaches. Learning to think critically and reflectively in higher education - both on complex and poorly-structured fields- requires ways of teaching and learning that are often the antithesis of those used in simpler domains: contextualized learning, multiple representations of knowledge, and presentation of information in a network (Spiro et al. 1988, Spiro &, Jehng 1990).

Nowadays the training process is intended to be participatory, transdisciplinary and European. In fact the declaration of Bologna has launched a process commonly known as the Bologna process, which aims for the student to design their training with internal and external mobility. With this end a general system of credits and European - the ECTS (European Credit Transfer System) - was launched with the primary goal of developing a set of procedures that would be comparable, and thus allow equivalences between different academic courses undertaken by students in different European institutions.

This system of credits (ECTS) are "a key element of the Bologna Framework for Qualifications, compatible with the European Qualifications Framework for lifelong learning (EQF)"(Education & Culture DG, 2009, 9).

Emphasis is placed, as mentioned, on student performance. In fact the "ECTS credits are based on the workload students need in order to achieve expected learning outcomes. Learning outcomes describe what a learner is expected to know, understand and be able to do after successful completion of a process of learning. They relate to level descriptors in national and European qualifications frameworks." (Education & Culture DG, 2009, 11).

The student's work can be diverse, consisting of "as lectures, seminars, projects, practical work, self-study and examinations" (Education & Culture DG, 2009, 11), that is, work necessary to " to achieve the expected learning outcomes" which usually translates as follows "60 ECTS credits are attached to the workload of a fulltime year of formal learning (academic year) and the associated learning outcomes. In most cases, student workload ranges from 1,500 to 1,800 hours for an academic year, whereby one credit corresponds to 25 to 30 hours of work." (Education & Culture DG, 2009,11).

The ECTS system is a tool that promotes transparency fosters relationships between institutions and improves student choices.

This system allows the mobility of students and the student work can be achieved in different ways. Thus, this paper is based on an experience of exchange between two universities, facilitating the transferability in terms of practices (based on the new credit system) and in terms of knowledge (sharing and socializing by the Internet).

In this experience, the development of the European higher education area is understood as fundamental construction of knowledge in a collaborative setting, at a European level, facilitated by the use of ITC. This type of experience has been promoted through several actions in parallel, as follows:

- The establishment of other partnerships such as the "Arrangement of international university cooperation in teaching, research and management between the University of Salamanca and the University of Coimbra" conducted in 2008. Under this arrangement are placed annually in competition programs that make it feasible to support the award of double degrees, programs to support research and programs to support the mobility of teachers. In fact with this arrangement it is now possible for students to carry out their training with greater mobility and achieve an undergraduate degree or masters by attending the two universities. It is also possible for doctoral students to develop their research accompanied by scientists and researchers from two universities. Teachers may also have greater mobility and, under this arrangement, may perform research programs or visits or teaching programs.

- The mobility of teachers themselves, as happens under various other programs including Erasmus, could be an important step in building research networks at European level, international project

development, and the design of pedagogical approaches that integrate contextual knowledge in different situations.

- The areas of educational technology and media education, at the European level, require study and research that can help build disciplines that are consistent, reasoned and capable of equivalence at the European level

- The value added, today, by information and communication technology (ICT), and very particularly the Web 2.0, represents in terms of teaching and learning. This is a real revolution in terms of writing, living and thinking about the world. On the other hand it offers the possibility of creating real communities of learning and practice. These communities created through social networks, in non-formal and informal ways, need to be integrated in the context of formal learning.

As Redeccker et al (2009) state, the teaching-learning process based on Web 2.0 is a "emergent phenomenon, fostered by bottom-up take up of social computing in educational contexts" (p.9), which has had significant impact on training and education. Among the most significant uses that are stressed, following Redeccker et al (2009) are: facilitating access to information, that is:

- "**Opening up to *Society*:** Many educational institutions appropriate social computing as a means of facilitating access to information" (p.9);

- Promoting multiculturalism and a wide variety of audiences "**Embracing Diversity:** In a number of cases, social computing applications are used as a means of integrating learning into a wider community, reaching out to virtually meet people from other age-groups and sociocultural backgrounds" (p.9);

- Enabling students to communicate with experts from around the world "Learning 2.0 enables students to broaden their horizons, and collaborate across borders" (p.9);

- Encouraging the establishment and development of networks, communities of learning and different practices, that is " **Networking*:* In many cases, social computing applications are primarily conceived of as communication tools among students or teachers and between students and teachers. The examples studied demonstrate that social networking tools may: (1) support the exchange of knowledge and material; (2) facilitate community building, providing teachers and learners with social environments that offer assistance and (emotional) support; and (3) provide platforms for collaboration, allowing teachers and learners to jointly develop (educational) content" (p.9);

- Contributing to academic success " **Achieving*:* Learning 2.0 approaches can be used as a means to increase academic achievement. Social computing supplies learners and teachers with a wide variety of didactical and methodological tools that can be fitted to their respective learning objectives and individual needs with a positive effect on their performance and achievement" (p.9).

In general, as have been mentioned by these authors, it is possible to assert that they contribute significantly to learning "**Learning*:* In many cases, social computing tools are used to implement pedagogical strategies intended to support, facilitate, enhance and improve learning processes"(Redeccker et al., 2009, p.9).
Blogs, a web 2.0 tool per excellence, constitute a privileged tool for learning, learning to think, and learning in critical, reflective and participatory; specially those which aim is based on academic goals, named Edublogs. Considered as a powerful tool, we present an experience of exchange and collaboration between two Universities of different countries and languages based on the students exchanges throughout an academic Blog.

BULDING THE EDU-BLOG: DESIGNING AND STAGES
In the process of designing the learning community by means of the edu-blog it was considered both, the training of the students on the use of the blog and the planning of their activity. During two months the activities where displayed along six stages (see table 1).

Table 1: Stages of the project and duration

	STAGE	DURATION	OBJECTIVES Y ACTIVITIES
0	Creating the Blog: MediaIntertalking	1 week	Designing, objectives and sections Creation through Blogger Registration by the administrators (teachers)
1	Training (in the two universities)	1 week	Workshop Objective: basic notions and practices to familiarize students with the virtual environment (Blog)
2	Socialization Knowledge between students	1 week	Updating user profiles, facilitating exchanges among participants. Activity in the "Agora" (building community identity).
3	Initiation Activity	1 week	Once students are familiar with the online environment, they are asked to respond a inicitial practice (Describing two uses of blogs in an educational context)
4	Interaction and Discussion Micro-forum	2 weeks	Building and sharing knowledge. Methodology: three types of exchanges
5	Interaction and Discussion Global Forum	1 week	Building and sharing knowledge Methodology: answer questions drawn from the micro-forums
6	Evaluation	1 weeks	Assessment of interactions, knowledge exchanges (internal, external)

After the design and creation of the sections in the blog (Stage 0, http://mediaintertalking.blogspot.com), students from the tow universities were trained (Stage 2) by a specific workshop in which they can learn to manage with the online site (the blog). Then, two activities were provided for facilitating interactions. The former (Stage 3), for introducing themselves in the section "Ágora", specifying academic and personal interest; the latter (Stage 4), for initiating them in the use of the blog: publishing logs, adding comments, responding comments, embedding different media, etc.

According to Salmon (2004), they were provided with the opportunity for online socialization during the first weeks, with activities for motivation and community identity building. As well, the section "eTutor" was created for informing the students and providing them with the required technical support.

Discussing activity (Stages 5 and 6) on the edu-blog was planed following a methodology that evolves in complexity and support, where the facilitators play different roles in the discussions (Wang, 2008).

As the goal of this paper is focus on testing the effect of different methodologies for discussion on a blog, first, after teachers analyzed the socialization activity in the Ágora, three homogeneous groups were created (all of them having the same number of students from each university). Each of these groups conform a MICRO-FORUM for discussing around the topic of media literacy, as all students were previously assigned the same reading about "media literacy" (text chosen was González & Muñoz, 2002).

Discussions among the micro-forums were strategically planned, according to the hypothesis, and involved three types of methodologies:

- *Self-generated:* no intervention from the teachers. Students discuss freely on the chosen item.
- *Combined*: teachers and students made questions and answer them.
- *External-directed*: teachers provide questions, and introduce answers for encouraging the participation of all members of the micro-forum.

These three methodologies were randomly assigned to the different groups, so that each micro-forum has only one methodology, without students know this procedure.

The final phase of the study was a GLOBAL-FORUM, which debate consists on discussing the entire group of students, based on the questions and reflections provided by a delegate of each micro-forum (a student elected within the groups), who summarized and concluded on their own debate and prepare some reflective questions to discuss globally.

STUDY: ¿AN INTERNATIONAL FORUM FOR LEARNING IS POSSIBLE?

The experience involved a total of 51 students, 25 students from the University of Salamanca (male=4 and female=21) and 26 from the University of Coimbra (male=3 and female=23), in the same academic level, the last year of their Degree in Educational Studies.

The purpose of this study was to examine the impact of different methodologies in online forum discussion by the analysis of the exchanges in an edu-blog, considered it as an international learning community with students of different universities. The study was framed by two research questions:

- Are there any differences between the answers/questions in the three micro-forums, regarding the diversity of methodologies?
- To what extent does the use of different languages implies an obstacle of communication?

Method

Students' comments on the Blog were analyzed by applying a table of categories (see Table 2), according to other instruments used in previously studies (Bradley, Thom, Hayles & Hay, 2008; Wang, 2008).

Table 2: Categories for the analysis of the Blog comments (adapted from: Bradley, Thom, Hayles & Hay, 2008; Wang, 2008)

Type of answer	Type of question
1. Limited focal (narrowing to the topic)	1. Initiating questions
2. Open focal (open-ended, widening discussion)	2. Asking for opinion
3. Application (examples, references)	3. Suggesting to make connections
4. High order thinking (reflection, connection)	4. Inviting to analyze the topic in depth

According to Newman (2003) coding of the raw textual data were carried out in two simultaneous activities: data reduction into relevant parts and analytic categorization of the data into themes. Data was revised in two occasions, first, an axial coding (focus on the initial coded themes, reviewing categories, dividing in sub-dimensions, searching for linkages between concepts) and second, a selective coding (scanning data and previous codes, making comparisons and contrasts between subjects).

After the first codification by the researchers, a group of five experts from the University of Salamanca and the University of Coimbra, not involved in the experienced, contrasted a sample of the data in order to validate the frequency of categories obtained. The group of experts used the same processes according to the two phases for categorization described above. It was obtained a 93% of matches in between the coding of experts and researchers.

Quantitative measures (such as word count and number of comments) were taken during the procedure. As well, a qualitative evaluation among students was performed in the two universities by a final survey; together with the gather of informal commentaries of students during the process, or made via the Blog, in which they have been expressed the (dis)satisfaction with the activity, and the learning gains.

Results and discussion

Quantitative data regarding type of participation in the different forums was analyzed by the number of comments, their length (word count) and the type of answers/questions of students, by the categorization presented in Table 2.

In relation to the number of comments (Forum 1=49; Forum 2=58; Forum 3=62; Global Forum=103), no significant differences were found, however results indicated that students were more engaged in the Forum 2 and 3, where participation was semi or completely directed by the teachers.

The length of the comments was analyzed (see Figure 1) to determine the participation in the different forums. The Forum 1 was the one whit the comments shorter; opposite to the Forum 2. It is noticeable that in the Global Forum the comments, on average, where the shortest, due to although some students sent long comments, they are the lesser, observing that in this forum the students were more precise and concrete, focus-oriented. Regardless the personal style of communication, this data can be interpreted as a measure of experience, as all the students participated first in a micro-forum and then, in the global forum they probably have acquired some media literacy skills to participate in a forum on the Blog.
Figure 1: Word count in the comments of different forums.

Concerning the type of answer, descriptive data presented in table 3 indicates that the more frequently answers were the type 1 (limited focal). It is observed a slightly decrease in the categories, where the least common are the higher. Interestingly, in the Forum 3, which where directed by the teachers, and the Global Forum; in the first case, it is possible that the teacher would have encouraged students to progressively adapt their comments to higher order thinking. In the second case, as this forum took place after the micro-forums, and all the students would have the possibility to discuss previously around the same topic, it is probable that in this final forum, global, they were involved in a different level or higher.

Table 3: Participation in the Blog by type of answer/questions (in percentages)

		Forum 1	Forum 2	Forum 3	Global
Type of answer	1. Limited focal	66.6%	64.3%	59.8%	35.1%
	2. Open focal	19.6%	1.7%	14.6%	26.8%
	3. Application	14.7%	35.3%	37.9%	37.3%
	4. High order thinking	-	-	3.9%	7.8%
Type of question	1. Initiating	40.7%	40.3%	1,7%	8%
	2. Asking for opinion	59.3%	28.9%	35%	46.1%
	3. Suggest to make connections	-	9.8%	38.3%	11.3%
	4. Inviting to analyze in depth	-	8.3%	6.4%	45.4%

Regarding the type of questions, in the Forum 1, in which students generated by themselves the discussion topics, it was only observed the types one and two. In the Forum 2, where the questions where generated both, by the instructors and the students, the majority of questions were, again, the ones related with the initiation of a discussion topic, and the ones asking for opinion. In the Forum 3, the most frequently questions were the type three, asking for opinion:

> *"Y siguiendo el modelo de Aparici (1996), se interpretan 3: como espejos de la realidad, como ventanas al mundo y el último como construcciones de la realidad. Y de ahí la aparición de mi pregunta, a la cual me gustaría que contestarais para solventar mis inquietudes. ¿Hasta qué punto los medios de comunicación pueden ser constructores de la realidad? Pues como bien sabemos todas las informaciones se mediatizan por los códigos de representación de cada medio y son sesgadas. ¿Cómo elegir el adecuado?"* (female, USalamanca)

The Forum 3, overall, was characterized by the type of questions suggesting to make connections with other authors, or the professional future:

> *"Assim, como refere o texto é indispensável educar os meios, não apenas instruindo no que respeita a conhecimentos e habilidades necessárias à sua utilização, mas essencialmente tendo em conta a necessidade de se desenvolverem valores e atitudes face às tecnologias que permitam ao aluno, evitar cair numa fobia tecnológica, ou numa posição submissa perante as mesmas. Como defende*

783

Manuel Area Moreira uma das metas educativas deve ser a formação com vista a tornar os utilizadores das novas tecnologias críticos, conscientes e activos." (female, UCoimbra)

"Ahí es donde entramos nosotros, que somos los que tenemos esa función de educar, de formar a personas críticas ante los medios, objetivas ante la información que reciben. Como pedagogos debemos utilizar todos esos aspectos positivos que podemos obtener de los medios, esa creatividad y esa carga emocional tan ausente en las escuelas y que tan bien saben manejar los medios para captar a sus destinatarios…" (male, USalamanca)

In less percentage in the microforums, but higher in the global forum, questions referred to inviting to analyze in depth were found:

"Penso que o que referi são alguns bons exemplos dos benefícios e possibilidades que as novas tecnologias nos podem trazer. É claro que como em tudo na vida existe o lado negativo, mas cabe a todos nós, trabalhar no sentido de atenuar o lado negativo e tirar o máximo proveito do positivo." (female, UCoimbra)

Finally, in the last week, students were asked for filling a questionnaire (5 pints liker type) regarding the valuation of the experience. As depicted in Figure 2, responses were classified in between their participation in the micro-forums and globally.

Regarding the satisfaction with the activity, all the students, in both universities were agreed to confirm the experience as "very satisfactory". It is noteworthy having found that the students participating in the Forum 1 showed less level of satisfaction and the students in Forum 2 and 3, where the presence of the instructors were more visibly. A possible explanation is that students are more satisfying if they feel the teacher is partially or totally involved in the activity, finding it more motivating to participate. They manifested, also, that they felt more engaged if the questions were generated by the teachers, which they consider more experienced on the topic with, probably, comments more inspiring.

The question relating to "sense of social closeness" investigated around the perception of emotional involvement and the sense of having created a positive social context. They manifested as perceiving a high level of social closeness after the experience. As an example, some students continuing to use the section "Ágora" for expressing their personal opinions and even to the possibility of a project a face-to-face exchange between the two universities. Evidence of this involvement is that students follow to be connected to the EduBlog, even when the experience ended, and they were at their countries, as it is showed in the track back history (see Figure 3).

Those positive results were more evidenced in the item "repeating the experience", where almost all the students expressed their disposition to participate in the future in a similar experience.

When they were asked about problems, they did not find any difficulty regarding the differences in language. They found other technical problems (log-in, browser), as one of the days for participating in the micro-forums they could not access by external problems of the provider, and they were provided with the opportunity to participate via the main page.
Figure 2: Final evaluation

Figure 3: Track Back history of the Blog by countries

This final evaluation with the students showed a number of potentialities and limitations, which have been considered in the re-design of the activity for this new academic year. In brief, data have revealed significant learning results for the students of the two universities, who interacted and discussed successfully on the edu-blog, regardless the language differences. The groups in which the trainers provided more support were the ones the students felt they more involved and satisfaction with the activity. On the opposite, the groups where the discussion topics must have planned by the group members were the ones they considered having less satisfactory, expressing they had have more problems regarding the difficulties of getting a consensus online.

CONCLUSIONS

Students are frequently using communication technologies, such as Blogs or other social media, for personal aims. When this tools are used in academic contexts is estimated that the community skills learned in a non-educational context are transferred to learning in educational contexts (Conole, 2006), albeit, as Trinder et al. (2008) pointed out, there are inhibiting factors for transference, mainly based on expectations. Students are used to the paradigm of the instructor as teacher from whom they expect a great deal of input. However, it is important to clarify the changing roles within a context of collaboration, with great expectations on learner self-direction and mutual commitments.

Thus, in order to promote effective social interactions, online teacher needs to cope with several functions for promoting sociability (Hernández & González, 2011) regarding the perceptions that students could experience in virtual environments. Among the most important functions are:

- Promoting perception of presence in the virtual space. In this regard, online teacher has to establish an online identity as teacher and facilitate students built their own. This is the first step to create an atmosphere of cooperation.
- Guiding students from the passive spectator to the active participant. Fundamental for the online teacher is to engage the students and to trigger their participation, as well as their maintenance by providing them with appropriate feedback.
- Facilitating the immersion of the students by increasing the level of participation, and by using virtual spaces they know before. Online teacher may turn their frequently technologies, used for personal purposes, into academic tools for learning and socializing with other students.
- Creating a sense of social closeness. Loosing of visual clues in communications through virtual environments requires reinforce participation and a guarantee of adaptation by means of a design that resembles them a known spatial metaphor.

358 - Schools - The Art of Weaving Networks in Education

Rosa Helena Nogueira

Institute of Education, University of Lisbon
rhnogueira@ie.ul.pt

Abstract: This interpretative research is based on phenomenology, ethnography and grounded theory. It is focused on the educational activity and the relationships among actors in four Portuguese schools. The networks of relationships in schools and in the social context where they are integrated, expand the field of action along with the different social actors. New answers are emerging to face the complexity of current demands. New organizational concepts allow for participatory management. An innovative, reflexive and creative practice aims to implement concrete actions promoting interdependence, reciprocity, cooperation, participation, exchange of experiences, collective and shared efforts, exchange between different education systems and other organizations to promote events for learning; and reflexive thinking on educational issues, which is part of knowledge construction. This is a challenge to be embraced in the community, to weave networks in education.

Keywords: Education, Networks, Communities of Practice.

INTRODUCTION

This research is focused in the educational activity, in the context of "space-time units" in four Portuguese schools (during a three years period), namely it focuses on the relationships and bonds established in the construction of educational networks, seeking to understand the dynamics of knowledge and knowledge production, constructed and mobilized by the actors.

The school is a privileged place to analyze the relationship between different knowledge(s), emphasizing the need to systematically examine examples of innovative educational networks and how effective it is this process. Today, innovative practices are becoming increasingly important. These different schools have been characterized in the literature by being able to make progress in four key areas: the consideration of student experiences, changes in teaching and learning, redefining the school's organizational structure, and in their ability to establish contacts, networks and partnerships.

The construction of this object of study was done by pooling the idea of school context and the innovations of educational practices, articulating implicit theories that guide people's acts and performances, in order to study the knowledge(s) under consideration.

This research was conducted by means of an interpretative approach based on three movements - phenomenology, ethnography and grounded theory. They are different but can be reconciled in order to allow for a more comprehensive research style. This study was configured as a research proposal with qualitative methods, mostly interviews, logbooks and observations in classrooms and in various locations within the four schools selected for this study.

The schools were intentionally selected because they exhibited characteristics of visible break with the paradigms of traditional use of Pedagogy, with unique educational projects, and with daily practices that perform an innovative contribution in the Portuguese context. Moreover, this success certainly depends on the ability of the actors mingling the pedagogical and organizational dimensions, and it seems to have resulted in a paradigmatic rupture performed at the organizational model for the officially established. From this perspective, schools seem to take autonomous forms of regulation, with changes having consequences at the organizational and management fields. Therefore, we can talk about a new concept of education.

However, the most important determinant of the selection of the schools surveyed attaches to educational success that goes far beyond the achievements in education, creating autonomous citizens (not only educated students for citizenship, but citizenship educators), as noted by Mendes (1999, p.252), "within each group, each child acts as a participant in a project in which one learns to be independent-with-others. Not only educated for autonomy, but through it, on the banks of a free colored by the requirement of responsibility".

We count on the contributions of Charlot (2000, p.78) who says that "the relationship with knowledge is the relationship with the world as a set of meanings, but also as a space for activities, and fits the time", to steer the I look at these schools, while spaces-time units not only the production and mobilization, but also the relationship to knowledge.

Reflecting on knowledge is also reflected to some space and time which falls on ownership and significance of the subject with the world on their identity, establishing relationships with others, which require time and space activities will never be end. As Charlot (2000, p.79) these are the constitutive dimensions of the concept of relationship to knowledge.

> Analyze the relationship with knowledge is to study the subject faced the obligation to learn in a world he shares with others. Analyze the relationship with knowledge is to consider a symbolic relationship, active time. This analysis concerns the relationship with knowledge that an individual subject falls into a social space.

In this sense, what drove me to this research was the fact of wanting to identify, understand, interpret and analyze the mobilization process, production and significance of knowledge and knowledge produced in the innovative practices that occur in schools. I adopted a perspective that was significant to me, and to find one that reflects these experiences and practices in the school context stressing that there was no question of intention of a comparative study involving the four schools surveyed.

What I consider important evidence in this telling of my researcher is that, even with many difficulties in putting together what I proposed, to materialize the principles I believe in and that are dear to me, I can believe that it is possible to build another school, another of an education, that we do, students and teachers, more human subjects. We emphasize that all the experiences, brands and marks of my path, so fundamental now that I find myself, have given a new tone to my walk, both on research in teaching, influencing my eyes and my reflections on the production of knowledge and teaching skills, evaluation of innovative educational practices in the everyday life of the school, revealing thus further questions, concerns, and uncertainties that are beginning to accompany me on this journey as a researcher.

THEORETICAL FRAMEWORK

This research is focused in those moments of reflection that happen in school. Especially it draws attention to the relationship between education and the school to understand that education is a cultural selection among existing knowledge, indulging in a lot of work reorganization, restructuring and didactic transpositions that determine the content and teaching practices.

Furthermore, we discuss the idea of networks, as a not recognized reality, but historical, as well as the innovative practices, articulating implicit theories that guide the way actors perform, since these are the synthesis of experience, and therefore are more that one way to find meaning in the present and the images that represent guidelines for analyzing the set of wisdom and knowledge that I seek to investigate the construction of educational networks, triggered in schools.

To understand the activities of the school context requires being willing to see beyond what others have seen, and much more: being able to fully dive in a certain reality to search for:

> references to sounds, being able to swallow, feeling the variety of tastes, walking and playing things and people, allowing them to be touched, smelling odors that reality faces every day along the way (Alves, 2002, p.7).

Based on the contributions of Certeau (2004), we understand that the school context is filled by multiple and complex negotiations, where you can learn social rules and behaviors, make choices and decisions. In these spaces-time units that occur day-to-day,

> weave / unweave / retec our values, our worldviews, our ways of being in the world, in a continuous and uninterrupted tension and multiple and complex negotiations (Azevedo & Alves, 2004, p.8).

Thus, in the educational institutions governed by this logic, with *a priori* rules being set by superiors who hold the power it is necessary to accept them and follow them. But on the other hand, the subjects also act on them, reverting their logic, shifting borders, creating space for the unexpected, thus enabling the development of the teaching office in accordance with the beliefs and principles that have and can often express values not covered by the official rules.

Certeau (2004) argues that daily life in schools is made up many times in spaces-time units invisible to the eye totalizing and crystallized. However, if we consider the uses and tactics that subjects ranging from developing and creating this same logic crystallized and totalizing, you glimpse other / new horizon that will allow the (re)invention and (re)creation of what is already given, that is laid in the first place.

As definitions of change, narrow concepts of innovation has given more comprehensive forms, and with less clear notions, for example, comparing and defining innovation as an end product of a technology or engineering process. Newer concepts found in various disciplines a proposition of innovation as a learning process involving the distribution and circulation of knowledge among the people (Perillo, 2007).

Seeking paths towards the art of weaving networks in education involves questioning beyond mere appearances. Understand, from whatever point of view and philosophical foundation, involves "re-flex" on the human condition, which are rooted primarily on the issues of knowledge, education, education, and ultimately the school itself.

One of the fundamental functions of the school is to help students organize and reconstruct the knowledge they already possess, to think about what they already know, making sense of experience, using for this, appropriate instruments of various areas or disciplines.

The dialogical relationship allows understanding knowledge as encounter, from the reality of every learner, in a collective construction that prioritizes respect for cultural diversity, religious, ethnic and social. A network of meanings is formed, a process of self-knowledge that allows the establishment of the identity of human beings and their social interaction. Thus, new players emerge in History, active citizens, aware, critical, and committed to the transformation and collective building of a society more humane, just and compassionate.

Today, transdisciplinarity is expressed in the educational proposals of the schools, seeking to understand the complex process of building knowledge, recognizing at the same time, which is between, through and beyond each discipline.

Thus, schools with vision and transdisciplinary networks are connected in space boosters, reaffirming and expanding the identity of each institution to an adequate education to the demands of today. From this reflection, we might ask: What does the metaphor of the network? According to the dictionary, the word comes from the latin network (*rete, is*), and in its original meaning it is a set of twisted, with empty spaces, set by "we" or points, forming a sort of open for tissue fishing and hunting. Over the centuries, the network was renamed concrete or abstract points, interconnected by various types of relationships, and his concept was expanded to several issues, such as neural network, social networking, network of schools, etc.

Thinking about the art of weaving a network, we can see the image of the encounter of different twisted, forming "we" that border the existing spaces and translate their life experiences. Venues representatives of not knowing, the opening for a dynamic movement, making connections and expanding the vision for knowledge that emerges in each step of the weaving. Therefore, the "human man" has knowledge as against weaves networks, builds, unties reconstructs the "we" of the crossing, surprising themselves with their potential and the way forward following the lifelong learner.

We must say that we, humans, to be formed effectively as human beings belonging to this or that group, we need to take part in collective activities and learn to live among other people. That means the world that exists prior to each human being is filled with resources for living, whether material or symbolic resources. It also means that these resources exist in a first time overseas and the people must necessarily be internalized and appropriated by humans. Thus, it means that these resources are external to people and must be adapted, internalized. In short, it can be argued that the multiple dimensions of our social lives were - and remain - formed from the resources available to live and which were created in the midst of social relations. That is, each one of us, in full, is continually "educated".

The process of weaving networks is a work of art based on the values of creativity, innovation, respect for differences, to confront and overcome challenges, and the humility of not knowing and knowledge, built by the joy of "we", the spaces that looks to expand an educational proposal that goes beyond the individual to live and embrace an ethical, social and citizen. The human being is endowed with abilities to learn, develop talents, and education networking happens in a creative process, respecting differences and building knowledge on the relationship of dialogue, during and at the road traveled.

Network implies one another, leading to awareness of being learners on the dynamics of human existence and consolidates dreams in a circular motion. Networks are interwoven threads, woven by the boldness of each point and towards a social interaction. From this perspective, the mission of educational networks are dynamic, forward, enhance skills, build knowledge, bringing together people and institutions, to realize dreams of a comprehensive education that has as a priority to educate for life, from the recognition of purpose and alliances for the joint realization of the objectives.

Thus, the socialization process of human beings and their integral education do not end one day or have predetermined points of arrival. Rather, these processes are confounded by the continued self-production of multiple modes of living human existence. They, therefore, turning to history as a wide beam of possible entanglements of which only a small portion comes to be considered.

The dream of a more humanized world requires hope, boldness, confidence, courage and constant learning. Paulo Freire (1998) has resulted in a happy way the following proposal: "Coming out as a social and historical, as a thinking being, communicating, transformer, creator, and maker of dreams". Therefore, the importance of establishing collaborative networks is anchored in universal values, constituting a proposal of cooperation and solidarity in the development of projects between different organizations and people that integrate them.

The network of relationships in schools, between schools, in the social context in which they are integrated, will expand its field of action along with the different social actors. New answers are being made in order to face the complexity of current demands and, market requirements in a dynamic of openness to the new organizational concepts allowing a participatory management. Schools' mission, vision, values, identity and strategic options in networks enable the continuous flow of communication, integrating theory and practice in quantitative and qualitative responses into a joint intervention in society. The potentiation of human experience is mobilized through interaction and relationships' exchange, allowing the emergence of a new worldview, new paradigms, of a network culture that promotes active citizenship and human life dignity.

One must understand the term education in the broad sense, as the set of practices that the companies are preparing to convey to newcomers the knowledge they think are important to live. In modern societies, and strongly influenced by urban life, the school is, par excellence, the environment that is dedicated to the educational activity. But even in these societies the school is not the only environment where education is an integral part. The knowledge that the school selects are a valued part of the asset that are considered necessary for new members of a society, but does not exhaust the set of socially valued knowledge and should be taught. There are many other kinds of knowledge that are important for reproduction of cultural life and are taught that when you engage in certain social activities throughout life.

The world of work, with its countless differences, is full of knowledge that are taught and learned. The way of weaving a net, writing, speaking, to relate to people is an important knowledge, but is not usually the result of school learning.

Both dimensions of social life strongly marked by the writing on the aspects traditionally transmitted orally, there are elements of cultural heritage which should be appropriate and if they are not, people run the risk of not engaging with fluency and naturalness in the activities in which they are requested.

In short, there are several ways to develop the educational activity on the network and they are all fundamental to the cultural heritage of a group that inherits from his ancestors is passed and serves as a means for new generations to live.

The school, despite having a central role, is not enough to teach everything a person needs to learn. This sentence doesn't intended to be neither a criticism of school, nor a devaluation of what she does. On the contrary through this ideas it's possible to think the school in close relation with the world of culture and society. These are relationships that can determine fruitful dialogues and partnerships that school can establish with other teaching agencies, aiming to global education of the people.

The recognition of lifelong learning for all as an imperative of today's society, where personal growth and development intersect with the development of citizenship, has been to re-education "in the heart of society" (Delors, 1996) as a central requirement for democracy, for which the school can not be responsible alone and closed the reality in a self-reproducing process of a monoculture. Freire (1998) considers that the educational phenomenon is too important to be a monopoly in school. We need, in a human perspective and community, we create a *training system* in the educational context is to extend and interconnect in a complementary dynamic, able to challenge and enrich their practices. In the community network training, you can admire two poles of the educational context:

- The territorial pole, consisting of the family, local authorities, associations, production structures, etc., Which should take responsibility for creating conditions that enable people to achieve a base of rich experience, authentic, differentiated and healthy conflict;
- Polo school, responsible for transforming life's experiences in cultural instruments suitable for modern society, allowing people to reflect on the life experience to turn into a cultural experience and thus able to intervene actively in the preservation and creative transformation.

Thus, the integral education becomes a matter that concerns all citizens who become actors and not mere passive consumers of an education provided by institutions, undermining the various social partners in their capacity as proposed in the 45th session International Conference on Education (1996).

Encouraging the commitment of all partners such as teachers and their organizations, students, upon moral and spiritual, family, business, media and intellectuals, artists and scientists to contribute actively to the creation of a school understood as an active center of learning, intellectual, moral, spiritual, civic and professional adapted to a changing world.

Synergies from the formative interaction between these two types of spaces (pole school and territorial pole) with different educational and social responsibilities, but complementary, forces the thinking of education in full within a territory (in terms of physical and social) articulating policies and lines of action that should be integrated, thus enabling approaches carry out in conjunction.

Moreover, the net of thinking about the school presents itself as a way to solve the so-called "school crisis", about which some Portuguese authors reflect (Canário, 2006; Afonso, 2003; Antunes, 2004; Barroso, 2003; Formosinho, 2005).

What is at issue today is whether the "school crisis" is essentially a crisis of *efficiency* and, therefore, can be resolved in a functionalist manner, or whether it is a crisis of *legitimacy*, which implies that is not likely be resolved only within the school system, not only seen as a problem school. (Canário, 2006, p. 60)

This dimension of the opening of school, in its various aspects, is central in the processes of change and innovation *in* the school *and*, once they are organizations with the capacity to improve, but that hardly could do alone.

The definition of comprehensive education includes various approaches. To develop this argument, it becomes necessary to define education as an integral concept related to the development of substantive capabilities of individuals to promote greater equity and social justice. It is supposed to be a quality education for all and articulation of public policies in health, welfare, culture, sports, and finally, the set of policies needed to educate citizens and encourage effective forms of social cohesion that are the basis of a more cohesive society, pluralistic and democratic.

The school is the starting point for any process of developing comprehensive education, given the high capillarity of the school network, generally distributed throughout the country, in urban and rural areas. The challenge is: to what extent the school is being able to build bridges between formal and comprehensive education? The school is encouraging the construction of bridges, internal and external to it, for the building of networks that allow for comprehensive education?

It is considered that today the formation of networks is a key incentive to the advancement of knowledge and organization of society. The advancement of knowledge depends increasingly on collective work. Unlike the knowledge produced in the past, especially that valued the individual scientist, today the development of science and technology is the fruit of many networks, which are intertwined. The same dynamic increasingly stronger new forms of social organization that differ from classical forms, such as political parties and unions, and go beyond ideological cleavages and / or class, taking a key role in transnational advocacy and suprapartisan, as the environment.

However, the schools often have difficulty leaving their own walls or even build bridges internal to the school to encourage the formation of knowledge networks and media. The school may even want to change and innovate their routines and practices, encouraging interactive networks that strengthen the integration and articulation of public policies. But there are bureaucratic, institutional and organizational issues that tend to hamper the construction of bridges needed to strengthen the networks that sustain a policy of comprehensive education.

Promoting holistic education is not a simple task, but a great challenge. The building is a process that requires much effort and dogged persistence. First, comprehensive education has to do with a set of activities that go beyond the formal curriculum.

It has to do with the fact that the school build bridges and strengthen networks of integrated action. In other words, much depends on management style, leadership of directors, incentives for community participation, the school team. But it also depends on the work done by teachers.

The teachers' work consists of various activities that are made to organize a collective way in which teaching and learning takes place. It is not restricted, therefore, the contact face to face with students, nor is it restricted to individual relationship with each student. The work of teachers is linked to the structure of institutions, with emphasis on the place of power relations. It is also linked to forms of interaction that regulate the action of teachers with other people, be they colleagues, administrators, managers of institutions, students, and family or partner institutions.

CONCLUSION

Given that culture is the knowledge that people use to generate knowledge and interpret their experience, we intended to understand, from within, the behavior and ideas of the members of a group. Instead of searching for a subject to observe, we tried to play the role of an informant from the group culture. Several implications of these ideas in education, when considering the perspective of ethnographic research, occur particularly with regard to differences between the work of anthropologists and researchers in education. Also, it should be noted: first, the need for the use of theories that consider the social and cultural aspects of interpretation and discussion of results; secondly, the need to take into account the different elements that make the lives of students and school teachers, not by isolating the activity of these elements. These ideas are coming from the perspective of Lave (1988) by focusing his research on the nature of daily activities and relationships between the social system and individual experience.

We tried to understand which were / are the knowledge the subjects mobilize and research to produce meaning in order to compose a repertoire of learning that underlies and sometimes rebuilds their actions as professional teachers. It gave the opportunity to understand how we can make another history of education and teaching, which is full of possibilities.

The sense in continually pursuing new opportunities for action and others are necessarily tied to search, incessant, to offer students a quality education even better, a formation that extends the repertoire they carry, allowing them to act independently, creatively and critically face of the reality they experience.

The educational process whether formal or non-formal is always a social action, since it is based on relationships established between individuals (teachers and students) who become apprentices from each other. There's no escape from sociability, and education, by itself, and intensifies already presupposes that action.

Being a social work, education is not neutral, acting directly on the company as it transforms the relations between individuals. It may thus be contributing to a reproductive dominant ideology, critical eye, or can be liberating, when formed by its staff and focused on building awareness of responsible in a humanistic view. Therefore, if education is intended to build citizenship is within its premises a culture of cooperation among individuals. To educate is to raise awareness of the acts committed and take responsibility for them, seeking continuous improvement of people, which results in the formation and transformation of society as a whole.

It happens in the space of social relations. In the case of a cooperative organization, these relations are based on the interests, needs of its members and objectives of the association. This educational process is historical and follows on from generation to generation, always occurring mutation and adaptation necessary for the accumulation of culture and knowledge generation dialogically, in the interaction of individuals, seeking consensus and understanding of all with regard to social relations, to life goals, work, or in relationships that are woven in the act of living.

The relationship between cooperation and education takes place in social practice, human relations throughout the experience and exchange of experiences. All people should relate to unify the act of educating the relations between individuals within a society. The co-participation in education is the responsibility of all members of society, since we are grassroots and co-receptors at all times of social transformation and universal consciousness.

At home, in the street, at church or school, in one way or many, we involve all parts of life to education: to learn, to teach, to learn-and-teach, to learn to do, to be or interact. Everyday life mixed with education.

The human being educates and is educated in the way he lives in society. And it is through education the he gets a sense to his life, through manifold influences, to the extent that you live and learn in society. Even indirectly, in an informal way, each person helps the formation of consciousness of others. Therefore it is a practice that affects each other.

Pierre Lévy (1999) states that,

> Education as social action or social practice appears as an action between individuals or as a practice on others, seeking to influence them in their ideas and their values, their ways of thinking, to interpret social life, especially the reality of cooperative suggesting or leading them to conduct and worldview in favor of the cooperative nature of the practice. (...) In addition to the different roles that education practices can play in the organization and operation of a cooperative school, it poses the challenge of this production of knowledge, or the collective intelligence (p. 29).

Thus knowledge is a collective construction, relying on the school as a place for this process. Today the school has a far more evolved as the enhancement of human being; it considers the student's participation in the construction of their knowledge along to others, but, in practice, this is extremely difficult of being made.

The school practices are isolated from theory, and that is where change is needed, urgently. An emerging alternative is to link education to practices of cooperation. Thus, qualitative changes in the educational proposals will not be effective if it does not include the know-how that was collectively, and long-accumulated by the teachers. These changes will not be effective if they don't go deep in the structures that organize the work of teachers, including those related to power relations and economic constraints. Without it, attempts to change are at risk, namely not consolidating new possibilities, or being swallowed up by practices or simply by promoting superficial changes.

Teachers are subjected to a series of prescriptions for various orders that tell them what they should and should not do. In short, what a teacher does and can not in any way, exclusively the result of his individual will. If there is a field of possibilities within the reach of the actions of teachers and whether it is necessary to focus on ways that this field can take, it is also prudent to consider that these actions will actually be creative if they are supported by structural transformations that generalize and institutionalize the innovations.

Thus, taking into account what the partners already know and what they do only because they collaborate, the fabric of the comprehensive education networks leads us to consider the integral education in a positive manner and not as yet a strong requirement that falls on the shoulders of already overburdened school.

The value of this network of instances in which we teach and learn can lead us to conceive education as a whole broader process that has different actors and in which the school occupies a central but not exclusive. Schools and educators have the responsibility to train people for social life, but will never be enough. This is exactly why they can open up to other bodies and actors, adding to the generalization of training processes they perform.

The school as a learning organization, as a learning community, including not only students, but all its members, is today a central idea for change in a society that requires attitudes and dispositions of lifelong learning, where learning is individual be framed and promoted in the context of organizational learning. Here that cross different perspectives that have contributed to innovation in educational practices, *curriculum development, school-based training focusing on school and review school-based or institutional self-evaluation*, pointing out that this centrality of the school does not mean isolation, by otherwise requires and needs of external openness in seeking the establishment of support, partnerships, training networks that allow you to increase your learning potential, learning from other legal institutions, cultural associations, social and economic.

The new organizational paradigms suggest a reform in thinking and propose a challenge to school: tackling and take the complexity. Unlike adapt to the changing context, the idea is to create a flexible environment in school, aware of the complexity of education, open to change the endless search for better answers to the problems of students, parents and teachers. The school as a place of living and working in a school is moving as well as the context is in motion.

Therein lies the importance of bringing networks into the school because it innovates, enhances a new view and perspective of the world. Networking allows us to leave our place and get to know the other's place. It also allows to learn how to build a common place centered in what unites us, and not to fight for what divides us.

An innovative actual reflexive, creative and open practice aims to implement concrete actions that promote interdependence, reciprocity, cooperation, participation, exchange of experiences, collective and shared efforts exchange between different education systems and other organizations to promote events for study; and reflection on educational issues, which are part of knowledge construction. This is a challenge to be embraced in community, through a historical and social perspective, to weave networks in education.

Abstract: The Portuguese system of music education has long been characterized by the existence of educational subsystems (generic, specialized and professional) that stem from different philosophical foundations, develop different pedagogical strategies and aim at different artistic goals. The fact is that students in the generic subsystem seldom learn how to play an instrument or read notation, rarely have their musical aptitudes tested and almost never receive appropriate training and music vocational counseling. This article focuses on theoretical and research foundations for the proposal of instrumental group teaching as an agenda for democracy in Portuguese music education. The concept of music as a sort of "external body of knowledge" than can be understood and appreciated by everyone without actually learning how to play, sing, read or compose music is rejected on the premises of philosophical incongruence. Promoting aesthetic appreciation of music without its practice perpetuates the failure of generic music education.

Keywords: Music Education; Democracy; Musical Instruments; Group Teaching

INTRODUCTION

The existence of three subsystems of music education in Portugal (generic, specialized and professional) represents a particular educational case within the national curriculum. No other subject or area of knowledge exhibits such curricular complexity in the Portuguese educational system. For that reason, no other subject presents itself to citizens in such a variety of possible paths: students can study music in the general school, in a conservatory or academy or also in a professional school. However, these multiple options are offered at different age levels, and do not result from an integrated or intentional perspective of music education policy, but rather from a quite casual collection of historical decisions concerning different educational institutions that coexist today (Vieira, 2006). The desired articulation between the subsystems (which is actually announced in several legislative documents that regulate them) is not efficient, thus frustrating any reasonable expectation for good musical aptitude detection and vocational counseling (Vieira, 2009).

MUSIC EDUCATION FOR ALL: BRIEF HISTORICAL OVERVIEW

The generic branch of music education, as we understand it today, is rooted in the establishment of the public system of education itself. After the introduction of music in the curriculum of the University of Coimbra in the 13th century, the opening of Jesuit schools in the 16th century was another important moment for the democratization of schooling in general, and of arts in particular. During the 18th century, and under the influence of French Illuminists, the Marquis of Pombal (1699-1782) expelled the religious orders from Portugal. New schools emerged, in which women could also study. Luís António Verney, a "*estrangeirado*" (literally a "*foreigned*") who studied in France contributed to the opening of "low schools", which were open to everyone. The curriculum in these schools included music (Verney, n/d, 123-149). During the 19th century, which was an era of political instability and confrontation with the new liberal ideas, several attempts of school reform were made, but only a few had music teaching in consideration. On the other hand, the 19th century saw the creation of the first music conservatory in Portugal (the Lisbon conservatory in 1835, which was followed by the creation of Porto conservatory in 1917 and other conservatories in the 1960's). These schools became the only schools that provided a consistent music education curriculum, a situation that is still valid today.

The change from the 19th to the 20th century was a period of strong nationalistic movements all over Europe. The majority of national anthems was composed during the 19th century and 20th centuries and Choral Singing emerged as an important means to stimulate national feelings and cohesion. In 1906, music (which

was presented in schools as "*Choral Singing*") was introduced in the curriculum of the recently created *Liceu Feminino Maria Pia* – the first high school for women in Lisbon. This subject was seen as a "feminine subject" that, unlike other subjects, had only qualitative grades and evaluation (and not quantitative), such as "bad, mediocre, sufficient, good and very good" (Artiaga, 1999, 58). Choral Singing was introduced in all the other high schools in the country in 1918 and the school programs produced by the government underlined its importance for aspects such as "voice education", "aesthetic education", "development of nationalistic feelings", "contribution for moral and civic education" and "for the development of solidarity" (p. 58). The "coup d'etat" of 1926 inaugurated a period of dictatorship that lasted for more than forty years. During this period, the abovementioned goals for the Choral Singing subject were reinforced. Although some aspects showed improvement (evaluation, for instance, started to be qualitative) the contents of Choral Singing remained highly "non-musical". On the contrary, the main goals were more related to social and political messages that the Government wished to pass through the texts, than to music itself. Choral Singing was, therefore, used a means of governmental propaganda – a way to glorify Portugal and foster patriotic feelings. At this point, in terms of music education, the country was, therefore, divided into schools that taught music, and schools that taught music as a means to learn something else.

Although the generic branch of music education has deep historical roots, the idea of music as an autonomous subject, with its own intrinsic value, and accessible to all students in public school is very recent. Palheiros (1993) dates it to the introduction of the "*Educação Musical*" course in the curriculum of 6th and 7th graders in 1968. For this course the government created the first official programs with specific music goals, instead of placing it at the service of politics or ideology. The 1960's and the 1970's were also very important for the development of music education, due to the visit of several foreign music pedagogues and composers who were invited by the Portuguese Association of Music Education (APEM). Methodologies such as the ones proposed by Orff, Willems and Dalcroze were presented in numerous workshops and started to have a strong impact in Portuguese music classrooms. Notable composers such as Murray Schafer and Egon Krauss were also invited with the specific purpose of fostering a "more musical pedagogy" in portuguese music classrooms. The workshops were attended by many teachers, as Macedo (1978, p.20) testifies, for example, in her report about the workshop "Sound environment and music creativity" led by Murray Schafer. This workshop was attended by 80 teachers and students, from Porto, Matosinhos, Vila Real, Chaves, Amarante, Lisboa and Braga, among other regions.

The 1970's were, indeed, a period when Music Education as a school discipline started to focus on specific aspects of the musical language and on the development of creativity and aural discrimination, and no longer functioned as a mere vehicle for the transmission of other ideas, concepts or propaganda. This was, undeniably, a great step towards the democratization of music knowledge and of the musical education of the common citizen who did not attend a conservatory.

However, the lack of preparation of the conservatory-trained music teachers to teach big classes in the generic schools was a sign of the big difference between the music education offered in the specialized and generic systems of music education. In fact, the music curriculum in the conservatory was and is mostly focused on individual (musical instrument) instruction, whereas the generic school was and is trying to "educate the masses". On the other hand, the new music education pedagogies made known to Portuguese teachers in the 1970's were directed to group teaching and served as pedagogical training for specialized musicians who started to teach in general schools. The impact of those pedagogies (such as Orff, Kodaly and Willems) was, therefore, clearly greater in general schools than in the conservatories, where they were restricted to the "*Music Education*" or "*Music Initiation*" class subjects. "*Instrument*" individual classes, "*Music History*" classes or "*Composition*" classes in the conservatory remained obviously untouched by this "group pedagogy revolution".

While the public school was gaining access to music education, the contrast between the pedagogical practices being adopted there and the conservatory pedagogical models became more and more evident. However, no psychological, pedagogical or social reasons could be given for such pedagogical differences (Vieira, 2006). Egon Krauss alerted for this fact in a 1974 conference in Portugal, entitled "*The teaching of music as a compulsory subject in primary schools*" (*Author's transl*.). His observation was so clairvoyant that it can still be seen as meaningful today:

> *The dangerous process that converts the subject of "music" from a compulsory subject in all schools into a subject that is only available to a few more musically apt students becomes a serious basic educational problem. In general, the so-called "talented students" are students that were musically advised at the appropriate time, but not by the general school system of music education. For these so-called talented some countries created special institutions: schools or educational branches of*

music education, secondary music schools, specialized higher music education schools, special music schools for young people, a.s.o. All these institutions aim at compensating the lack of music education in general primary schools, in order to ensure a new generation of music teachers for the next generation. Music Education for all and professional music education are, however, two completely different problems. The efforts made by some countries to ensure specialized music teaching for children with a music vocation or talent were already a consequence of the abandonment of music teaching in the primary schools and its transference for specialized schools. A music pedagogy concept of unilateral promotion of talent and capacity accelerates the fall of general education and promotes musical analphabetism (pp.1-2), (Author's Transl.).

It is important to underline that Krauss was not opposed to the existence of specialized schools and conservatoires that could "go beyond the music education administered in primary schools" for "students with a special inclination for music" (p.2). What the composer and pedagogue defended was that "more important than the promotion of talents was each child's right to music education" (p.3). In fact, the author defended that "human beings who have had access to systematic music learning experiences at a young age are almost always '*talented*'" (p.2). The curricular irony pointed out by Krauss, and that should also be questioned today in Portugal, is that conservatories and academies, as vocational music schools for the talented, may actually not be attended by the most talented students. Therefore, the promotion of talents should start with the principle of equal opportunities.

Two strategies were developed in Portugal since the 1980's in order to make the access to formal music education more democratic: the "articulated system of education" (Portuguese: "*Regime Articulado*") and the "cultural enrichment activities program" (Portuguese: *Actividades de Enriquecimento Curricular*). The "articulated system of education" was first promoted in 1983 (Law-Decree 310/83, Art. 6, nr.1) in order to reinforce the connections between the general and the specialized schools, particularly in what the students attendance was concerned. The "articulated system" allows the student to study in both schools (regular subjects in the general school and music subjects in the conservatory or academy), and it represented a great increase in the number of students in conservatories and academies up to today. It also represented a clear improvement in terms of expansion of specialized music teaching towards the sphere of the general schools. This desirable approximation between the generic and the specialized branches of music education (pointed out as a research result by Vieira, 2006) has been thoroughly studied by Pacheco (2008) in the case study Masters' research project "Music Education in Articulated Attendance at the Vale do Sousa Conservatory: Vocational or Generic Function?" (*Author's transl.*). *Articulated attendance* of both the general and the specialized schools is seen in this case study as an optimal way to foster democratization of music education under the present circumstances in the country. The "cultural enrichment activities program", as a music education democratization strategy, emerged tentatively in the Basic Law of the Educational System (Law-Decree 46/86), (Portuguese: *Lei de Bases do Sistema Educativo*"), and evolved through the years, under different legislative improvements, up to its effective creation with *Despacho 12591/2006* (Ferreira, 2009). The concept underlying these "cultural enrichment activities" was the offer of extra artistic education, sports or foreign languages to the students in the general schools. The legislation instructed, for instance, that the students must continue to attend music in their regular generalist classes with the general and/or the specialized teacher, but also have access to optional music classes in the context of the "cultural enrichment activities", usually after school hours. Ferreira (2009) has concluded that the optional and leisure nature of these activities, alongside the fact that they tended to replace the regular compulsory music instruction in the general schools has actually led to a decrease in the presence of music activities and music education in the schools, thus constituting a step back in the democratization process. In a word, the 1980's and the 1990's have witnessed both improvements and failures in the process of democratizing music education, of making a consistent and systematic music education curriculum more open to all students in the country.

INSTRUMENTAL GROUP TEACHING: A STEP FURTHER IN THE DEMOCRATIZATION OF MUSIC EDUCATION

Despite the ever-increasing number of students enrolling in conservatories and academies under the "articulated system", particularly after *Despacho 12591/2006*, the fact is that the vast majority of students only has access to the music education offered in the general schools. Despite the dilution of differences between music education in the general schools and specialized schools due to the increasing similarities in teacher training degrees for the different branches of music education, the fact is that teachers still tend to conform to the generic or the specialized branches and adjust their teaching strategies and pedagogical goals according to different ideals of education and different social purposes (Vieira, 2006). Despite the issuing of

laws that encompass all branches of artistic education and try to promote the aesthetic education of all citizens, aptitude detection, and the democratization of artistic performance practices (such as Law-Decree 310/83, Law-Decree 344/90 and Law-Decree 6/2001), the fact is that the pedagogical practices in music education classes in the general schools remain quite different from the pedagogical practices in music classes in conservatories and academies. This is awkwardly so also at the elementary school level: general schools provide "general music education" and specialized schools provide "specialized music education", even at an early age. This fact contradicts the traditional concept of "specialization" itself: in other school subjects specialization is the natural consequence of a few years of study and vocational pondering and counseling (Vieira, 2008). In music, children can officially choose specialization (or have someone choose for them) as early as 6 years old, when they can enroll in a conservatory or official academy. This, of course, bears no relation with children's music aptitudes and their detection. However, it shows that the specialized system of music education is built upon an innate perspective of talent, a perspective that justifies the attempt to minister a specialized training as soon as possible to the supposedly talented children.

The major difference between music education in general schools and in specialized schools can be found in instrumental learning. General schools rely on the paradigm of aesthetic education (Reimer, 1989); specialized schools are focused on performance (Elliott, 1995). General schools promote aesthetic contemplation of the work of art, aesthetic understanding of an outside object; specialized schools promote the production of the work of art itself, aesthetic creativity and embodiment of the art piece. The concept of music as a sort of "external body of knowledge" than can be understood and appreciated by everyone without actually learning how to play, sing, read or compose music should be rejected on the premises of philosophical incongruence. In fact, music education in the general schools might be centuries behind compared to foreign language learning. Separating an education system that promotes aesthetic contemplation (and the consequent ambiguity of an integrated perspective of arts learning at an early age) from an education system that fosters music literacy might be as social unjust as training a group to play for the other group to listen. Babel *versus* understanding; chaos *versus* cosmos. History shows that this sort of curriculum structure dates back to the early pre-Christian Jewish communities, and could be found in ancient Greece (when the slaves were the ones who knew how to play music for the masters - who couldn't play a note, but were very happy to listen and appreciate.).

Small (1996, 184) underlines that this notion of schooling as transmission of an abstract body of knowledge pervades the entire system of education, in many school subjects (from science to visual arts, from geography to music). The author points out that in music education, as in general education, "the concept of the product is dominant" (p.193). However, general music education looks at music as the product to be known, as the work of art to be appreciated; specialized music education, on the other hand, looks at music as the product to be made, to be produced, to be interpreted or composed.

Instrumental performance and instrumental learning, however, pose a number of difficulties for the public school system. They suppose the existence of musical instruments for all students and the support of specialized instrumental teachers whose training is long and strenuous. The general schools have relied mostly on the Orff *instrumentarium* (with the support of the corresponding teaching methodologies) and more recently on the guitar; instruments such as the piano, violin, cello, double-bass, trumpet, clarinet and many other orchestral instruments, being much more expensive, have remained a study privilege of the conservatory and music academy students.

Instrumental group learning, therefore, emerges as the next step further in the process of democratization of music education in Portugal, especially in the early stages of development and schooling. Financial reasons may support the promotion of music instrument learning in a group context; in fact, the possibility of hiring one single teacher to teach a musical instrument to many students at the same time makes it highly predictable that group methodologies of instrumental teaching will increasingly be adopted for not-so-scientific reasons. Luckily, however, a few studies are emerging, particularly in the United States and Brasil, that show that instrumental group learning can be highly effective, if not more effective, for particular ages and under special circumstances (Fisher, 2010, Coats, 2006, Cruvinel, 2005, among others).

Portaria 691/2009 was the first Portuguese government decision in that direction. This legislative document introduced the obligation of instrumental group teaching in the specialized schools, suggesting that the instrumental group teacher should now replace one of the two weekly individual lessons by a group lesson for at least two students. Despite the professionals first alarm response, the specialized schools have been implementing the new directions systematically and under the supervision of some universities pedagogical practice directors.

A few academic studies are now emerging in the country trying to investigate and describe the individual, pedagogical, artistic, social and political potentialities and disadvantages of instrumental group teaching and

collective learning in different pedagogical contexts and age level groups. A research team of the Institute of Education of the University of Minho, in Braga, is developing a research project that intends to question the political and curricular branching of music education in Portugal at the elementary school level, and foresees instrumental group teaching as a possible solution for the improvement of music education and the citizens music literacy and musical aptitude detection. The musical instrument is seen as a possible means, and not an end of music education itself. Considering that there are no such things as "generic music" or "specialized music", and that it is not possible to divide students into "generic" and "vocational", at least at an early age (Vieira, 2009), the research project aims at the construction of a strong theoretical frame (in the areas of pedagogy, specific didactics and curricular policies) that might sustain instrumental group music practices in the generic and specialized public schools. Different case studies and action-research projects are being developed in specialized and generic schools, at the 1st Cycle (6-9 year olds) and 2nd Cycle (10-11 year olds), involving group teaching of guitar, piano, flute, strings, orchestral groups and voice. Although these projects are not yet finished, it is already possible to affirm that instrumental group teaching will be an important part of the future of music education and music literacy in Portugal.

CONCLUSION

The real power of music lies, not in contemplation, but in its practice; not in listening only, but in playing, singing and composing. Music is a language that needs to be spoken and not only heard. One hears better when one can play, just as one understands better when one can speak. The Portuguese system of music education has perpetuated an artificial division between branched subsystems that overemphasize listening on the one hand, and performing on the other hand. Instrumental group teaching and learning as a pedagogical practice might foster a performance approach in generic schools and promote collaborative strategies and aesthetic contemplation in specialized schools, thus bringing them closer together in nature than any "articulated" system might have done before. It might also contribute to a more realistic process of music aptitude detection and vocational counseling, by allowing students to experiment more closely an effective musical practice for a few years, before deciding whether or not to enroll in a specialized school. From the individual standpoint, instrumental group teaching and learning might provide a special music environment where multiple feed-back can be offered, and where peer-learning can stimulate decision-making and increase motivation.

THEME 4
Teaching in a Digital Culture

7 - Synote: A Free Collaborative Multimedia Web Technology Helping Teachers and Students Transform Teaching and Learning in Schools, Colleges and Universities

Mike Wald

University of Southampton, UK
m.wald@soton.ac.uk

Abstract: While users can easily bookmark, search, link to, or tag the WHOLE of an educational recording they cannot easily find, or associate their notes or resources with, PART of that recording. Synote is a free web-based application that enhances student-centred learning allowing synchronisation of transcripts and slides and student or teacher created notes with educational recordings. Notes/'tweets' taken live on mobile devices using Twitter can be synchronised with the recordings of the class. Teachers and peers can give feedback linked to appropriate moments for recorded tasks. Synote's synchronised transcripts enable the recordings to be searched while also helping support non-native speakers and deaf and hearing impaired students as well dyslexic students while the use of text descriptions of video or images helps blind or visually impaired students. Synote has been used successfully in schools, colleges and universities worldwide with students with a wide range of languages, abilities and disabilities.

Keywords: Multimedia, synchronized, annotation, recording

INTRODUCTION

Synote has been developed to overcome the problem that while users can easily bookmark, search, link to, or tag the WHOLE of a podcast or video recording available on the web they cannot easily find, or associate their notes or resources with, PART of that recording (Whittaker et al 1994). As an analogy, users would clearly find a text book difficult to use if it had no contents page, index or page numbers. Synote (Wald et al 2009) is freely available and uniquely can use speech recognition to synchronise audio or video recordings of lectures or pre-recorded teaching material with a transcript, slides and images and student or teacher created notes. In 2009 Synote won the EUNIS International E-learning Award and was described by the awards panel as the most exciting educational innovation they had seen for many years. The system is unique as it is free to use, automatically or manually creates and synchronises speech transcriptions, allows teachers and students to create real time synchronised notes or tags and facilitates the capture and replay of recordings in any media format and browser and stored anywhere on the web. Synote has been developed and evaluated with the involvement of users. Figures. 1 & 2 schematically show the Synote system while figures. 3 and 4 show screen displays of its interface. Figure. 5 shows the manual transcript editing interface with clock icons indicating synchronization points in the text. Figure. 6 shows an example of a print preview that enables students to make a paper copy of the transcript, slides and notes with the synchronization timings. Synote can also automatically create synchronized and searchable audio, transcripts and slides (including titles, text and notes) from Narrated PowerPoint Slides. The synchronised bookmarks, containing notes tags and links are called Synmarks. When the recording is replayed the currently spoken words are shown highlighted in the transcript. Selecting a Synmark, transcript word or Slide/Image moves the recording to the corresponding time. The provision of text captions and images synchronized with audio and video enables all their communication qualities and strengths to be available as appropriate for different contexts, content, tasks, learning styles, learning preferences and learning differences. Text can reduce the memory demands of spoken language; speech can better express subtle emotions; while images can communicate moods, relationships and complex information holistically. Synote's synchronised transcripts enable the recordings to be searched while also helping support non native speakers (e.g. overseas students) and deaf and hearing impaired students understand the spoken text. The use of text descriptions and annotations of video or images help blind or visually impaired students understand the images.

Assessment

It is very common for university students to be assessed on their presentation skills. Typically they will make a short live presentation using slides for which they may be given a mark and some oral and/or written feedback. Presenting live in class is however very time consuming. For example, it could take 10 hours if each student in a class of 60 students presented for 5 minutes, allowing for questions and change over time. It could take 15 hours if teachers and other students provided oral feed back immediately after the presentations. Also while feedback can be given for the WHOLE of the presentation it is not easy to associate feedback with a specific PART of that presentation such as a critical moment(s). If however

807

students record presentations Synote allows teachers and peers to provide feedback linked to the appropriate and critical moment(s) (for example '*you were reading from notes rather than making eye contact with the audience*'). The written feedback can be created live or after the event and the student can read it afterwards synchronised to the recording. It is possible also to provide the feedback in audio or video format (e.g. sign language).

It is difficult to assess students undertaking practical tasks (e.g. student nurses in real or simulated wards or student teachers giving real or simulated lessons). Again, while feedback can be given for the WHOLE of the task it is not easy to associate feedback with a specific PART of that task such as a critical moment. If performance on tasks is recorded then Synote allows teachers and peers to give feedback linked to the appropriate and critical moment(s). Written feedback can be created live or after the event and the student can read it afterwards synchronised to the recording. It is possible also to provide the feedback in audio or video format (e.g. sign language).

It is very common for university students to be assessed on their work in a group. Typically they will be asked for evidence for their contribution to a group. It is however difficult for students to provide evidence for their contributions at face to face meetings as typically minutes only record agreed actions. If meetings are recorded students can annotate the recordings at appropriate and critical moment(s). The synchronised annotations can be made live or after the event and the assessor/evaluator can read them afterwards synchronised to the recording and also provide feedback linked to the appropriate and critical moment(s). It is possible also to provide the feedback in audio or video format (e.g. sign language).

It is difficult for students to really interact in large lectures as only a few students will be able to ask or answer questions. 'clickers'/'electronic voting systems' (MacGeorge et al., 2008) are sometimes used to give feedback or answer in-class tests but this requires students to buy these at the beginning of their studies and carry them with them at all times or they can be given out at the start of the class and collected in at the end of the class, which can be very time consuming for the teacher/lecturer. If lectures are recorded, using Synote teachers can pose questions at points in a recording and provide feedback to students' answers. Students can answer after class or use twitter to answer live in class, with these answers automatically synchronised with the recording. Future developments could include the use of synchronised multiple choice questions.

Speech Recognition Transcription

Synote builds on 10 years of Dr Wald's work on the use of speech recognition for learning in collaboration with IBM, MIT and other organisations in the international Liberated Learning Consortium of which he was a founder member. Google announced in November 2009 that they plan to use speech recognition to caption YouTube videos, a feature available for nearly two years for students using Synote. The availability of 'continuous' speech recognition dictation systems that didn't require the speaker to pause between words led to the Liberated Learning Consortium being formed in 1999 to trial real-time transcription for deaf students in classrooms (Leitch and MacMillan 2003). All students liked using the corrected transcripts after the class but the accuracy from spontaneous speech was lower than from dictated speech and the text was difficult to read without the dictation of punctuation. A few speakers achieved 90% accuracy speaking clearly at an even pace. Readability was improved by developing software to automatically break up the text using new lines or punctuation triggered by pauses in the speech. Further developments in collaboration with IBM included automatically synchronising audio, text and PowerPoint slides (which enabled recordings to be searched) and training the system using spontaneous speech rather than scripts. IBM's ViaScribe (Wald and Bain 2007) also provided a programming interface for the speech recognition output to be enhanced through interoperability with systems that; displayed the recognised text on personalized displays on networked laptops in ways users preferred (e.g. colour, font, size etc.); allowed the recognition errors to be correct in real time by one or more people; and merged the text output from any number of speakers each using ViaScribe. IBM more recently developed the speaker independent 'Attila' system that can be hosted on the web, interfaced with other applications and used to transcribe, edit and display recordings created in a wide range of multimedia file formats. Synote can add user created notes and tags synchronised to the recordings, transcripts and slides provided by ViaScribe and Attila. Integration of the IBM Hosted Transcription System with Synote has simplified the process of transcription.

Classroom Use and Evaluation of Synote

Synote is currently being used by teachers in universities in the UK, Italy, Germany, Pakistan, Australia, US and Canada. Since 2007 Dr Wald has used Synote with over 40 recordings of his lectures with synchronised transcripts and slides for his teaching of approximately 200 students on 5 undergraduate and postgraduate modules in The University of Southampton's School of Electronics and Computer Science (ECS). At the

time of writing there are over 420 recordings publically available on Synote (most with synchronised transcripts) for students to use for their learning. These include lectures of colleagues and guest lectures presented by leaders in their field. The provision of a verbatim synchronised transcript enables students to concentrate on learning and take only brief synchronised notes in Synote (e.g. 'revise this section for exam', 'I don't understand this fully' etc.). This feature is greatly valued by all students, not only by deaf students who need to lipread or watch a sign language interpreter and so can't take notes or dyslexic students or non-native speakers who find it difficult to take notes. The fact that Synote is used and valued by all students means that non native speakers and disabled students feel more included and do not have to use special technology. They have said that they do not like standing out from the crowd by having to walk to the front of the class to ask the teacher if they can record the lecture on their personal digital recorder. Also the quality of recording from a teacher's wireless headworn microphone is significantly better than from small personal digital recorders placed at the front of the class. Students did not like retyping handwritten notes they had taken in class into Synote after the recording had been uploaded and so Synote has recently been enhanced so that synchronised notes taken live in class on mobiles or laptops using Twitter can be automatically uploaded into Synote. This process is shown in Figures 8, 9 and 10.

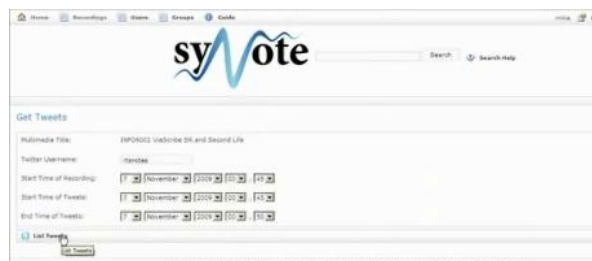
Figure 8: Twitter live notes


Figure 9: Synote's Twitter interface

Figure 10: Twitter notes displayed in Synote

5 university classes (two 1st year classes, one 3rd year class and two Masters classes) with approximately 200 students were surveyed, with 101 students filling in questionnaires about their experience with Synote. The questionnaire results showed that Synote's design to support a wide range of browsers was justified and appreciated with 54% using Internet Explorer, 31% using FireFox, 12% using Google Chrome and 3% using Safari. The results also confirmed that Synote was easy to use as over 80% of the respondents didn't need to read the Synote guide and rated Synote as 4 or 5 on a 5 point scale of ease of use with the remaining percentage rating it as 3. The design of Synote to provide synchronised slides, video, audio and transcripts was also appreciated with over 80% respondents rating Synote as 4 or 5 for being useful overall as well as its slides, video and audio and transcript also each being useful with averages ratings of between 4.1 and 4.5. A slightly smaller percentage rated the Synmark option and the print out option as being useful with an average

of 3.7 and 3.3 respectively on the 5 point scale used. One student commented that if Synote was used regularly then it would become second nature to use all these facilities. 97% of the students wanted all their lectures to be presented on Synote. 44 students in two of these 5 classes identified in more detail how using Synote affected their learning by indicating whether Synote improved or reduced or provided no change in the aspects of their learning as shown in Table 1.

Table 1

	improve	no change	reduce
learning	95%	5%	0%
attention	61%	34%	5%
motivation	50%	50%	0%
efficiency	77%	23%	0%
enjoyment	66%	32%	3%
results	69%	31%	0%
notetaking	53%	30%	18%
attendance	13%	45%	42%

A few students commented that some students' notetaking skills might not develop if all classes were recorded and presented on Synote. Some students commented that if they were ill or had serious problems they would normally still try and come in to classes because they were worried they would get behind in their work and would be unable to catch up, whereas with Synote they would be able to stay at home and get well secure in the knowledge that they would not miss anything as they could learn using the Synote recording. Students stated that it was important that that ALL lectures were recorded so they didn't find that the one lecture they missed hadn't been recorded. Of these 44 students 37% identified themselves as native speakers, 26% as fluent, 28% as having good language knowledge and 9% as having little language knowledge Non native speakers in particularly commented how valuable Synote was for them as it was sometimes difficult to understand lecturers' speech and note-taking in a foreign language was very difficult for them. One commented that they could get words not understood in the transcript translated by Google. Of these 44 students 7% identified themselves as having hearing disabilities, 2% visual disabilities, 11% learning disabilities and 7% other disabilities. Two overseas students wrote:

> *"Synote gives a very clear understanding of module ...It was very useful for me especially as I am a non English native speaker"*

> *"I think Synote is a very good way to listen to lectures. If for example we miss the lecture we can actually listen to it in our own time or if we didn't really understand the lecture we can go back to it and listen to it carefully. I also like the highlighted part whenever the lecturer speaks on the text so we can't actually get lost within long texts."*

Other students wrote

> *"Synote is very useful for students in general, I think at present all they need is to get used to something like Synote. It will then become second nature"*

> *"Synote is the best system I have ever seen for assistive technology it is very useful for me to understand what the lecturer taught after class I hope all school majors could integrate this system thanks"*

Error Correction
Commercial rates for manually transcribing and synchronising a lecture recording are typically around £2/minute [i] (rates vary dependent on quality and quantity) and so it would cost about £90 for transcribing and synchronising a 45 minute class. For Speech recognition to be used it must therefore cost less than this. The cost of the speech recognition will involve licensing costs as well as server and maintenance costs. Manual correction of errors will also be required if 100% accuracy is to be achieved. The Attila IBM speech recognition system used with Synote had available a US and not a UK English voice and language model (a UK model is currently being developed) and had no facility for adding vocabulary or training to individual users' voices and so typically gave word error rates between 15% - 30% for UK speakers using headset

microphones. This compares well with the National Institutes of Standards (NIST) Speech Group reported WER of 28% for individual head mounted microphones in lectures (Fiscus et al 2005). It is important to note that no student themselves ever correctly recognises 100% of a spoken lecture and that many speech recognition 'errors' don't seriously affect readability (e.g. 'a' instead of 'the') or search results. However if improved accuracy is desired then manual editing is required. Analysis of the data shows that typical lecturer speaking rates varied from 120 – 160 wpm with an average around 140 words per minute. With 30% error rates, editing at an average of 14 corrections/minute takes approximately 3 times as long as the lecture itself whereas editing lectures that have a 15% error rate takes twice as long as the lecture. Synote allows transcripts to be created and synchronised manually as well as through speech recognition and this approach could be quicker that correcting speech recognition errors if these are greater than 30%. In the UK, disabled students (e.g. Deaf students) requiring transcription of recordings can pay for this from their Disabled Student Allowance. Universities do not however routinely transcribe or caption all recordings as they claim it is too costly for them to do so. One possible sustainable approach to obtaining accurate transcriptions could be to devise a system where students in the classes themselves corrected errors they find in the transcript, either voluntarily or through being paid or through being given academic credit. For speech recognition systems to be able to transcribe lectures more accurately in addition to having 'local' (e.g. UK) language and voice models they need to be designed for education rather than for dictation. For example they need to:

- Be speaker independent with a speaker dependent training facility
- Be customisable for different subject domains
- Cope with low quality speech signals and background noise
- Recognise or ignore partial words (e.g. hesitations) or 'fillers' (e.g. 'um', 'er')

If two users simultaneously correct errors in a transcript using Synote, whoever last saves their whole corrected transcript will overwrite all of the other's corrections. Therefore a system has been built to split the transcript into separate short utterances which can be edited as Synmarks and saved independently. These separate utterances can then be recombined as a complete transcript. Research is currently being conducted as to the best method of splitting the utterances comparing using the time/silence between words (e.g. 300 ms), the number of words (e.g. 10) or the total time of utterance (e.g. 5 seconds). We are also investigating whether editors prefer utterances to start with a capital letter and end with a full stop. As correctors of errors may themselves make or miss errors a 'triangulation' method has also been developed to compare the edits of different editors to verify their correctness. For example if two or more correctors make the same corrections then this provides good evidence of accurate corrections. This requires storing all the corrections of different editors rather than just the latest edit. Since paying editors is expensive, methods of motivating users to also correct errors as they read the transcript as part of their studies are also being investigated such as awarding points for correctly amending utterances and subtracting points for incorrectly amending utterances. The system developed takes into account that there are different ways to transcribe the spoken word (e.g. I'm or I am).

CONCLUSION AND FUTURE WORK

Synote has been shown to provide accessible and very well received enhancements to web based teaching and learning for all students and to integrate well with other applications including PowerPoint, Twitter and Speech Recognition Software. While Synote has much to offer even without synchronised transcripts, there could be a huge educational demand for speech recognition transcription if it can be made sufficiently accurate and affordable. Further developments of Synote currently being investigated include methods to enable multiple users to simultaneously edit the transcript.

18 - Between Cutting Edge and Bidonville: A Reflection about Elearning

Lia Raquel Oliveira

Department of Curriculum Studies and Educational Technology, Institute of Education, University of Minho, Portugal
lia@ie.uminho.pt

Abstract: In this paper we reflect about the liquid times we live in and its implications in the teaching and learning in universities. The technological realities take place at a furious pace that turns novelty into an ephemeral thing in space and time. We are always runing, not always knowing where to go, if we want to go or get there. The Internet access is uneven and reinforces previous existent inequalities. In teaching using technology, these issues are hardly considered, and the technocratic discourse is multiplied. In cases of institutionalized and conventional elearning processes that use learning management platforms (aka LMS), these issues are obliterated, mimicking a formal education and an obsolete disciplinary compartmentalization of knowledge. The e-portfolio seems to be an alternative to these platforms. If computers are seen as machines of communication rather than representation, it is possible to think in truly *ennovative* ways of learning and teaching.

Keywords: elearning, learning management systems, ePortfolios, higher education

THE WORLD IN WHICH WE LIVE IN

Cutting edge means the razor's edge, ie, the first cutting, the part of the knife that first comes into contact with the object to be cut. We have a technological artifact that is operated by a human subject on an object (which is expected not to be human!). The term was originated in the fifties (Dictionary.com, 2009b) in the anglo-saxonic world, in a context of great scientific and technological development (application of scientific knowledge). The term cutting edge applies to advanced technology and the expression is close to the concept of state of the art, the most advanced technology that is known and done, in a given area at any given time. The term is close to the concept of avant-garde which is more applied to cultural and artistic manifestations.

The term bidonville also appears in the fifties (Dictionary.com, 2009a) and literally means slum, poor construction of housing in major cities. It means, as reality and concept an unplanned urban organization, subject to the constraints that are put to the people who build it, always according to the most basic needs of survival, that will determine its existence.

Languages are alive and their speakers re-invent the words in accordance with the realities they live. The terms cutting edge and bidonville come at a time of confidence and hope for a future of happiness and harmony for the human species and reflect realities that did not exist. This hope was based largely on the belief that scientific and technological progress would solve all the problems of humanity. But this progress was accompanied by slums and 'next door' extreme poverty, that sixty years later continues to grow and to which we are accustomed and have come to familiar terms, mediated by television, while we sit on a couch or on a table of a café when we read the newspaper. We should, however, remember what we wrote elsewhere:

> The comments we just made, either by its content, either by its brevity, could be interpreted as technophobes and neo-luddites. However, they are not. We grew up with technology and we greatly appreciate it: we look forward to the teleporter that will end the anachronistic airports, the same way as we await the automatic writing that will allow direct entry of thought! (Oliveira, 2004, p. 59)

The scientific and technological progress has brought undeniable benefits to our lives and no one dispenses them, neither the rich nor the poor who dream of access to them. All of our well-being is supported by technology. And of all technologies, the most insidious are, of course, information and communication technologies, known as ICT and of which the tic-tac sets the pace of global development.

Between these liquid times in which we live in (Zygmunt Baumann) and the strait-jacket of chronological time, the technological reality is building up at a stunning speed that turns novelty into a fleeting moment in space and time. We are always running, not exactly knowing where to go, if we want to go or get there. Runs the gazelle and runs the lion, as in the African poem written at the entrance of a factory in China (Friedmann, 2006, p. 162):

Event # 6
Offshoring - Running with gazelles, eating with lions.
(...)
In Africa, every morning a gazelle wakes up.
Knows she must run faster than the fastest lion or be killed.
Every morning a lion wakes up.
Knows he must run faster than the slowest gazelle,
or die of hunger.
It doesn't matter if you're a lion or a gazelle.
When the sun comes up, you better be running.

As stated by José Saramago (2009), there is a kind of machine that pushes us all in a direction not very clear but certainly a direction of unbridled and uncritical consumption, dominated by a *hegemonic culture* (Antonio Gramsci), based in reproduction mechanism, always imposed, but often hidden. Hints and imagines Saramago the possibility of all of those pushed by the dynamics of oppression making the opposite gesture and pushing the machine back, challenging the prevailing social apparatus. (Louis Althusser).

The Internet is integrated in this machine but, almost paradoxically, the machine is us (Wesch, 2009): we nourished it and teach it every day! Because invariably, despite the misleading promises of technological determinism, some of us participate and others are left out. Technological determinism sugests that technology can solve all problems, that only technology can solve problems. Thus technology gains a kind of soul, abstract, and becomes an entity with human qualities. The problem lies not in technology but in this perception of technology. It's clear that, at the moment, only science and technology can solve the problems that we have created with them.

The collective intelligence of Pierre Lévy (1997) has not been for all and the efforts made for equity are weak and diffuse. The world of technology is a mirror of the real world. It has no independent history, as it is the result of the creation of productive forces (Karl Marx).

The Internet realities

The global realities have changed a lot over the last twenty years, especially over the last ten years. This is mainly due to the development of information and communication technologies. The Internet supports globalization, but if the Internet ceased to exist from one day to the other, what would happen to globalization?

According to estimates of 2008, there are 6.710.029.070 people (IWS, 2009) throughout the world; 1.596.270.108 people use the Internet and, at March 31, 2009, its penetration rate was 23.08% (ibid.). Who are these people who use the Internet, how do they use it and where do they live?...

Who are these people and how they use the Internet we do not know. We do know where they live, by geographic regions, and figure 1 illustrates it.

Internet Users in the World by Geographic Regions

Region	Millions of Users
Asia	657.2
Europe	393.4
North America	251.3
Latin America / Caribbean	173.6
Africa	54.2
Middle East	45.9
Oceania / Australia	20.8
Source: Internet World Stats - www.internetworldstats.com/stats.htm
Estimated Internet users are 1,596,270,108 for March 31, 2009
Copyright © 2009, Miniwatts Marketing Group

Figure 1: Users of Internet throughout the world, by geographical regions (IWS, 2009)

What do these numbers tell us? The obvious is that in Asia there are more people than in other continents and that Europe appears to be the continent where there are better living conditions and therefore easier access to the internet.

However, considering the penetration rate, ie, the number of users relatively to the number of people, the *statistical facts* change substantially, despite their reading being more or less obvious (Figure 2).

World Internet Penetration Rates by Geographic Regions

Region	Penetration Rate
North America	74.4%
Oceania / Australia	60.4%
Europe	48.9%
Latin America / Caribbean	29.9%
Middle East	23.3%
Asia	17.4%
Africa	5.6%
World, Avg.	23.8%

Source: Internet World Stats - www.internetworldststs.com/stats.htm
Penetration Rates are based on a world population of 6,710,029,070
and 1,596,270,108 estimated Internet users for March, 2009.
Copyright © 2009, Miniwatts Marketing Group

Figure 2: Penetration rate of the Internet worldwide, by geographical regions (IWS, 2009).

The position in the *graded list* of continents changes dramatically and highlights the issue of access to equipments and services, which, as we all know and sometimes seem to forget, reflects the living conditions of populations, the level of consumption and the GDP of the countries that integrate these continents. Please note that the superficial analysis made about these statistics - interpreted by the statistical methodology itself - just looks at the geographic regions and not countries, and within these social groups, social classes.

In summary, access to the Internet is not for everyone. And access is not guaranteed to improve the living conditions of populations, human happiness or better and effective learning, understanding effectiveness in education as learning more and better (know how to better apply what has been learned).

And in Portugal? According to the same source (IWS, 2009), on June 30, 2009 almost half the population used the Internet (see Table 1).

Table 1: Internet use in European counties with a population of around 10 millions of inhabitants (IWS, 2009, selected and adapted)

Country	Population (2009 Estimation)	Internet users, last data	% Population (Penetration)	Users growth (2000-2009)
Belgium	10,414,336	7,006,400	67.3 %	250.3 %
Czech Republic	10,211,904	4,991,300	48.9 %	399.1 %
Greece	10,737,428	4,932,495	45.9 %	392.2 %
Portugal	10,707,924	4,450,800	41.6 %	78.0 %
Sweden	9,059,651	7,295,200	80.5 %	80.2 %

If, in one hand, we still do not know who uses and how they use, in the other hand, we learn that for European countries with a population similar to Portugal (around 10 million), the position in the list is similar to the one of Greece and the Czech Republic, and yet lower. For two of the countries considered more developed (Belgium and Sweden), the distance is considerably amplified, allowing us to ask to what extent the investments made by the Portugal governments in this area over the last twenty years have been appropriate. This, assuming that, internationally and in the context of globalization, the use of internet is considered an indicator and factor of development.

SOME MISCONCEPTIONS ABOUT E-LEARNING IN UNIVERSITIES

The misconceptions about the purposes of the university and its rationale multiplying themselves, discrediting the utopia of a public university devoted to the creation, dissemination and knowledge transfer. On one hand, we continue to stress out and to value the research dimension asked of a university professor, demanding, at the same time, to use their time in distance training, fulfilling tutoring functions, almost impossible to accomplish by the number students to keep up with. Doing distance education requires thinking this modality in accordance and organizing the processes so that it can be done with considerable numbers of students.

On the other hand, the knowledge accumulated by generations of educators is, too often, runned over, and methods and strategies of teaching centered in the student are re-invented. What we see is, unfortunately, and in excess, the educational setbacks: lack of experimental and experiential learning; disciplinary clipping too tight for the realities in which we live in; observance of conservative teaching methods, completely anachronistic, as the lecture (magister dixit) as the unique and credible model of transmission of content.

In the case of institutionalized and conventional e-learning processes, that use learning management platforms (aka LMS, Learning Management Systems), the issues refered above are obliterated, as these platforms mimic a formal educational structure and an obsolete, tight and exclusive disciplinary compartmentalization of knowledge.

About LMS

The LMS reflects the rigid curriculum of training courses that are offered by universities and do not propose nor interdisciplinarity or transdisciplinarity, or collective building of a program. Each discipline or curricular unit (as the name itself indicates), is sovereign, independent, has a defined territory and borders. For this to be operationalized, these systems can only be cryptic: the teacher needs to request access to their administrative department, the student needs to have payed his/her fee, the interface needs to be decoded. The teacher dictates, a priori, what is done, how it's done and when. From a pedagogical and didactic perspective, the great advantage of these systems, it is said, is control. The students learning control by quantifying their participation: how many times they entered the system, how long they remained there, how many works they delivered, how many participations they left recorded in forums and chats. These elements are transformed in elements of assessment of learning, in addition to the work done and to exams. They do not seem to provide evidence of learning outcomes or knowledge construction.

It is assumed that these platforms replace presential classrooms since they compromise synchronous and asynchronous communication tools. This is accurate, if we think in a context of distance learning scenarios. In situations of presential or mixed teaching (b-learning), these tools lose a lot of their interest, since they will never be better than presential communication. They do present themselves as alternatives to face to face communication (the nearest being videoconference) and even serve as valuable resources when presential communication is not possible. But here we face, as aforesaid, a situation of distance learning, and it's important to distinguish, conceptually, the terms education and teaching – education is a process of training and transformation of the individual, not confined to formal processes of teaching and learning taking place in universities, intended to qualify students in specific skills and knowledge (translated in degrees). Education exists in universities and in society: education serves the personal development of each and everyone of us allowing civility and cordial relationships among individuals. The concept of education can be divided into multiple variants but it is impossible to be confounded with the concept of teaching.

One of the current ideas about the advantages of LMS is that they provide learning opportunities anywhere at any given time. The famous numerical expressions 24/24, 7 / 7 ... These two expressions are, in our opinion, a mistake and a fallacy, that resemble an advertising speech embroiled in a propaganda speech. Try to fill the famous wheel of time, used in training sessions on time management. Draw a circle and imagine that it represents the 24 hours that constitute a day. It will be filled with our occupations, starting with the most basic as sleeping, eating, personal hygiene, dislocations, until we get to professional duties or study ... With the completion of this exercise, it becomes easier to understand both how we use our time and become aware of the reasons that lead to the inevitable acceleration of people's lives. This means that time is not completely elastic.

Being able to learn anytime, anywhere, is a nice idea to tiller! But, in practice, it needs to be accounted for in people's lives. If before we needed time to study, nowadays this time is also needed. The Internet can break barriers of space but not of time. We can study at home, not spending time traveling, but we really need that time available to do so.

The mere possibility of being able to learn in a 24/24, 7 / 7 system does not guarantee that anyone and everyone can study and, in some way, improve their living conditions.

About e-portfolios

The Internet closes in itself a potential of success and impact in the ways of learning and teaching: serves the distribution, communication and intervention / participation, particularly with Web 2.0 technologies (forget about Web 3.0 or 4.0 and the trend of versions for everything), allowing to overcome the difficulties of access, a real participation.

This potential is based on five ideas that intertwine: the idea of fractal, representing what is and is not immediately visible and knowable; serendipity or the ability to make fortunate discoveries, apparently by accident, considered today as a special way of creativity, or one of many techniques for developing the creative potential of an adult, combining patience, intelligence and sense of observation; the theory of chaos, which, in Physics and Mathematics, is the hypothesis that explains the function of complex and dynamic systems - some specific results are caused by the action and interaction of elements in almost random ways - and that tells us that what people think happened randomly is, in fact, a phenomenon that can be represented by equations; storytelling, or the art of telling stories, a form of art inherent to the human language and to the human condition and, finally, the idea of collective intelligence, coined by Pierre Lévy (1997), which is embodied in the statement by McLuhan (1964) concerning the age of electricity, the final phase of the extensions of humankind, the technological simulation of consciousness, in which the creative process of knowledge is collectively and corporately extended to the whole human society.

These five ideas go hand in hand with the concept of e-portfolio, emerging as a learning technology that can and should operate as a personal space of archiving and management of personal information, such as 'virtual office' (Oliveira, 2004, p. 224) . The Internet was structured, so far, around objects, documents and, in a recent proposal - The Internet Manifesto of Subjects (Eifel, 2009) - it is proposed to be structured around subjects / individuals / people.

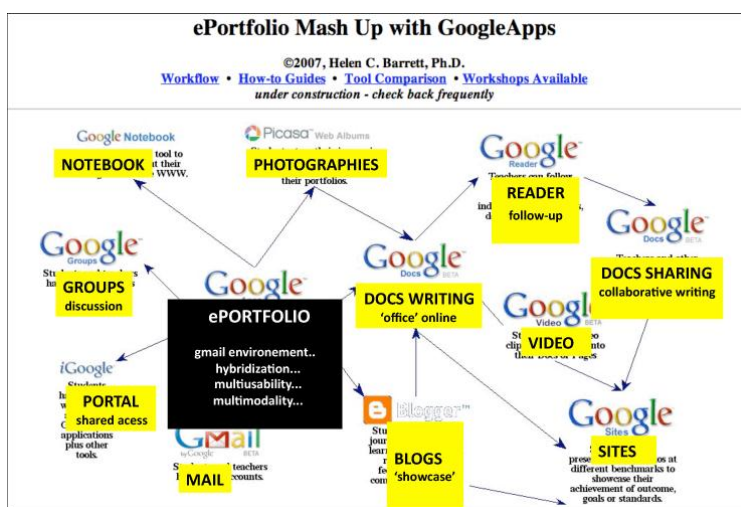
The portfolio belongs to the individual! An e-portfolio is a documents and file manager of a person, consisting of files (compilation of documents), views (representation of documents) and services (document exploitation). There are no open e-portfolio tools (except Elgg, Eduspaces nowadays) but there are free tools, although commercial, which allows to build them (figure 3). This is part of the business in the Google enterprise. The Google integrated tools allows us to imagine how an e-portfolio can become.


Figure 3: The rationale behind the e-portfolio (adapted from Barrett, 2007 and interpreted)

As we said in another context:

> We still need alternative platforms to these learning management platforms. Probably, e-portfolios platforms that can be used - guaranteed and given credibility - by public institutions. (Paraskeva and Oliveira, 2008, p. 14).

We entrust our money to banks and our personal, financial and health data to the state. Universities could well be true custodians of our learning and our collective sharing. Universities gather the expertise, know how and the necessary conditions to do so and to grant us the file and management of our lifelong learning.

The OpenCourseWare

Following this logic, is all the more important the project OpenCourseWare (OCW) of the MIT (Massachusetts Institute of Technology, http://ocw.mit.edu), which, ten years ago, published openly, the materials used in their courses. In a similar way, it is already possible to access various courses in various areas, in Portuguese (eg http://www.universia.com.br/mit/). As a complement, MIT also has a channel on YouTube, which offers videos of lectures, speeches, interviews, discussions, providing access to specialists and theoretical interventions of high quality. It is clearly possible to self learn through these open courses. There will be no human contact, peer and teachers interactions and no certification. That means that these dissemination processes contribute to the prestige of the institutions and do not withdraw its economic gains. Only by attending the institution can one have access to the certification of knowledge and skills.

We believe that this approach really complements the idea of e-portfolio. Effective distribution systems, such as these, repositories of scientific literature and of contents of educational intent, coupled with the possibilities of communication and management of portfolios in a model of social network, are likely to enable better and more advanced processes of teaching and learning.

CLOSING REMARKS

We are the spider! And we weave the web. Provided that the access discrimination is overcome, with social software systems, increasingly embodying the public square of the new generations (Rasco, 2008), we can truly think in really ennovative ways — which are different from innovative for its unexpected and self-controlled emergence (see Bonami and Garant, 1996) — of learning and teaching, building a society where everyone can participate.

We must use cutting edge ICT to re-invent these forms and not to perpetuate the bidonville. To reproduce dusty models does not help creativity. The Internet enables us to glimpse new scenarios impossible to imagine before and of anarchist inspiration. Trying to entrap it could never return good outcomes. Cryptic and closed systems generate exclusion, just as in life before the internet and in life with the internet.

Abstract: After a century marked by the prominence of the state organization, distribution and regulation of education, particularly with the implementation and consolidation of obligatory education, the profound changes that have permeated society contributed to challenge the current state monopoly in terms of public education and the coming of new forms and local schooling. In this process, new technologies have had a key role, allowing to break the physical boundaries and structural taxes for schools. Based on the mapping of relations established between the private sphere - home schooling - and the public sphere - education in institutions – and analysis of the possibilities of these spaces coexist in society, central aim of this paper is to discuss the importance of this educational phenomenon, in particular about the progressive tendencies of learning outside educational institutions and the contributions that the new technologies can offer in this process.

Keywords: Homeschooling, Learning without an educational institution, New Technologies

EDUCATION AT HOME AND AT SCHOOL

The planctarization of human life is a reality today. Morgado (2004, p.110) says it is a social and cultural fact that propagates at an unstoppable speed, primarily through two means: a "triad of science-technology-economy", regarded by many as "the faith of our time "and that" has changed as brain as heart of contemporary society and the media, which diffuse, continuous and effective new ways of thinking and new cultures, very different from those in which we were socialized".

According to the author (ibid.), we live in a world that changes quickly, which has changed the notions of space and time, inundated with knowledge and information that are renewed at an impressive rate and that "appeals more at each time to creativity, innovation and retraining, but where education has not been able to prove itself nor as a public service distributed equitably, neither to accept itself as a formula of compensating inequalities."

It can be stated that changes supervened technological innovations that occurred since the last decades of the twentieth century profoundly changed some aspects of contemporary society, including access and speed in obtaining the knowledge, using, especially information networks available in web. The advent of new technologies in education, in turn, has brought many opportunities to school and school instituted, but also helped to break the confines of this formal education, allowing thoughts turned beyond the borders before the contained space (physical) school.

In a move that, as a simplistic way, it outlines quite obvious, he turned to think of education as a process that could occur in the home, dealing with different classifications from the countries where such practices are beginning to be discussed and implemented. Thus, the education conducted in the home environment becomes known as "home education", "home schooling", "home education", "home schooling or homeschooling, word that the United States of America has to name this new possibility education.

Although homeschooling is the name most often used to refer to this alleged form of education in the household, their translation into Portuguese, can not be taken literally, because it means home schooling, but the processes schooling that occur in private spaces under the responsibility of family members and, so far, without the direct interference of the state.

In addition, the homeschooling on the American model, in general, it is a broader conception of education than just teaching content because the content of a search process of teaching in a more "teacher", related to different perceptions of world, beliefs and ideologies of families who opt for this practice, and is even in the literature on the subject, more rare, the terminology home education.

Register that, among the depositions taken on the matter, is who label this process as "education from the house." This nomenclature stems from the idea, the applicant between the person performing the home education of children and young people in their process of teaching, spend less time at home than the regular students stay in school, because education in the home would include numerous activities outside the home environment, such as those in school are called extra-curricular activities.

Indeed, the nomenclature used to describe the desired new mode of education in Portuguese-speaking countries, particularly in Brazil and Portugal is still not consolidated and are variations of the same terminology in legislation and official documents of the countries in focus. However, when it comes to the education that occurs in the home of students, parents or teachers who contracted the education, they find themselves practices of what is conventionally known as homeschooling, considering that this type of home schooling in the United States America, much can be accomplished by parents as they can hire teachers for those subjects that do not dominate, there are even websites available that registering teachers for this purpose.

In the study in question, we chose the nomenclature of education at home, when we refer to the broader concept and the possibilities to get education done in the home, as well as the specific terminology used by the authors attributed in texts or documents examined.

However, to understand the design attributed to the terminology used to check each one of the words used to refer to the educational process, as "education" and "school", seeking the genesis of his assignment as synonyms, which occurs as the education becomes a prerogative of the school and will be, since closely related to that, being taken as synonymous with one another and, in other words, formal education came to be understood as a process of exclusivity of the school through the school established by various systems of public and private education, which gained hegemony over the offer of education, its seal, legality, assessment and certification.

Thus, while education and school are words commonly used as synonyms, concepts refer to quite different processes, not only by temporal origin that separate them, but mainly because it is considered an infinitely wider than the other, being education the main goal of the school.

The term education is used to describe the process of training and instruction for children, youth and adults, is a process that can occur throughout life. Moreover, education as a process of teaching is characterized by having been present in societies since ancient times, occurring most diverse ways, in different spaces, both informally and through a previous organization. When the educational processes become more complex, clinging to the status of a scientific who set up the sciences and their scope, were set up specific locations for the transmission of teachings, called schools, high schools or colleges, each with their specific. For children, the schools in their infancy had also, in certain contexts, guard duty, to protect the disadvantaged children.

Koselleck (1992) argues that concepts have a history and that are linked to a specific context on which can also act, thereby making possible the temporal variation of the concept. From this perspective, stems from its unique character related to the time of use. So we can assume three times / dimensions of the genesis of the modern concept of education, with reference to the Luso-Brazilian world. The first where the concept of education is unrelated to any formal space designed solely for that purpose. The second it relates to school undeniably, taking on the nickname of "informal" when releasing it, that is, education is only "formal" when held in the school. And the present moment, in which education starts to be thought so disconnected from school, without losing the formality afforded to it as idealizing the processes of teaching and learning.

Education, as well as a broader process that was not always tied to the school, with other spaces considered legitimate for it to happen. However, from the late nineteenth century, now, little by little, becoming an exclusive activity of the school that the family shared with only those aspects of education, taking responsibility, in full, the instructional aspects. This association of education to school consolidated the hegemonic model of the twentieth century, which served well the needs of current industrialization, capitalism and the modernization of emerging companies with multiple creations and inventions of the last century.

Once established the close link between education and schooling, the processes of teaching and learning have become their exclusive competence, using for this, plans, methods, resources and procedures adequate to its collective format, and by age groups.

While some families get in actuality, to consider the possibility of educating their children and relatives in the household, this terminology needs to incorporate new meanings, able to treat the meaning and limits of each term. Thus, education resumes its broadest conception, is viewed as the integral process of teaching and learning beyond the confines of the school, which in turn is understood as the institution offering formal education, based on a system enrollment codes and standards themselves assigned to subjects in stages, which must be met for moving to the next.

Nevertheless, in many countries, the school is recognized as the only legitimate place for the provision of formal education, while in others, formal education is authorized to be obtained at home through a set of tools that are available to Internet the specific manuals for this purpose is a process of education which, though not acquired in school, but that amounts established by the school.

In the case of countries where the domestic space is accepted for the schooling of children and youth, then we can distinguish two concepts that will refer to education as the acquisition of knowledge, experimentation and knowledge of the construction of knowledge: education in schools and education at home, both formalized, since they are officers and status. Homeschooling allowed and regulated in many states is an example of such officers, for which there are elaborated the statutes and rules of evaluation and certification.

Therefore, educating at home this is the case in which the teaching on the knowledge needed to schooling, is performed exclusively in the domestic context, for the family group, characterized by occur outside the official educational institutions, both public and private.

Accordingly, the first step so they can understand the concepts related to education at home, is the definitive separation of the concepts of education and school forged narrowly over at least a century of exclusive hegemony over the school educational processes. Separate them conceptually is no easy task, not the strict meaning of each, in this new context that is already a reality in many countries, but the implicit meaning that load-related tacit understanding that there can be no school education and the belief in losses, and the numerous implications for successful unschooling society.

Although education in the home already has today, many adherents, spread across several countries, organized communities, and especially theorists and researchers to address this issue, there is also a ratio greater than or equal, those who strongly condemn such practices, whereas schooling, with their systems in place, was an achievement of the last century that has brought undeniable progress for society and any alternative that breaks with its format is unacceptable on the grounds that it is necessary to improve school quality, but in no event, unschoolers society.

However, under the excuse of freedom as a basic principle of human rights and freedom of choice as a right of parents to educate their children, hangs up a duel between these two streams, which in addition to the political and pedagogical involved, one can not disregard the prospect of education at home, back to the educational scene as a real possibility, as information technology and communication available closer knowledge of the subject and make its intermediation sometimes unnecessary, breaking with the physical boundaries of school for the concreteness of the process of schooling.

With respect to the supporters of education movement in the house, we can affirm that gain popularity in the early 1980s, especially in the United States of America, and spread across the continents, taking up records in the following decades, experience home education worldwide. According to data presented by Ray (2005, p. 8) in its Worldwide guide to homeschooling, facts and stats on the benefits of homeschooling, in 2002, there would be families educating their children at home in the United States, Canada, Mexico, Wales, England, Germany, Poland, Switzerland, Japan, Australia and South Africa In 2010 these figures amount to more than 2 million children and young people undergoing education at home only in the United States, where homeschooling is legal support to be offered in 50 states, although in some, with very restrictive rules.

Also composed of a different stream, which is nomenclature used unschooling (objection school), or "unschooling" in the strictest sense, the movement would continue to grow significantly, according to the National Home Education Research Institute, author of several research and monitoring analysis of this phenomenon at international level. To do this, could be considered for several reasons, which would point in common, in most cases, opposition to the laws and the system of compulsory schooling and current.

Families who turn to education in the home, so would normally be too different from seeking a training offered by schools, whether for religious, philosophical, contextual, or special circumstances. Yet this perspective, the discourse of proponents of education in the home brings the theoretical arguments based on unschooling, as Ivan Illich and John Holt. Illich wrote Deschooling society (1973) proposed the unschooling of society and said to avoid that government funds were used in this order: the schooling system, destabilizing it, as had been done in the separation of church and state. According to Illich (in Farenga & Holt, 2003, p. 60) ought to amend the Constitution to prohibit the establishment of education. John Holt, in turn, spent the remaining years of his life trying to find ways to create these changes, but realized that most people would never agree to stop funding to government schools, and sought other ways to move toward goal of "empowering" or prepare people to grow up without schooling. For schools it possessed sufficient power "to cause mental and physical pain to children, to threaten them, frighten them and humiliate them" (Holt, 1976, p. 204).

For more involved in the movement, homeschooling is compared to a revolution, as suggested by Lyman in his book The Homeschooling Revolution (2000). The author examines what he calls "the big differences

between homeschooling and public school and homeschooling characterizes as a" popular movement by dissident parents, educators who are teaching their children to read and write at the kitchen table" (Lyman, 2000, p. 115). She said those parents were doing what is considered, so far, an acceptable idea of the counterculture: "committed parents have achieved their goals without much applause and without a penny of government funding." Lyman (ibid., p. 20) describes public education as a "system of keeping a monopoly based on well-organized, financed by confiscatory taxes." It also states that public school children have little or no control over your time or social contacts, and must undergo a series of "draconian rules" state-mandated courses, attendance requirements and groupings by age, with unable to escape the slow indoctrination, or the effect of poorly trained teachers, or rude, and violence from colleagues. Lyman (ibid., p. 23) cites research that helped popularize the modern homeschooling movement, conducted by Raymond Moore and John Holt, in which Holt saw schools as places that produce obedient citizens, boring and unprepared. The author (Lyman, 2000, p. 87) shows that, with respect to the results in the cases studied, regardless of race or family income, homeschooled children obtained higher scores on standardized tests than their public school peers.

It may be seen visiting the numerous sites of homeschooling available on the Internet and as stated by several authors, who are more advantaged social classes who have sought to homeschooling. From this perspective, the education movement in the house is also characterized by a reaction to school sometimes, regardless of quality conditions presented, although the defense speech of homeschooling has used as a recurrent argument, to expose the weaknesses and difficulties encountered in public school. However, this discourse can perhaps be related to the opportunities as measured by "common sense" to advocate for their purposes, than in reality will be their choice of families to homeschooling.

PERSPECTIVES ON HOME SCHOOLING IN THE FACE OF NEW TECHNOLOGIES

According Fernandes (2005), recognition of the school is established, especially after World War II, as factor of economic development through human resources training. The allocation of this function led to its categorization as an obligation of the welfare state and social rights as an individual.

> Since then the school as a forum for formal education is seen "sometimes with great optimism now on in disbelief." In either case, however, she continued to fill most of the concerns in terms of research and theoretical reflection. Fernandes (ibid.) adds:
> The problems relating to education policy - the supply and demand for school social, issues arising from the democratization of education and the operation of educational institutions, public or private, to the difficulties of adaptation of young people to school, seeking answers to the what was called the "crisis" or "questioning" of the school - the quest of solution strategies for these and other problems through the formulation of new proposals pedagogical-didactic or demand for new institutional leaders, among many topics that could evoke have always turned around in the establishment of the school. In recent decades, however, the academic institution, public or private, seems to have lost its leading role, if not its exclusivity in this discussion. The special case of the United States in this regard is very significant. The crisis of educational policies and outlined the difficulties that confront the schools seem to lead to the upgrading of teaching modalities that had lost its historical validity, such as home-schooling. The desire on the part of families, educational efficiency, permanence of values and physical security, takes recourse to the education within the home, which is reinforced by the current provision of computer information sources (p.4).

The optimism that was sustaining the belief in education has, in recent decades, given rise to severe criticism of the school, whose malfunction, unavailability of access, production failures, innocuous restructuring, among others, are questioning their purpose and take intellectual different nationalities to turn to a discussion about the future of the school.

Skeptical of acclaimed reforms they propose to remedy the deficiencies of the school system, increasingly, the model of compulsory education is questioned and alternative formulations that arise based on the opportunities arising from the advancement and mastery of new technologies, allows thinking in education outside the school, is, the many perspectives that are needed, among them to recognize the house again, as a place of education.

In a world constantly buffeted by crises, in which the fear of violence in collective spaces is becoming more intense, many things have contributed to the demystification of the school as the only suitable place for learning. Moreover, the successes that have occurred in the experiences of distance education, whose private space, home or work, becomes the locus of educational action challenging the monopoly of school

environments as well as reinforce the need to articulate effectively the possibilities that arise with new technologies for formal education.

According to Vasconcelos (2006, p. 10), it is not just a methodological conflicts, "but a process that has previously occurred and where the context of an era, was crucial to the survival of an education system over another." Likewise, today it is possible that once again the social changes, which also require to be reviewed the collective spaces of education in a more periodic structure of adapting to complex social teaching.

Durkheim (2001) in the first decades of the twentieth century had already pointed out that:

> Indeed, education, use in a given society and considered at a particular moment in its evolution, is a set of practices, ways of doing, ways that facts are clearly defined and have the same reality as other social facts. There are, as long believed, combinations more or less arbitrary and artificial, which owe their existence only to the capricious influence of wills always contingent. They are, by contrast, true social institutions. It is impossible to make a company has at any given time, a different education system than the one which is involved in its structure, the same way that it is impossible to a living organism and other agencies have other functions than those who are involved in its constitution (p.73).

The model of education / school practiced, today, can not be claimed as the most unique and exclusive that is implicated in the current social structure. The rapid changes in society, itself suffers with the advent of new technologies, transforming not only everyday behavior, but also a series of principles and rituals that little by little, become unnecessary and obsolete. The same occurs within the school environment sometimes completely outdated before their social environment.

Education begins a new concept linked to the contemporary in which lays down, in which physical boundaries are no longer needed to educate, can not even hold their practices, giving the new education concepts and settings that allow legitimate, not only for their revision concept, but this new option to allow society. Thus, new patterns of behavior that could bring profound changes in the educational processes, from the collective to the individual, namely the linear to the multiplicity of knowledge guided by the interests, through the redefinition of knowledge and its application to the formation of a new format free of pre-established concepts, such as age, maturity, skills, finally, creating endless possibilities.

From this perspective, it is likely that the home education constitutes a form of alternative education to families under the influence of specific conditions, recourse when, among other reasons, the school does not reach the expectations of their demands. To this end, the problem to be faced by current educational policy, not to establish or restore conditions of competition between these different modalities, but the possibility to upgrade the training instances as the house, they can through various methodologies, including they distance education, and place themselves on equal terms and qualitatively, among the options that are presented to families and communities.

Currently, either by barriers of location, so for fear that parents have to put their children in existing schools, by prejudice, health issues, problems increasingly recurring violence and discipline, high costs, among other assumptions, the What you see is an increasing demand from families who decide to teach your children without them attend school. Although the number of such households in the first decade of this century, is not significant enough to mean a possibility of unschooling society, it already shows the beginning of a movement that becomes, again, the choice of home or school a reality among some societies, whose laws do not provide for compulsory education or allow different educational experiences.

Unlike the domestic education for the elite eight hundred in the domestic education, today, covers several categories of society, given the different motivations, ranging from religious views, philosophical, until conditions on the lived context, the special needs of students and the momentary circumstances that prevent parents from placing their children in school.

Moreover, such practices are similar to other features of society called "postmodern", as isolate and form independent groups, led by the private and under the strict liability, structuring and monitoring, decentralized in their actions, methods, contents and procedures, so that each family is solely responsible for the education of their children, relatives, or aggregates.

Given the importance that technological advances have acquired in everyday life, education certainly could not be oblivious to the profound changes resulting from new relationships established from the advent of personal computers, cyberculture, information technology and communication. The model of schooling forged in the nineteenth century, under the tools that were available to teach in that space / time, certainly would face in this new century, the challenges of a new model of knowledge acquisition that dispenses not only bounded spaces for this Last, but specific forms of accumulation of knowledge which require

prerequisites and a linear summation of learning. The technology allowed each subject before his own machine to become an agent of his learning, making choices, selecting content, creating his own method. From the ever so natural understanding of the possibilities of knowledge based on the online networks, the educational question appears on the face of challenge even when the state able to control or interfere with existing educational practices, as has been done through the schools, deciding, hiring, overseeing and acting for the education of children and youth.

Moreover, the weakening of the state, its shrinkage and disencumber with the supply, implementation and monitoring of services can have serious consequences to the social and political force. For the most optimistic, would be ideal illichtiano, who saw the educational system as a result of the industrial revolution of the nineteenth century, and therefore, based on their models of factories, coercive, hierarchical, and targeted measures, in addition to fragment knowledge by separating students according to age, to tame them and make them understand how natural inequalities.

The concept of unschooling refers, particularly, the characteristics of the school that is supposed to act as a repressive institution's reproductive and social order, bringing more problems than solutions. However, the sense of the word unschooling homeschooling in the context of current times is more accustomed to the idea that society Unschoolers of Illich can now be achieved through learning networks, through the web tools, and the many existing technical possibilities.

However, the concept of unschooling also brings many dangers implicit. According to the official website of the National Institute of Educational Studies Teixeira (INEP), an agency within the Ministry of Education of Brazil (MEC), unschooling means:

> Deletion of the school institution. Movement that fights to formal education by giving it enforcement functions, and which calls for free media education and unconventional. According to Ivan Illich, schools should be abolished because: 1. She is compulsory 2. is oriented credentials, which, by its formalism, replacing their own learning and determine unfairly rewards and the positions of students in society, for the rest of their lives 3. its curriculum is mandatory, rather than allow free experimentation by the students; 4. it arbitrarily separates children by age, preventing them to come together spontaneously as their mutual interests and abilities, 5. is a hierarchical top-down driven, with the student in the school fund. (Deschooling Society).

When you think the reverse of each of these "repressive functions" that school would have, we do not think that domestic education, in a way that is being established, which is allowed, would bring major changes on the profile of education. Indeed, the challenge takes place in the collective aspect it is society without schools would have to seek other ways to promote the socialization of individuals, besides having to find other ways to reach everyone on the permanence of the social pact between the state and individuals.

Maybe break with this relationship between all compulsory subjects and the school will be a greater risk than those already indicated by the neo-liberal project of reform. Even more serious than disencumber state for the education of people is the fact that other areas of ideological wealth would take this place, these areas perhaps more difficult than the school, being watched, followed and even perceived, as well as targeted to interests that could certainly not be the welfare of the community.

Anyway, reality requires a placement, because it becomes increasingly impossible to be indifferent to the possibilities that new technologies bring to education and especially for education at home.

The Brazilian education, as well as the Portuguese, was until this day, for over a century, constantly referred to the state government (Vasconcelos, 2009), and break these relationships establish other means, acceptable and credible, This can not happen, but as a slow movement that will, bit by bit, changing the existing paradigm, just as occurred in the transition from education to home schooling compulsory.

At that time, the nineteenth century, the dispute between these two areas reflected their own dispute over centralization, unification and merger of state policies, but mean and what now?

A century after the undisputed supremacy in the legitimacy of the school to educate and teach, given the technological innovations that are fast and radically transforming, with information being taken at any point and no more need for space to concentrate such information physically, with virtuality of knowledge and the possibility of appropriating it at any time, some issues require consideration, including the prospects that are opening up home in this new context, as an area of education.

The analysis of this and attempt to read the "shadows" of the future is no easy task, much less, that can be done without a very high degree of risk. However, for now, the following reflection is possible, as proposed by Vasconcelos (2005, p. 190): is the nineteenth century can be considered the home of their masters and by major occupation of the time they were present in education, the twentieth century was undoubtedly the

century of the school established for education. However, we can say is that the same will happen in the coming century? You can not rehabilitate the home place of education and instruction through technology already available?

101 - Beyond to the "*Deficit of Meaning*" in Science Teaching: An Experience of Tutoring at the Open University of Brazil

Elizandra Dias

Student of Pos Graduate Program in Geography, Geosciences Institute, Federal University of Bahia, Brazil.
zandradias@hotmail.com

Abstract: The educator's perspective as the one who militates alone "… inside his own desert" as well pointed by Gallo (2008:73) when he defined which attitude is required of us, educators, in order to educate, sends me to my own teaching experience, lived in contemporary Brazilian reality and deeply affected by it. According to Gallo, it is necessary: "To educate with the fury and the joy of a dog that digs his hole. Educate by excavating the present, to militate in world's misery, from inside of our own desert". This article is precisely about this: excavate the present from my impressions as tutor of distance education to reflect on how we conceive and teach natural sciences to teachers still in training through distance education on a Virtual Environment of Learning under the seal of Open University of Brazil. It is about how or in which way we contribute to overcome the "deficit of meaning" related to the teaching of School Science during two disciplines that had as initial curricular purpose the teaching of a plural, complex and better assimilated knowledge in an interdisciplinary way. With this aim, a focus that encompasses, on one side, the relation between the Science, the technology, the society and the Environment – CTSA focus – and the resources that come from New Information and Communication Technologies – ICT's – and by another, a significant scientific-technological literacy necessary to the comprehension of actual social-environmental problems and their consequent overcome were used as promoters of a shared mediation that fruits in this study.

Me: "Explain to me this thing of '... turning back to the west we have got ahead the north on the right and the south on the left'...".
Little girl: "Oh... I forgot it... This was the subject of last year...".
(Rubem Alves "Diálogo com uma menina de nove anos" *in* Do universo a jabuticaba 2010:43.)
"What makes human beings thinkers is the feeling that they are not yet perfectly confortable in the world"
(Fourez,1995:87)

An increasing demand for scientists and technicians was greatly aggravated since the last century, mainly in emerging countries like Brazil, which seek to consolidate its industrial base and enter the world market as commercial partners able to offer products with high technological value-added, instead of just appearing – on the international scenario – as suppliers of grains and raw materials. In this search for a place "in the sun" in the capitalist solar system, education takes, in brazilian public policies agenda, a place of prominence, becoming the object of a range of assumptions and intentions. The demand for teachers in general and, specially, for Science teachers, more capable and open to the social changes underway the so-called liquid Modernity (Bauman, 2001; Giddens, 1991) is a rising concern translated into didactical effort that unfolds in undergraduate courses, particularly, in those of Pedagogy.

The growing shortage of teachers in various disciplines considered scientific - chemistry, physics, mathematics ... – as if the others were not, the decreasing number of students that are available to invest in undergraduate courses focused on teaching, and the attempting to reinforce higher education in a country of continental territorial extension, led the Ministry of Education, through the National Fund for Development of Education – NFDE – to establish, in 2005, the Open University of Brazil, the OUB. A system created with the purpose of covering public universities in the three spheres of power – local, state and federal – mainly through Distance Education – DE – offering then didactical and technological support for both, the classrooms courses and the virtual courses, using for it the *Moodle* Platform, a Virtual Learning Environment – VLE - created as free software and main tool of OUB.

It is in OUB system that I have been working as tutor of distance education since 2009 in a Pedagogy course, specifically in two disciplines closely related to Science teaching, entitled: Natural Science I and II. It is from this experience that combines: the New Technologies of Information and Communication, the relationship

between Science, Technology, Society and Environment, the STSE focus, and a significant Scientific-Technological Literacy, STL, that this essay is born and in which I report the way we suggest, in a group of seven tutors and a teacher, to build together with the students, future teachers, a comprehension of scholar science capable to overcome common sense, cover the complexity of current socio-environmental problems and to supplant the relative deficit of meaning related with scientific knowledge.

The disciplines were divided in fifteen weeks each, during what were worked contents as: everyday knowledge *versus* scientific knowledge, common sense, interdisciplinarity, Environmental Education, Scientific Literacy and citizenship, civilization crisis, environmental crisis, sexuality and human body. The choice of this content did not omit in any way other contents of science curriculum, but it was mediated by the social, environmental and individual world of the student in question, connecting him to a social-critical dimension of his life, as a manner of trying to break up with a way of teaching that is discursive and strongly fixed on contents, which still very present in Pedagogy courses, privileging concepts that would allow an interdisciplinary approach and take part of the challenges faced by the students, some of which are already teaching in Elementary School and needing instrumental tools capable to inspire creative and functional initiatives of didactics and methodology. What we intend with the choice of this themes was to articulate concepts come from natural sciences – biology, physics, chemistry – with philosophical and pedagogical assumptions of education in sciences.

Therefore, the production and the consume of knowledge in sciences and in didactics of sciences, turn to scholar context its aspirations for renewal. What moves us is the fomentation to an initial academic training of teachers which is critical and reflexive in order to combat the reductionist view that, according to Auler and Delizoicov (2001) is characterized by belief in three myths: the technological determinism, the scientific superiority and the salvationist perspective.

In attempt to dispel such beliefs, we proposed to students the initial readings: Rodrigues (2009), Angotti (2002), Foures (1994), amongst others, which are able to lead them into a rupture with this idealized view of science as well to encourage them to reflect about their own scholar process, through a discussion forum entitled: "Memories and stories of science education", where many have found they have been educated in a technical and fragmentary perspective of scientific knowledge. To recognize in his own trajectory marks of a positivist education was the first step so that the student was aware that the STL must come from the world of meanings of the learners and not be imposed as an external empty of meaning. For Bybee: "Most educators agree that the purpose of scholar science is to help students to achieve higher levels of scientific literacy." (Bybee, 1995: 28).

So then, what would be the STL? Authors as Shen (1975), Lorenzetti (2001), Fourez (1994, 2006), Santos (2007), Bybee (1995) as much as Auler (2001) and Delizoicov (2001) – these last two, authors who integrate an extensive bibliography that appears in the already existent literature – talks about different approaches and perspectives contained into STL's concept. The reductionist, the expanded, the civic, the practical, the cultural, the functional, the conceptual-procedural and the multidimensional. Neither of these forms exhaust or exclude the other ones, I believe denominations are trying to realize what the process of STL is in a contemporary, complex and unequal society. A process that must take place continuously from an early age, beginning at scholar phase but that does not finish there. According to Laugksch (2000:94): "Many positions, descriptions and interpretations were integrated in a useful conceptual review of Scientific Literacy that highlights important aspects of this concept. This review, thus, products an ample understanding of various factors that contribute to the concept of Scientific Literacy and make clear the relationship between these factors, giving, then, rise to a more refined and focused conceptualization of Science Literacy".

And it was precisely by pursuing a more refined conception of STL that we explored the didactical possibilities offered by VLE, which, in this case, is the MOODLE platform, typical of DE as: movies, music and case studies. Some of this resources, explored through other forums, through wikis, always relating the STSE´s approach with a significant STL.

To this end, we decided to work with the concept of Life inside scholar science and not only in its biological dimension – that involves its evolutional, anatomical and functional character – but also its social character. It could be read in the summary of the week in question: "We have posted this week a text and two small videos that discuss the concept of life in biological and social dimensions. We thought this class could expand you understanding human being in its similarities and distinctions in relation to other living beings. Knowing the human being is to comprehend its animality and its humanity, it is to deal its complexity and its unity related to other beings, it is to situate it in universe, not separate it from him. And then here, it is worth bringing the ideas of Edgar Morin. To him, the human being is both inside and outside of nature." After this, the forum put the challenge of the week, wherein the learners were taken to discuss two basic questions:

"What human beings have in common with other live beings? What differentiates it from them and giver him complexity?"

This reflexive exercise may seem overly obvious, but it had the intent of arouse correlations that overcome common sense and it was just the obviousness of the answers that drew most attention in the forum and highlighted the lack of criticality necessary to the theme in discussion. Much of the course participants pointed just the classical distinction between men and animals as it is emphasized in sciences classes in elementary school. A student posted what would be repeated countless times by many others: "Men are born, grow, reproduce themselves and die such as animals and what makes us different from them is our capacity of reasoning!"

To supplant common sense is one of the challenges that STL puts to itself, of course we distinguish ourselves from other animals because we think, but none of the learners was capable to cite other skills of our unique mental faculty. Not even a mention to our capacity of producing culture was done or, to the fact that we are historical and social beings able to, not only interact with environment we live in, but also to be modified by it. We, human beings, do not just and simply born, live and reproduce ourselves on Earth and this is not the only similarity we have got with other animals. We, human beings, are the historical result of the permanent accumulation of knowledge, able to produce and reproduce constantly the means by which we become what Marx called "subjects of history". We are one of the uncountable forms that are part of what Life is, understanding it as a whole and a part at the same time is necessary when we think a STL that worries, firstly, with the construction of analytical processes and only in second place, worries about transmuting everyday concepts, daily concepts, into scientific concepts. A STL that aims to build a subject when, in fact, we are living the era of individuals.

The bank education so reported by Freire is constantly present in our elementary school, as a mark. Lasting remnant of a educational process based on the enumeration of contents and the absolute incorporation of the deficit of meaning towards the construction of scientific knowledge, that still continues today in the classrooms of a country that begins to pay attention to the fact that it does not have a population scientific and technologic literate, most of it, and even, at this moment, teachers enough and with sufficient dexterity to do it.

To teach sciences it is necessary not only knowing sciences but also knowing how to teach them, as Paulo Freire would say: "None knowledge is exempt from intention" (Freire, 1980:25). To evidence justly the political and historical character of scientific knowledge we proposed another moment of reflection to the course participants. This time, the concept approached was technology in "Technology for what and for whom?", the student should "work" on a techno-scientific innovation, evaluate its pros and cons and search ways of questioning this innovation in classroom. Lots of lesson plans, ideas and scripts emerged from this forum. Even technological innovations of past centuries were used as main theme of classrooms, sometimes in a creative way, sometimes in a extensive one. This is what demonstrates learner's comprehension about scientific knowledge's historicity.

Bizzo (2002), in a book about teacher´s formal education, entitled: "Sicence: Easy or Difficult?" points five specific keys to scientific knowledge, including the *conceptual independence* (Bizzo, 2002: 25) that, according to him, expresses the historical relationship of dependence between concepts and scientific theories. A theory, a general law or an analytical category of analysis does not come from a previously given knowledge or an everyday knowledge only, it is based on a later theory, scientific proved and that is what attests the historicity of scientific knowledge. "The scientific knowledge may be, perhaps, compared to a castle of cards, not as a reference to his consistency but to the interdependence of its parts. This means that, if a theory comes down, may others will be affected." (Bizzo, 2002:25).

To recognize scientific knowledge as historical, interdependent in its genesis and during its development, is to be capable of evaluate its concepts testing and applying them critically and continually, is to be able to comprehend, as these learners did, that technology is not a typical tool of contemporary days but the result of scientific knowledge historically built and interdependent itself that is experienced in contemporaneity.

It was proposed a work between History and Natural Science II at the end of the first semester, focused on interdisciplinary required by the teaching of scientific knowledge, many other tools of VLE were used adding didactical value to worked concepts, games, videos and as already mentioned even lyrics of music served the purposed of questioning the approached contents.

In some poles – almost all spread over Forest Zone and southern Minas Gerais, located in small towns up to 30.000 inhabitants – particular resources functioned very well, and some problematizations fruited. In some of them, the student´s answer was different. Not worse or better, but different, and in general, positive, in a perspective of rupture with the conception of a supposed science knowledge's superiority, demonstrating

many times the deconstruction of these students' ideologies and prejudices related to Science and its contents.

To question a scientific theme may be an interesting didactical resource. During the disciplines we developed many analysis and reflections, always intending to conduct the learning process of the future teacher toward the rupture with a crystallized vision of scholar Science, classificatory and taxonomic par excellence. We have tried to improve the existent skills developing new abilities so that they were able to propose, in the future, within their own classrooms, new forms of Science learning. We did that in many ways, often showing situations in other schools, seeking to foment reflections from the suggested texts in a way that didactical situations, related with scholar content, could emerge. But it is not our intention here to discuss each of the thirty weeks or the uncountable contents covered, just register this pedagogical experience, this tutoring, that occurred as a shared mediation, exemplifying some contents, seeking to bring to academic discussion of this event forms that, if not new, at least are more palpable in scientific education, for considerations and discussions.

mfcosta@fisica.uminho.pt

Abstract: Educational Robotics (ER) is increasingly used to boost student performance in several subjects, being reported successful attempts to introduce ER as a non-conventional way to help students in learning mathematics, sciences or even arts and to implement novel learning approaches, such as constructivism, project-based and problem-based learning. ER has been used to promote multidisciplinarity and collaborative work, to foster students' motivation, imagination, creativity and logical thinking.

However, available studies are mainly descriptive and qualitative. Indeed, fundamental questions, such as "Is ER a suitable tool for basic school students?" or "What are the contents/skills that can be taught/learned using ER?" remain largely unanswered. This paper proposes a methodology to conduct studies that provide an answer to those questions.

Our proposal has two distinct components: (*i*) the planning of a set of ER sessions to conduct with the students; (*ii*) validation instruments to apply, for quantitative and qualitative evaluation of ER as a pedagogical tool. An example is provided for subjects related to the concepts of multiplication/ division in 4th grade Mathematics.

Keywords: Educational Robotics, Problem Solving, Mathematics.

INTRODUCTION

In recent years, Educational Robotics (ER) has been increasingly used as a pedagogical tool to boost the performance of students in several subjects and age levels. Many authors report on successful attempts to introduce ER as a non-conventional way to help students in learning subjects such as mathematics, sciences or even arts and to enable technological education (Gura, 2007) and (Bers, 2008). Also, ER is a good way to implement novel learning approaches in the classrooms, as it is the case of constructivism/constructionism, project-based and problem-based learning (Gura, 2007). The unique features of ER have been used to promote multidisciplinarity and collaborative work and to foster student's motivation, imagination, creativity and logical thinking. As a result, this tool can be used to promote a positive technological development of the youngsters (Bers, 2008).

Although the aforementioned results are substantiated by a considerable amount of literature, the fact is that the available studies are mainly descriptive and of qualitative nature. Indeed, fundamental questions, such as "Is ER a suitable tool for basic school students?", "What are the contents/ skills that can be taught/ learned using ER?" or "What ER activities are more suitable for the different subjects and skills of the basic schools?" remain largely unanswered.

This paper proposes a methodology to conduct studies that provide an answer to those questions, combining several types of evaluation instruments of a qualitative and quantitative nature. We will also report on the on-going work to validate this proposal.

Our proposal is made of two distinct components: (*i*) the overall planning of a set of ER sessions to conduct with basic school students; (*ii*) a number of validation instruments to apply, in order to allow the quantitative and qualitative evaluation of ER as a pedagogical tool.

Regarding the first component, the overall planning encompasses three distinct stages:

    (1) a mandatory set of sessions that are used for the students to learning the main concepts of Robotics, using the Lego Mindstorms ER kits;

    (2) a number of modules that apply ER to specific subjects and skills of basic school curricula;

    (3) a number of possible multidisciplinary projects to conduct with the students.

Regarding the second, an example will be provided where ER is used for subjects related to the concepts of multiplication and division in Mathematics for the 4th grade. The latter will be exemplified considering the development of robotics-based storytelling projects.

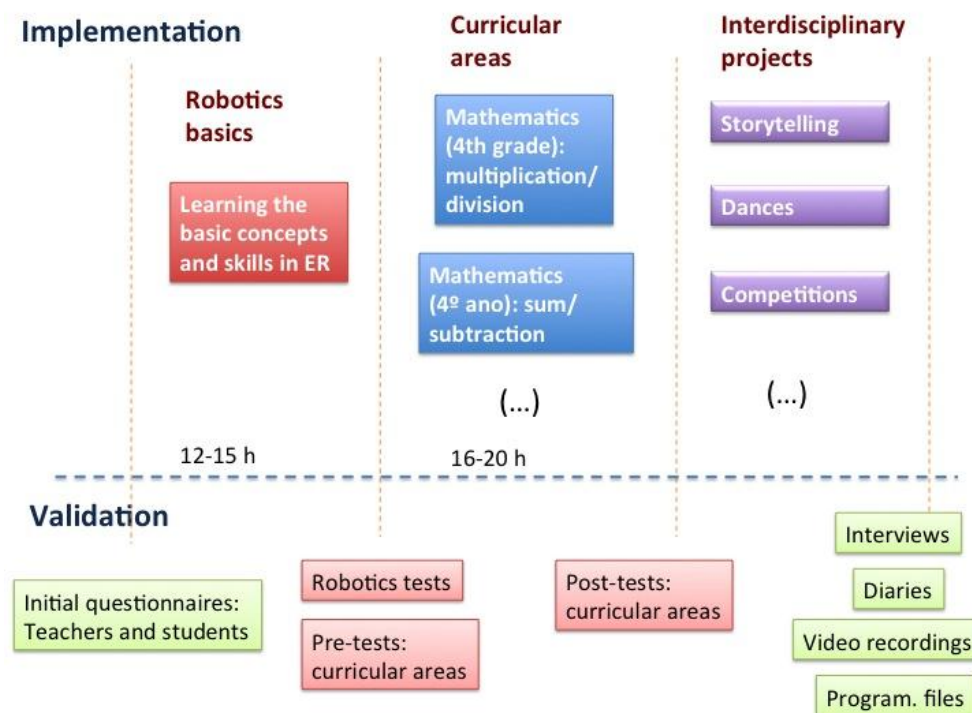
The previous plan will be accompanied by a set of instruments to be applied in different time points within the study, as detailed in Figure 1. These will include qualitative instruments, such as: initial questionnaires about student perceptions, diaries where students report the events of the sessions, descriptions/videos of the sessions, interviews with students about the sessions and students programming files (used to understand problem solving strategies). Also, quantitative instruments will be applied to evaluate the improvement of the students in particular skills/subjects. These will mainly consist in pre-tests and post-tests about relevant subjects.


Figure 1: Overall schematic representation of the proposed methodology

The remaining of this paper is organized as follows: in the next section the main characteristics of ER are reviewed, together with its pedagogical potential; next, the sessions that are proposed in this work are thoroughly described; the following section describes the validation instruments that were developed on this work; finally, conclusions are drawn and future work is outlined.

EDUCATIONAL ROBOTICS: CHARACTERISTICS AND POTENTIAL
In this section, the basic characteristics of ER will be reviewed and analyzed, focusing on the features that make it an attractive pedagogical tool. Next, the basic school contents and skills that can be addressed using ER will be reviewed, with an emphasis on Mathematics.

Features of Educational Robotics
A number of potentialities are normally attributed to ER in the teaching/ learning process. Some are briefly discussed here.

Motivation and enthusiasm: This is probably the most common feature mentioned by ER researchers. Indeed, the enthusiasm of all the participants (teachers, parents, students) in ER activities constantly mentioned in the descriptions of ER activities. In fact, ER seems to be able to motivate and involve students in learning by stimulating their natural curiosity. Given these reports, it is not surprising to find that ER is usually a good solution to motivate students in "difficult" subjects such as Mathematics and Sciences, where good results have been reported (Nagchaudhuri et al, 2005)]. Portsmore et al (2001) even report students that were always ready to work during breaks and other spare time. It is also reported by some researchers that

students that are normally inattentive in daily activities, show a special motivation in robotics activities (Rogers and Portsmore, 2004).

Multi-disciplinarity: Robotics is clearly a multidisciplinary field involving a set of disciplines like Physics, Mathematics, Computing or Electronics. The activities in ER integrate a number of subjects and skills, from areas such as Mathematics and Sciences, but also Arts and Languages. Thus ER possesses all the necessary conditions to allow multidisciplinary activities promoting a transversal learning of the different subjects (Ribeiro, 2006). Currently, the traditional learning systems do not seem to be prepared to provide challenges where the solutions require knowledge and skills from different fields, rather imposing scattered knowledge in distinct subjects (Morin, 1999). ER may provide a contribution to overcome this problem.

Project-based learning: Most ER activities, such as competitions or robotics clubs, revolve around the notion of a project that typically involves several stages (e.g. design, construction, programming, testing) that require distinct skills and knowledge. The notion of being involved in a project with a tangible outcome implies a different kind of commitment from the students in the required tasks and reinforces the connections with the real world and the meaningfulness of the learning process. Also, the students are called to make decisions that have an impact on the outcome of the project, thus making them in more active subjects in the learning process.

Collaborative work: Most of the activities involved in robotics are executed in teams working in tight collaboration. The decisions made while developing the projects are, therefore, reached through a process of group discussion. The efficiency in communicating good ideas and persuading the colleagues to adopt them, as well as the capability of accepting good suggestions are major ingredients for the success of the projects. Thus, ER activities are excellent means of promoting collaborative work and communication skills (Castilho, 2002).

Problem solving. When involved in ER activities the students (and of course also the teachers) are faced with numerous problems that originate from the obstacles that have to be overcome to reach the goals implied by the aim of the project under development. The fact that these problems arise from the real world makes them very different from the "artificial" problems solved in the classrooms. Indeed, these real world problems can be difficult or impossible to solve, require the application of other techniques to be solved (e.g. trial and error procedures) and sometimes the solutions are a best effort and not a "perfect" solution.

Imagination and creativity: The idea of "novelty" is normally connected with imagination, and those are related to the processes of problem solving. The processes of building and programming robots require a process of creativity, inviting the students to innovate in the process of problem solving. With ER, students develop their creativity by designing and creating their prototypes, attending to the final aim of the exercise. By going from a set of blocks and building and programming their robots, children are challenging their creativity.

Logical and abstract reasoning: The process of building a robot implies the capacity of planning and designing it in order to be able to work well under a given environment and accomplish a number of tasks. This implies a process of modeling the robot and the environment in an abstract way, in order to predict its behavior. Furthermore, the observation of errors implies the ability to reason about alternative scenarios and address concepts such as robustness. On the other hand, the programming of robots is conducted using a symbolic visual language, where the student needs to be able to map a set of symbols into the robot's physical behavior and predict the behavior of a given program or sequence of instructions. By projecting himself into the robot, the student is thinking about the process of thinking (metacognition) (Lau et al, 1999).

Autonomy: The whole process of developing a robotics project, where students try to solve a given challenge, through planning, building, programming and testing robots provides numerous problems that require an autonomous attitude from the student and the capability to use previous knowledge to search for the solutions, also resorting to heuristic approaches. Teachers have the role of making available learning environments where the student can feel safe in applying her/his ideas and searching for the appropriate knowledge. ER provides a suitable platform to achieve this endeavor (Castilho, 2002).

Educational Robotics and the basic school

Robotics has been used, over its path in Education, as a useful tool for the learning of distinct contents, as well as for the acquisition of numerous skills. Within this large set, the areas of Physics, Mathematics and Informatics are normally emphasized, being the ones more directly connected with Robotics. Robotics provides an excellent mean to make lots of different mathematical concepts, at all levels, into very tangible and useful concepts. Robotics makes possible to design activities that implement project based learning approaches.

Furthermore, Robotics also allows working concepts related to areas like Arts Education. In fact, when planning and building robots a number of skills related to these subjects come into play. On the other hand, some of the Robotics activities (e.g. competitions) have been developed in order to include Music and Dance as major areas, being approached activities that involve different types of choreographies.

Robotics can be used in the teaching/ learning of some of the contents and skills related to the major areas of basic or elementary school (i.e. within the first 4-5 years with students between 6 and 10 years old). Indeed, many of the major contents from areas like Mathematics, Sciences, Languages and Arts can be included into well designed and planned Robotics activities. An analysis to the curricula in the Portuguese system (CNEB, 2001) allowed to identify, for the main curricular areas, a set of application domains, learning experiences and contributions to reach the proposed basic skills, detailed next.

Mathematics. The emphasis on Mathematics in this level should be focused in solving problems, thinking about them and communicating with others to exchange ideas. Robotics offers a field full of opportunities, allowing to work on the main skills of the different domains, such as Arithmetic, Geometry, Algebra and general problem solving.

Sciences. Robotics can contribute for reaching the main aims in the teaching of natural and physical sciences, such as: acquiring a general understanding of the ideas and structures that explain scientific concepts; understanding and applying the procedures of the scientific research; questioning the impact of Science and Technology in our societies. Robotics is able to provide a set of learning experiments that include planning projects with certain aims, detailing the major steps, since the definition of a problem to the understanding and divulgation of the results and doing cooperative work.

Technological Education. Technological Education should be built upon the development and acquisition of skills in a sequence of learning steps along the elementary school levels. These should be able to integrate concepts and skills shared with other areas and promote the application of these concepts into new situations.

Focusing on Mathematics, ER offers a broad set of opportunities allow to plan, build and program robots using and improving skills previously acquired by the students in several subfields of Mathematics, but also leading to the discovery of new skills not yet acquired. ER projects illustrate clearly the relationship between Mathematics and its practical applications, providing numerous examples. Robotics involves essential mathematical skills such as measuring, counting, calculating mentally and estimating. These are included in the basic fields of arithmetic, estimation, algebra and geometry. Furthermore, these are not presented in isolation, but fully integrated in a way no text book can provide (Gura, 2007).

Within the Mathematics curriculum of elementary schools, ER can offer its contribution in the following subjects:

- *Numbers and calculations*: execute mental calculations, estimate approximate values and decide upon its reasonability; interpret numeric problems and connect to real world; identify arithmetical operations to execute in a given problem and explain the methods used;
- *Geometry:* plan and execute geometrical constructions, analyzing their properties, using software and raw materials; visualize and reason spatially in problem solving; understand to concept of perimeter, area, volume; measure and estimate spatial measurements; argue using visualization and spatial thinking;
- *Algebra and functions:* analyze numerical relationships representing them symbolically and explaining them in current language; build and interpret tables and graphics; understand and use the concepts of correspondence and transformation.

SESSIONS FOR EDUCATIONAL ROBOTICS IN BASIC SCHOOLS

This section will provide the description of the sessions that were planned as a result of this work. The overall set includes three distinct groups:

- sessions that are used for learning the main concepts of ER;
- sessions applying ER to specific subjects of basic school curricula, in this case applied to subjects related to the concepts of multiplication and division in Mathematics for the 4th grade;
- a number of possible multidisciplinary projects to conduct with the students exemplified considering the development of robotics-based storytelling projects. The three components are further described in the next sub-sections.

Also, all the materials mentioned in these sections are provided in a web site named RoboWiki (http://darwin.di.uminho.pt/robotica) written in Portuguese. This site also includes other materials to help students and teachers to get involved in Robotics, aiming to be a portal, where ER resources can be shared within the community.

Learning the basics of ER

The authors have developed a course to address the basic concepts and skills involved in building and programming robots, using the Lego Mindstorms robotics kits. This course includes a set of planned sessions, with available scripts and other materials (presentations, videos, exercises, etc) that allow every teacher that has access to a few ER kits to implement the course in its own class. The full set of materials is available in the RoboWiki site.

The proposed sessions are organized in the following stages:

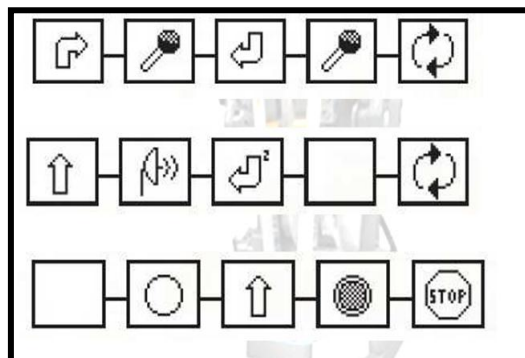
- Robotics basic concepts: what is a robot; history of Robotics; related videos; discussion on what makes a robot.
- Building robots using Lego Mindstorms kits: main hardware components; available Lego blocks; building exercises.
- Programming in the robot: using the interfaces of the robots to create simple programs; exercises (see example in Figure 2).


Figure 2: Example of an exercise to program on the robot (students have to identify the behavior of the programs shown)

- Programming using the NXT software: using the visual programming software to create programs and transferring those to the robots; several sessions with exercises are made available, together with their resolution (see example in Figure 3).

Exercise 6
a. Program the robot to move forward (power of the motors – 50) for 5 seconds
b. Program the robot to move backwards (power of the motors – 100) also for 5 seconds

Figure 3: Example of an exercise in the programming with the software section together with the solution

- Programming the robots to use sensors: more advanced programming blocks are explained that allow the use of the several types of sensors available (sound, ultrasound, touch, light). An example of an exercise is shown in Figure 4.

Exercise 15
a. Program the robot to move backwards.
b. Program the robot to react when the sound sensor is activated.
c. Program the robot to turn right.
d. Program the robot to stop when the touch sensor is pressed.
e. Program the robot to move forward 4 rotations.
f. Insert a *loop* surrounding the steps a to e

Figure 4: Example of an exercise in the programming with sensors section together with the solution

ER for Mathematical subjects

As an example of a curricular subject where Robotics can be used to enhance the teaching/ learning process, the authors chose *problem solving involving the arithmetical operations of multiplication and division*, focusing on students from the 4th grade. The proposed sessions are also provided in the RoboWiki site, corresponding to a set of activities and exercises with available solutions, with a predicted duration of 10 hours, that teachers can use in their classes. It is assumed that the students underwent the course described in the previous section, prior to the sessions presented here, i.e. they are aware of the basic concepts in building and programming the robots.

The main pedagogical objectives of these sessions is the following:

- To understand the meaning of the operations of multiplication and division and how they relate with each other;
- To calculate fluently and to provide reasonable estimates of the results of these operations;
- To discover, using ER, proportionality relationships among several measures: distance, rotations, time;
- To define procedures to convert the different measures among themselves, using multiplications/ divisions;
- To predict the behavior of robots using interpolation and extrapolation;
- To test hypotheses from experiments, using robots.

The proposed activities explore a set of proportionality relationships that the students need to understand in solving several types of problems in the programming of the robots. The strategy used consists in promoting the experimentation with the robots to motivate the inference of the relationships. Once the students understand the proportionality relationships they are able to use those in solving the exercises and predicting the behavior of the robots in certain situations. An illustrative example is given next in Figure 5. This type of exercises is also complemented with some games that are devised to work the same concepts but make the learning more playful.

Exercise 15:

Let us try to program a robot to draw a circle, rotating over itself.

a) Program your robot to rotate over itself using as a measure the number of rotations. Try the values of 1, 2, 3 rotations. What do you observe?

b) Measure the distance between the two wheels of the robot.

c) Using the measure from b calculate the length of the circumference that the robot will draw rotating over itself.

d) Measure the diameter of the wheels in your robot. Remember how you can use this value to know how to program the robot to travel a given distance.

e) How do you think you can program the robot to rotate over itself for exactly one turn.

f) What if you want the robot to complete three turns?
Figure 5: Example of an exercise in the sessions working Mathematics concepts

Multidisciplinary projects

The third group of ER activities in the proposed framework includes multidisciplinary projects. These are typically open activities that can be planned in the context of a given community. Some examples of these activities are shown below, being mentioned some projects from the authors' previous experiences:

- Dramatization of popular tales, using robots as the characters. Examples include stories such as the *Carochinha* (Ribeiro, 2006), *The Little Red Riding Hood* and *The Three Little Pigs.*
- Fashion parades, dance shows or other similar activities.
- Participation in Robotics festivals (e.g. RoboParty), often involving different types of competitions (e.g. dance, football, rescue);
- Other activities

From the authors previous experiences, these activities are quite effective in engaging both students and teachers to the field of robotics, promoting high levels of enthusiasm and motivation from all involved.

VALIDATION INSTRUMENTS

In this section, the instruments used for validation in each of the stages of the proposed methodology will be described. The explanation will be divided into qualitative instruments and quantitative instruments.

Qualitative instruments

According to Bogdan and Biklen (1994) the qualitative research has as its main features the natural background, where the researcher becomes the main agent involved in data collection. Therefore, the data collected are descriptive, typically words and pictures. Qualitative research focuses on the processes and less on the results or final products. Data analysis is performed in an inductive way. This type of research is not limited to analyzing behaviors but is mostly worried with the meaning that the subjects give to their actions and experiences, as well as with others. Merriam (1998) emphasizes that in qualitative research the subjects are not treated as numbers, but are analyzed in their natural environments. Using descriptive data allows us to better capture some behaviors, attitudes and opinions, enhancing richer and more significant conclusions. On the other side, they have a natural limitation in the lack of generalization.

The main qualitative instruments are listed next.

Direct observation and video recordings: The direct observation of the sessions is still one of the most valuable instruments in any study. This can be complemented by the use of video recordings that allow a more thorough analysis of some details that can escape the perception of the observer. Both the direct observations and video visioning can be written down in reports of each session that capture all the relevant actions, behaviors, reactions, attitudes and dialogues of the subjects. Some of the advantages of this type of study are the fact that the researcher can select, register and analyze only the most relevant occurrences and develops an informal and intimate relationship with the participants (Bailey, cited by Cohen and Manion, 1994). The direct observation is complemented by the use of specific sheets where some relevant information is collected (e.g. tasks completed by students).

Questionnaires (initial): An initial questionnaire about student perceptions relating to Robotics is recommended. The objective is to determine the previous ideas and attitudes of the students towards the field of Robotics. Also, including some other questions about the student's performance in different subjects and all relevant opinions and preferences prior to the study.

Diaries: The use of diaries where students report the events of the sessions is a common tool in Robotics studies. It allows an additional tool for the researcher, while it promotes the self-reflection of the students, an important feature in constructionist pedagogical tools.

Interviews (final): In the end of the study, oral interviews with the students allow the recollection of the main opinions about the study. The set of questions should be predefined but the researcher can change or add new questions to get deeper insights on some issues. The oral form allows the student to provide longer replies and the researcher to ask some follow up contextual questions.

Programming files: the programming files produced by the students while solving the problems can be kept, maintaining all versions of the programs for every student. In this way, the problem solving strategy of each student can be better understood and the evolution of the students can be studied in more detail.

Quantitative instruments
Also, quantitative instruments will be applied to evaluate the improvement of the students in particular skills/subjects and also to measure the skills of the students in some specific robotics tasks. The main quantitative instruments are listed next.

Robotics tests: These are used to measure the skills of the students in some specific Robotics tasks. A test is recommended after the stage of learning the basics of Robotics. The performance of the students in this test can be used to check if the students were able to learn the basic concepts in building and programming the robots. Some examples of these tests will be provided in the RoboWiki site.

Tests about curricular subjects: For every specific subject to be considered in the second stage of the proposed methodology, a pre-test and a post-test about the subject should be applied to the group undertaking the course. These tests should be carefully designed to assure that they are as similar in structure as possible. This should allow the comparison of the scores obtained in both tests as a way to measure the improvement in the performance of the students promoted by the ER. The effective comparison of these scores can be improved if two conditions are met: the number of students taking the course should be as high as possible to improve the statistical significance of the comparison; a control group that does not take the course should answer the pre and post-test in a similar way allowing the comparison of the results removing possible sources of bias.

CONCLUSION
In this work, a methodology for the evaluation of the merits of ER in basic schools was proposed. The authors believe this is am important contribution to an effective use of ER as a pedagogical tool confirming all the merits that many authors have identified.
This is still ongoing work and as such many important results, mainly in quantitative terms, are still missing. The future work will, therefore, be mainly devoted to the implementation of this methodology in the field, a task that is already under way.

Abstract: This paper discusses the vision of teachers and students have in using the Internet and how teachers use their work. It is based on the results of three qualitative surveys held in Rio de Janeiro, Brazil, hearing the views of two groups of teachers and a group of young teenagers on the subject. It uses as a background literature on digital media and social networks in articles published in two vehicles of deep penetration in Brazil, magazines *Época* and *Isto É*, between January 2009 and April 2010. Regarding the groups of teachers chosen, one consisted without any concern of filtration as the use of digital space in teaching, and the other group with teachers already include in their practices, the use of digital media. As for the youth group, were teenagers who finished high school and were on their way to university.

Keywords: digital media appropriation; teaching practices; pedagogical perspectives.

DEFINING THE SCENE OF DIGITAL MEDIAS[113]: CURRENT STATE OF TECHNOLOGY AND ITS TENDENCIES

This paper has as a start point the results of an unusual bibliographical data research, though it is very valid in the proposed context, starting with news magazines of weekly circulation in Brazil, Magazines Época[114] and IstoÉ[115], fully available through their websites (whole content is available for access and reading). As counterpoint to the positioning found in these magazines, we sought to understand in detail the unique universe of teachers and students, through pieces of research developed by the *Jovens em Rede* (JER) directory, a group of researchers of the Department of Education of the Catholic University of Rio de Janeiro (PUC-Rio), Brazil. These pieces of research aimed to find out when the digital medias enter the classroom, which attitudes come up with it and which factors are at play in its appropriation. Let us see these two axes in detail.

Concerning the bibliographic research, the period chosen for the article sampling was January 2009 to April 2010, because before 2009 there was a repetition of topics and comments about technology which in 2010 had been either overtaken by more recent versions or showed less lagged data. Evidently the content will be discussed here in general terms rather than in specifics of each technology mentioned. Despite the constant changes in technology we see in the era we live in, the generalizations exposed here are still valid in 2011.

We were concerned in bringing up the most common themes and trends that digital medias point to for the following years, besides showing the reader which scenery we are addressing when we research the use of technology by teachers. Our focus has been on accessible platforms via mobile computers and desktops, excluding digital TV and video-games console[116]. In a first screening, all articles that referred to information

---

[113] It is important to note that the expression "digital media" is used in this research as a synonym to ICT (Information and Communication Technology). We believe, however, "digital medias" a more appropriate term, since it unites all means of distribution and communication of digital content written, visual or audible.

[114] Available on: < http://revistaepoca.globo.com>.

[115] Available on: < http://www.istoe.com.br/>.

[116] Although they are part of the same group, they are still not part of the school routine, except for very specific experimental cases such as in the school that hosts the NAVE project, in Rio de Janeiro, and, besides that, they were not objects of study in our empirical researches (item 3 of this article).

technology and communication were selected. Articles involving education and technology were also given attention when the material was selected.

Among general themes of the past years, common in articles about technology, we have found the expansion of mobility of internet connection (represented by *cell phones* "all in one" and more recently *tablets*) and the ascension and control of social networks that are overtaking even sites such as *Google* in number of clicks, gathering services such as chat, forum, events, photo albums, scrapbook and contacts. The tablets tend to all be connected to wireless mobile internet, taking up similar functions to those performed by laptops and cell phones, though also adding applications that explore the potential of touch screen.

The social networks come as an extension of such trend, connecting people in real time through mobile devices, besides laptops and traditional desktops. We now tend to save our data on the internet, our e-mails, photos, videos and we can access them through any device that is connected to the internet, and this is known as "cloud computing", which means our data is not stored in our homes, but in computers that are not ours, enabling us to access it anywhere we go.

The blogs, one of the objects of our research (Martins, 2011), come into this context as data storage platforms, the previous generation to the current social networks (which also include in its architecture the structure of the blog through timelines). The focus of the blogs is not necessarily in the materialization of the author's social network. They are widely used because they meet the needs of a person or a group who produces contents, publishes it and has the control over the authorship, dimension and visibility of the posts (without size limit and more distinct than a *timeline*, with mixed posts, common in social networks).

As open platforms, many programmes for mobile platforms have arisen, allowing the users to write messages, update statuses, send photos and videos, all through phones and tablets. With the enlarging of internet band and 3G data transmission technology, the tendency is that the multimedia content predominates in transmission via mobile phone in the following years, allowing the production of audio and video and its posting almost in real time on online platforms such as social networks and blogs.

EDUCATION WITH MEDIAS IN ITS VARIOUS FACETS: THE CONSTANT DICHOTOMY *GOOD MEDIA* VERSUS *BAD MEDIA*.

Still analyzing the articles of the magazines, we realize the potential of social networks and blogs for education, through mobile communication in the classroom. Nowadays the students are able to access e-mails, write messages, take pictures and make videos through their mobile phones, laptops and tablets, as well as distribute the content in real time to classmates, creating therefore a community space through social networks and distribution platforms. The portable computer is not limited to the actual laptop but also the mobile phone (ever faster and with more memory available). Both devices can perform this function in the classroom, depending on the intended use.

Therefore the *portability* creates a digital ecology in the school, and a whole search field from the integration of the digital space into the school culture, which widens the classroom and the possibility of shared access to contents. If we used to talk about creating contents in the computer lab, nowadays the computers, the production and the distribution through digital networks are in the students' pockets.

Concerning the use that arises with these devices, two approaches, or tendencies, predominate from what the magazines published.

The first one concerns the fears of this new communicational (and social) configuration, found in the interviews published by the magazines (Mansur, 2010; Mansur, 2009). Among them there is the possible isolation of the teenager (Giron, 2009) and his excessive and even sickly dependence of technology (Moon, 2009), gained by many hours in front of a computer that is connected to the internet and in using mobile phones (Mansur & Lima, 2009; Cabral, 2009) in order to send messages and chat with friends, parents, relatives or even with strangers. Parents and teachers fear the lack of dialogue of this generation that is always connected and online. We understand that what is feared is the gap between this youth who connect among themselves, and teachers and parents who, for various reasons, some very plausible, did not develop this new competence.

Another fear concerns the quality and selectivity of contents by the young people – argument of the superficiality in approaching the content and reading it –, in facing an ocean of information without guarantee of reliability or security (Lima, 2009), as well as auto exposure in the broad network being espionage target, sexual abuse (Pereira, 2010) or cooptation for online crimes. Some other fears that were published referred to loss of acquired skills through earlier communication means, for instance the students' difficulty in handwriting, since many have been using computer and mobile phone keyboards to communicate (Rabelo, 2009).

As another type of approach, the arguments for technology and the new "multitasking human being" (Nogueira, 2009), capable of thinking and doing many tasks simultaneously is highlighted and complimented by optimistic researchers – in interviews found in the magazines –, who put their bets on another way of thinking, from the use of digital medias, in the extension of man's mental capability through the machine (extended cognition). Also common is the speech about integration with the machine (a radical fusion in the near future), represented by the picture of the *cyborg*, in which man and machine are indistinct, where the machine would not be just an extension of man and his abilities, but would become an indispensable part of life (Buscato, 2009), an omnipresent computing that is also invisible, with hidden devices in the various objects of daily use (Monte, 2009).

Through the articles published in printed media of general circulation and also, as we will see next, through the opinion of teachers and students taken from the three empirical pieces of research that are part of this paper, we see that there still is an approach of extremes concerning digital media, in which we find highlighted either positive or negative aspects, which we know exist and are part of its users' behavior, but either they become extremely generalized, or they are out of context, this way projecting in technology the responsibility for actions that are directed primarily by humans. We then find what Breton (2000) would denominate as a more utopian position or even worship of technology and another position as technophobic or hostile to technology.

THE *TRINOMIAL TEACHER-STUDENT-MEDIAS*: A *TENSION ZONE* THAT ARISES IN VARIOUS RESEARCHES AT JER

The debate outlined in this article comes from the clash of three pieces of research in which conventional tools, a focus group and a survey were used, and new ways to look at relationships inside the digital environment, the so called netnography[117].

The first, called *Youth in Network* (Mamede-Neves 2008), was accomplished between 2005 and 2008 and it happened from the analysis of a questionnaire on the use of medias, distributed and answered voluntarily by 998 students just out of secondary school, when they were enrolling for the first semester at PUC-Rio. Filtering the questionnaires, the survey heard 965 university students (61,85% of the total number of freshmen who had just arrived to PUC-Rio). The group was made of young people aged 17 to 19 y.o., divided into two groups: those who entered university through traditional Brazilian system or ENEM test (National High School Exam) and through PROUNI (University for All – governmental program). This survey allowed us a panoramic view of the use and the intensity of the digital media entering these youth's lives.

The second research was accomplished between 2008 and 2011, called *Masters on the Web* (Mamede-Neves, 2010). Part of its methodology was a questionnaire distributed to teachers from eight secondary schools, public and private, where the students of our first research had graduated, a total of 138 teachers. Its first aim was to investigate the relationship between the secondary school teacher and digital media and to compare it with their students' use of it. The teachers were selected at random, and answered the questionnaire were of different levels in use of digital medias. In the second stage of this research, we had four focus groups, in event organized inside PUC-Rio, with teachers who had answered the questionnaire and came voluntarily, in order to explain issues emerged from the analysis of the questionnaire.

The third research, called *Digital medias in and beyond the classroom*, conducted by one of the components of the research group and co-author of this article, Martins (2011), concerned the use of blogs by teachers called *pioneers*, in which one stage was the same questionnaire of the second research (this time an online version), during all year of 2010, coming to an intentional sample of 79 teachers who were part of discussion lists in which the theme of blogs was the focus and was part of their practice. The focus was in on teachers who are non-resistant to technological innovations, users of it in their day-to-day, and what they are doing differently when using digital media in the classroom.

Trying to make a synthesis of the results, the central issue that involves the *trinomial teacher-student-medias* was divided into the following argumentative levels, being the first the consequence of the second, as it follows (chain reaction):

1. The **student** uses digital media in his daily routine and has already made it natural as a tool, a fact that was proved by the research with youths out of secondary school, and he is considered by many as a *digital native* (Prensky, 2001), who supposedly has changed his habits when compared to the

---

[117] Netnography studies the manifestation of cultures in new supports, according to Kozinets (2002, p.2) "Netnography is a new qualitative research methodology that adapts ethnographic research techniques to the study of cultures communities emerging through computer-mediated communications."

pattern of students of previous generations. As to his practices, he can be considered also as an average user as to the diversity of use in his routine: communication (in social networks, chats, messengers, cell phone), games and entertainment applications. This student searches the web as an information source and questions the school as to its validity, as formative institution, and the teacher as owner of truth and authority, even though in contradiction to this he keeps an expectation that the teacher's "truth" and found in school books is always more reliable than those found on the internet.

2. The *teacher*, in general, acts on a concept of school that is based on fixed *contents transmission* and formal evaluation of the student, a pattern that starts with the exposition of content in linear order, going from mechanical out-of-context activity to evaluation through memorization. This pattern would collide with the student's daily experience with digital media, which is considered more open, flexible and operating by associations (links).

3. *Some teachers*, annoyed with their practices in the classroom and with the students' reaction and contestation, try to harmonize a culture based on a traditional evaluation system with tools developed on the web and out of the formal school context, based mainly on spontaneous exchanges through informal dialogues and collaboration to seek the solution of problems. They do it because they experience these interacting patterns more intensely in their digital lives. A less vertical, more collaborative-cooperative pattern is defended by these teachers, because it would be a more compatible approach to their students' experience out of the school, reaching out to a pattern of student's authorship that would be *less artificial*. Some teachers are fond of this new pattern and some have just begun to make changes in their pedagogical actions, but we see in these attitudes a *personal mission* aiming at reformation of pedagogical actions.

4. The *acceptance-resistance binomial*, which sums up the tension between *solidified pedagogical* actions and *emerging pedagogical actions*, reflects this dispute between so-called innovating practices and those pointed as lagged. We can see a *tension zone* in the school environment, in which the digital media, by its informal characteristics and open interaction, ends up being the catalyst.

We observe that there are two different fields of action and patterns of behavior, which causes a tension in the school environment: *out of the classroom* in an informal context, where the youth generally dominate and feel at ease (they are not monitored and evaluated), and *in the classroom* in a formal context, where the teacher, even the one considered to be "modern", has a formally established control.

The issue is on how to think the student's learning pattern, or how to think the teacher's teaching pattern, on topics that the school defines as priority and necessary in its curriculum (legitimate).., considering this teacher, called here *pioneer* (Midoro et al., 2003), a teacher who seeks to come up with alternatives that make the student *gain an interest*, using digital medias and its tools taken from an informal context for pedagogical means, though the student remains inside an institution that deals formally with contents.

The internet is a *factor of disturbance* the school ends up having to face, generating various problems, a collision between spaces that work with different logic, because the school is built with its rules and ways of operating that have been long ago established and shared by society (tradition). It's a matter of finding out what will be done, in terms of pedagogical practices, in an environment that has so many distinct possibilities, with the power of even changing the cultural and social behavior of the youth, the main constituent of this institution.

Evidently teachers do not react likewise in this context, some more resistant to the use of digital media (neophyte) and others accepting the dynamics of the media and making use of it (users or pioneers), as proved by the *Ulearn* research (Miodoro et al., 2003). In fact, the research *Masters on the Web*, when compared with the results of the research *Youth in Network*, pointed the unevenness of adhesion and diversity of uses between teachers and students.

We deal with the student and his representation of what learning and evaluation mean in a school, as well as with leaders, school managers and parents' representations. Each of these *public-agents* have their own view and personal experience with the internet, and with education, and this negotiation game reflects in the practice of the teacher, who has his own view on how the use of digital media should happen in formal learning processes.

We are also dealing here with disputes concerning behaviors in facing the teaching-learning process, a dispute involving *pioneers*, non-resistant, or more open to the introduction of digital medias in the classroom and the *traditionals* (or even backward) concerning the use of medias, preferring the use of resources and strategies established previously, in a *stability zone*, i.e., the student is less a producer and more a spectator of contents studied in the classroom. It is a collision of interests and personal definitions of "ideal teaching",

or a dispute of what should be more appropriate (a "paradigm") in the organization and development of learning inside the classroom.

TEACHING DISPUTES: THE *VANGUARD SPEECH* AND THE *TRADITIONAL SPEECH* AS THE TENSION SPOT IN TAKING IN AND USING DIGITAL MEDIA

It is common in speeches about the use of media in classroom the issue of *inevitability of adopting* the *emergent paradigm* that has come with the spread and use of digital supports. Obviously changing practices and approaches are part of the routine of relations in society and even of the dynamic of behaviors and rules among individuals, even though they are perceived very slowly in certain contexts.

Therefore we need to understand a little about how the reasoning about the inevitability of a change develops itself so that we might know which sort of dispute is at play, because among the teachers selected as *pioneers* in the Martins' research (2011), one of the main arguments brought up was that the way they operate is in harmony with the society and its current courses. The speech here that would be called *vanguard* would be characterized by the inevitability of adopting digital media in the classroom, because society would be marching towards change with the constant increase of this adoption (statistics that show increase in connection to the internet and digital support sales give support to this statement). In such context, the school would have to commit to change its teaching system, using collaboration and cooperation techniques between students and teachers (decentralization of teaching), and a more intuitive way of non-linear searching and organizing information, such as we find when observing the hypertextual architecture of the web.

From this point of view, the school that now cannot centralize the access to information and the distribution of knowledge through printed media (piles of books and magazines) given the instantaneous access on online data bases should modify its environment and its way of managing information for educational means, instructing the student on more open teaching methods.

The *modern* teacher (or pioneer) would then be the one who would not settle into an industrialized education, repetitive, unified and linear, i.e., he opposes to the *traditional* teaching, practiced by most teachers. Consequently, we realize that the digital media ends up carrying with it a speech about what it should change in terms of educational practices, in a way something that would come from the new digital environment that is nowadays increasing (its use) in its various forms (mp3 players, netbooks, tablets, mobile phones, ATM machines).

The one who opposes himself to this process would be a non-user traditional teacher and the teacher who shows a new way of behavior would be an active user of digital medias and of vanguard. Up to now the issue is quite clear, and we can see that in order for a pioneer teacher to exist there needs to have a traditional teacher or even one that is foreign to new technology, as contrasting positions.

We cannot uphold these radical categories, mutually excluding. Extreme limits are nonexistent in reality.

Another point that is not always clear is the constitution of agents and the way of influence in actions of this *new paradigm of education with media*. That's why we need to map out the *environmental conditions* in the process of adopting digital medias for educational means, aiming to clear up factors involved in a complex system of relations, such as the data collected in the third research with pioneer teachers and bloggers has shown.

ENVIRONMENTAL CONDITIONS IN APPROPRIATING DIGITAL MEDIAS BY THE TEACHER IN THE CLASSROOM

We are here nominating *environmental conditions* factors that are involved in teachers adopting digital, especially the internet, in *pedagogical action* with students, beyond a dispute between avant-garde teachers and traditional teachers in their use of tools and digital spaces. Among factors exposed through speeches gathered at the qualitative phase of Martins's (2011) research, that would be part of this environmental condition, we mention:

Factors out of the school environment:

For public schools, the *Brazilian government actions* accomplished throughout the country, in states and cities are necessary, not only to equip schools with essential digital technology but also to train the teachers permanently in what concerns inserting and incentivizing the adoption of digital media in classroom, their projects, and definition of maintenance of such projects when facing change of government and departments.

In a more general plan, the *guidelines of private companies*, that nowadays keep the main tools for free internet use, in the same way they make platforms available, such as Web 2.0 highly used by teachers, they can delete websites, because of insufficient numbers of clicks (and lack of advertisements), block them

changing them into paid websites, delete or add functions, without being concerned with educational projects that might be happening in their platforms.

Factors in the school environment:

The *school managers* and their guidelines for action (school policy) have an important role, by how they guide the school's general goals or how they guide the approach given to using digital media in some specific subject.

The *colleagues* more or less interested in the use of digital media have a relevant position on many levels, with encouraging words, destructive criticism, or even for being neutral in their resistance (indifference). This is one of the tension zones most mentioned by the teachers.

The *infrastructure available* in the school, quantity of equipments by students and how updated and conserved they are, the internet speed and available space (free or connected to schedules) is closely connected to external factors represented by governmental policies, concerning public schools. It can be represented by the computer lab or by private equipment owned by students (laptop and mobile phone).

The *parents' intervention* can be supportive and encouraging, but they are also critical of the activities, either because they fear digital media or because they lack knowledge on it. Could we then categorize them as *avant-garde parents* or *traditional parents*?

At last we have the *students' adhesion and support*, their engagement or distance in relation to the proposed activity, because, as the main constituent for which a school project is built, they become the thermometer of pedagogical actions. However, they are often considered as the last bit of a very complex interaction process, as this list shows. Considering what was discussed on the results of the Youth in Network research in what concerns their expectations, could we also categorize them as *avant-garde students* and *traditional students*?

As the empiric research of Martins (2011) has shown us, environmental conditions influence the adoption, maintenance or dropping of activities with digital media, because it was made clear that the teacher by himself, even if he acts as a *technological and pedagogical pioneer*, is not able to create and maintain a permanent activity with the use of media, and many get frustrated when they have to abandon projects that, from their point of view, worked fine and had a significant adhesion from their students.

Though the internet allows a personal website or a project to be opened very easily, if the teacher gets hindered by the instability of such environmental conditions, in his pedagogical action, it becomes difficult to follow through with activities. It is not unusual that we find abandoned blogs, with old posts or that report one year or one semester of activities with a group of students.

WARNING: GUILTY WANTED...

Because we have so many *surrounding conditions*, it is common, in teachers' speeches, a vagueness as to who is the "guilty one" of a failure with a project involving digital medias, sometimes being the school and its management, other times the teachers and their lack of adhesion, sometimes the parents, or lack of equipments or their inexistence, and at last the students' lack of interest. A mix of these factors is common in their speech.

More broadly, we can say that these factors, in a complex interaction system, make the pedagogical activity with digital media very unstable during a period of time, and in a school year. For instance, the speed with which internet tools come and change is one factor that can stop an ongoing project in the school, when a tool that was free for access gets converted into paid tool or it's deactivated. That happened to *Ning* for social networks and to *Google Wave* for communication and group work, both mentioned by *pioneer teachers* in our work groups.

We can add here, generally speaking, a factor that is connected to digital media itself: its constant modification in terms of technological architecture, as mentioned in items 1 and 2 of this article, argument built from the data research from weekly magazines. Digital media is built based upon a complex network involving private companies, public corporations, political ideology, market battle, agreements for adoption of standards, serious disputes between products.

All of this creates an unstable system that has results such as shown by the research of Martins (2011), which has concluded that pioneer teachers, in case they cannot catch their breath (time and resources) to follow these modifications, might stop their work and their expectations frustrated. In other words, the resource known and used today might become inexistent or overtaken by new standards tomorrow. This fact made the process of defining oneself filled with anxiety, when the author of the research promoted a self-categorization list of the discussion, where many teachers did not know whether they would define themselves as pioneers, modern or neophytes, changing their category time and time again or choosing many categories.

CONCLUSION: AN EVERLASTING TRANSITIONAL PHASE?

We start this conclusion opening a reflection about two words: *instability* and *transition*.

Let us think about the instability of technological changes. When we consider categories such as *pioneers*, *practitioner* and *neophyte*, or even *digital native* and *digital immigrant*, we need to know what type of technological object and use they relate to.

This issue of temporal location of the exact way we use media can cause some confusion about categories such as *avant-garde* and *traditional* for a type of behavior, and consequently what is considered to be a new or an old paradigm.

Can we then talk of an *everlasting transitional phase*? It seems that the dynamics of digital media development, a long process of media evolution dated from some millenniums (from the first language constructions to the digital highways), is nowadays a dynamic of constant and accelerated changes. Successive transitions, in constant acceleration, in an unstable universe, seem to be the law when we think of media in the past decades.

If we are talking about teachers and their behavior when facing such transformations and transitions, we can also suppose that a student might be in similar categories, in what concerns his learning process. It might sound strange that we have a category for a "traditional" student who has lived with older patterns and has inherited them directly, but this is not only possible but it exists and is more common than we think.

Our youth today are born into a culture of linear reading, where the book is sacred and the assessment summative and meritocratic. Since early age, they are subject to this, and at this point they reflect the ties of the cultural rules. We have seen in some of the teachers' speech in the research of Martins (2011) that there are students resistant to more open and cooperative learning patterns. Therefore, we can find the habit secularly brought into the school concerning content explanation and assessing processes in school teaching, as well as the "choice" the students make connected with how much time they wish to spend doing something they do not regard as very important (acquiring knowledge to do a test and get a passing grade).

For the teacher who aspires to use digital media in the classroom, besides the resistant teacher we now find the *resistant student*. This seems hard to grasp, but it is reality.

Therefore, the question mentioned makes us think about diversity of teaching methods and strategies, making it seem, mistakenly, that the choice for a specific model as the only standard of teaching-learning is desirable. Absolutely not.

We here defend a more diversified way of teaching, less *manufactured* in the sense of it being the only option for everyone. We also drift away from the dual issue *new pattern – old pattern* and get to the question: what patterns can I adopt considering my students and the surrounding conditions where I find myself (managers, parents, co-workers and governmental politics)?

This way the teacher does not stop carrying out forefront actions, at the same time, he is aware of factors which he cannot control completely, such as school policies and governmental policies, cultural and methodological traditions of the institution he is in.

What is proposed here, therefore, is that the binomial teacher-learner might be analyzed not only through their media use, but, mainly, that they should be located in ecology of factors which forms the *stable/unstable school structure*.

Such analysis is complex in itself, but, we believe, it would help first and foremost to take away the huge expectation and responsibility placed on the teacher, who starts to place himself in a broader context and be aware of the most adequate strategy for the moment, being even able to adapt it over time. Through research developed by JER the unevenness in adopting technology is evident among teachers and students. However, if we compare our results with research about adoption of digital media done five years ago (Abreu & Nicolaci-da-Costa, 2006; Silva & Azevedo, 2005), we can see that teachers are much more familiar now with computing and internet technology in their day-by-day routines, naturalizing them as they use them, whether by study/work obligation or by volunteer adoption.

If we think more broadly about the fact that technology changes its format and new "natives" come up all the time, homologue to balancing of the course of human life, an everlasting technology transitional phase will always generate a development curve outlined by avant-garde and retrogressive, but always showing a greater number of people who are constantly moving, because there will never be an evenness in levels. It becomes more important, then, to create conditions for mapping the surrounding so that this teacher might be able to determine which way to go, when to start and with whom, without pointing anyone as being "guilty".

237 - High School Students' Satisfaction with Studying Mathematics by Themselves Using Learning Object Material

Sakorn Boondao

Sukhothai Thammathirat Open University,
Pakkret, Nonthaburi, Thailand.10210
sakorn.boo@stou.ac.th, sboondao@gmail.com

Abstract: Information and Communication Technologies (ICT) usage has dramatically increased in society and in people's lives; particularly among younger people. Therefore, it was interesting to give students an opportunity to study mathematics via Learning Object Material (LOM) in CD ROM. The lessons were produced to help students studying by themselves. The objectives of the study were to investigate students' satisfaction with the study method and to measure their achievements.

The population was high school students. The sample consisted of 200 students; 50 randomly selected from each of four schools. The instruments were six LOMs in a CD ROM on the topics of the circle and the parabola, and a set of questionnaires. Each LOM was produced using Flash MX and included a pretest, contents and examples, a variety of exercises with solutions, pictures and graphs, and a posttest. The questionnaire asked about students' satisfaction with studying from the LOM and the presentation of the contents.

Students were asked to study the contents from the LOM before studying in class with a teacher. They were told to follow the instructions and keep the results of the pretests and posttests. After studying, they were asked to fill in the questionnaire. Five students from each school were interviewed about studying from the LOM. Completed questionnaires and pretest and posttest results were presented by189 students (94.5%).

It was found that students were generally satisfied with the lessons. They enjoyed studying from LOM. They were able to repeat the lesson when they did not understand. They liked to study the lessons because they were able to study any time they wanted to. They had reviewed basic knowledge that prepared them for the lesson. They gained more knowledge. They were able to evaluate their knowledge. The lessons contained enough content and exercises and were appropriate. Students said they preferred to study the lessons from LOM after studying in the class because they would like to have some basic background about vocabulary first, even though this was provided in the LOM, and review the lesson before examination. Results, compared by t-test, showed that the scores on the posttests were significantly higher than the pretests at a .05 level.

The results showed that students were able to study by themselves from media with contents carefully designed to meet their needs. Students also benefitted from the flexibility of usage. Students gained knowledge, studying by themselves, before studying the same contents in the class with their teacher. They preferred, however, to study the lessons from LOM after the class. They may be used to being taught in the class. Studying independently from media is not the learning culture of Thai students at school level. If schools introduce media as a supplement it will build students' confidence to find knowledge outside the class. It will not only help students to gain knowledge, but also help teachers to spend less time teaching and help the schools in case of teacher shortages. It is concluded that technology can change the culture of education.

Keywords: Learning Object Material, LOM, Students' satisfaction, Study mathematics via LOM

INTRODUCTION

This is the era of technology. Technology has influenced a lot of development and changed human society. Most people have more access to media. Society must adapt to this new era to survive. In the education system it is the same. Technology is being used as a tool for teaching and learning. It can make learning really interesting for today's students for whom books may not be exciting as educational content from computer that is designed to interact with their lessons quickly, immediately and easy to use anywhere at any time without prior notice and there is no need to carry. As Maharey, Steve (2011, 2) noted "New technologies and new models of learning may finally change the way we have learned for centuries." He also said that "the best of collaborative face-to-face learning and a rich digital environment that will also support collaborative learning."

Information and Communication Technology (ICT) usage has dramatically increased in society and in people's lives; particularly among younger people. Therefore, it was interesting to give students an opportunity to study mathematics via Learning Object Material (LOM). A Learning Object is a unit of instructionally sound content centered on a learning objective or outcome intended to teach a focused concept. It is a fundamental building block composed of all the instructionally necessary components to comprise a self-contained instructional unit. While traditionally, education content came in blocks lasting for several hours, learning objects are a much smaller unit of learning, typically ranging from 2 to 15 minutes. Each learning object can be taken independently and is reusable. A single learning object may be used in multiple contexts for multiple purposes. They can be grouped into larger collections of content, including traditional course structures and have descriptive information allowing them to be easily found by a search (Beck, Robert J., 2009). Learning Objects can be delivered over the internet and can be accessed by a number of individuals simultaneously, with minimal effort, reducing the need for instructors to develop their own instructional components. They allow for increased speed and efficiency of instructional development and decrease faculty preparation time (Freeman, 2004).

Teaching and learning by using LOM can be an alternative option that allows students to learn by themselves. LOMs might not be able to replace teachers, but they can help students to cope with certain problems. Students can interact with the lessons and be able to study them as many times as they wish. If students gain knowledge and satisfaction from the lessons they will pay more attention. It helps teachers. The teacher can arrange more lessons on digital media and take them into the classroom as part of instruction where appropriate. This project was initiated by Sukhothai Thammathirat Open University to provide media for its students who study on their own, and for social service. Since the contents of mathematics overlapped with high school curriculum, it was interesting to see whether learning by distance be suitable for high school students or not. Objectives of the study were to investigate students' satisfaction with the study method and to measure their achievements.

METHOD OF STUDY

The population was high school students. The sample consisted of 200 students; 50 randomly selected from each of four schools. The instruments were six LOMs in a CD ROM on the topics of the circle - concept of circle, equation of a circle, the center point and radius of a circle in a general form of the equation, and parabolas with vertices at the origin and at any point on the X or Y axes, and their applications, and a set of questionnaires. Each LOM was produced using Flash MX and included a pretest, contents and examples, a variety of exercises with solutions, pictures and graphs, and a posttest. Voice recordings providing an introduction to the LOM, outlining the objectives and explaining how to do some of the examples was included. Basic knowledge was supplied in cases where needed. These LOMs were approved by an expert committee appointed by The Computer Department of Sukhothai Thammthirat Open University. A set of questionnaires asked about students' satisfaction with studying from the LOM, how they study from LOMs and the presentation of the contents. The five-point Likert Scale, strongly agree (SA), agree (A), no opinion (NO), disagree (D), strongly disagree (SD) was used. There were 24 items and an open ended request for suggestions. It was examined for validity by three specialists and tried out with 48 students of year 10 who were not in the sample. The Reliability of the questionnaire was .866 by using Cronbach's Alpha.

Students were given a CD ROM of LOMs. They were required to study the contents before studying in the class from their teachers. Questionnaires were completed after the study. There were 189 out of 200 students (94.5%) who returned completed pretests, posttests and questionnaires. The data from the questionnaires were analyzed by using percentage, average and standard deviation. The comparison of the pretests and posttests was made using the t-test. The average scores from the rating scale of questionnaire were interpreted as follows.

$\overline{X}$	Level of satisfaction	Level of Opinion
4.50 - 5. 00	Very satisfaction	Strongly agreed
3.50 - 4.49	Satisfaction	Agreed
2.50 - 3.49	Moderate	Moderate
1.50 - 2.49	Dissatisfaction	Disagreed
1.00 - 1.49	Very dissatisfaction	Strongly disagreed

RESULTS

The results were divided into four topics: 1) students' background, 2) students' satisfaction towards LOM, 3) how students studied from LOM and 4) students' achievements.

Students' background: There were 189 students from four schools. Nearly three quarters (72.5%) were females. More than a half (69.8%) studied in the Science and Mathematics stream. About a third of them (36.5%) received grade mathematics grade point average from last semester of 3, followed by grade 2 (30.7%) and grade 4 (25.4%). The rest received grade 0 (1.6%). Details are in table 1.

Table 1: Students' background

Item	N	%
Sex	**189**	**100.0**
Male	52	27.5
Female	137	72.5
Study Stream	**189**	**100.0**
Science and Mathematics	132	69.8
Mathematics and Language	57	30.2
Mathematics grade point average from last semester	**189**	**100.0**
4	48	25.4
3	69	36.5
2	58	30.7
1	11	5.8
0	3	1.6

Satisfaction towards LOM: The satisfaction was divided under two headings, students' satisfaction with the lessons and the design as follows.

Students' satisfaction with the lessons: In general students were satisfied with the lessons (3.76). The data were shown both by average and percentage. The items were ranked from the highest average to the lowest. Students were satisfied that they were able to repeat the lesson when they did not understand (4.49). They studied the lessons in order as required (4.17). They liked to study like this because they were able to study any time when they wanted to (4.13). They found that they were able to review the basic knowledge that was included in the lesson (4.12). Most importantly, they said that they gained more knowledge (4.11) and were able to evaluate their knowledge (4.04). Details are in table 3.

Table 3: Students' satisfaction with the lessons

	N	SA	A	NO	D	SD	$\overline{X}$	S.D
Students' satisfaction with the lessons.							**3.76**	**.394**
I was able to repeat the lesson when I did not understand.	189 (100.0)	97 (51.3)	87 (46.0)	5 (2.6)	0 (0.0)	0 (0.0)	4.49	.552
I like it because I was able to study any time when I want to.	189 (100.0)	75 (39.7)	77 (40.7)	27 (14.3)	7 (3.7)	3 (1.6)	4.13	.904
I had reviewed basic knowledge that added in the lesson.	189 (100.0)	45 (23.8)	123 (65.1)	19 (10.1)	2 (1.1)	0 (0.0)	4.12	.608
I gained more knowledge.	189 (100.0)	53 (28.0)	107 (56.6)	27 (14.3)	1 (0.5)	1 (0.5)	4.11	.694
I was able to evaluate my knowledge.	189 (100.0)	45 (23.8)	109 (57.7)	33 (17.5)	1 (0.5)	1 (0.5)	4.04	.695
I was satisfied with lesson in general	189 (100.0)	23 (12.2)	102 (54.0)	51 (27.0)	9 (4.8)	4 (2.1)	3.69	.826
I enjoyed studying with the LOM.	188 (100.0)	18 (9.6)	112 (59.6)	40 (21.3)	15 (8.0)	3 (1.6)	3.68	.818
I did not feel embarrassed when I made a mistake as in the class.	188 (100.0)	52 (27.7)	63 (33.5)	39 (20.7)	26 (13.8)	8 (4.3)	3.66	1.147
I like it because I was able to control my studying.	189 (100.0)	33 (17.5)	67 (35.4)	70 (37.0)	16 (8.5)	3 (1.6)	3.59	.928
I felt that it was not fun like studying in a class.	189 (100.0)	29 (15.3)	50 (26.5)	81 (42.9)	26 (13.8)	3 (1.6)	3.40	.960
It was convenient because there was no need to attend the class.	189 (100.0)	24 (12.7)	71 (37.6)	55 (29.1)	29 (15.3)	10 (5.3)	3.37	1.057
I am able to learn and to understand mathematics by myself.	189 (100.0)	10 (5.3)	75 (39.7)	75 (39.7)	27 (14.3)	2 (1.1)	3.34	.826
It was more difficult than studying in the class.	189 (100.0)	25 (13.2)	46 (24.3)	78 (41.3)	36 (19.0)	4 (2.1)	3.28	.988

Students' satisfaction with the design: In general students were satisfied with the design (3.76). They were satisfied with the variety of exercises which helped them learn more (3.90), the pretests and posttests were appropriate (3.89), animation/pictures/graphs made the lessons interesting (3.89), the given solutions helped to understand the contents more (3.85) and there were enough examples to learn (3.81). Details are in table 4.

Table 4: Students' satisfaction with the designing

Item	N	SA	A	NO	D	SD	$\bar{X}$	S.D
Students' satisfaction with the designing.							**3.76**	**.566**

The pretests and posttests were appropriate.	188	33	110	38	6	1	3.89	.738
	(100.0)	(17.6)	(58.5)	(20.2)	(3.2)	(0.5)		
The animation/pictures/graphs made the lessons interesting.	188	43	95	39	9	2	3.89	.846
	(100.0)	(22.9)	(50.5)	(20.7)	(4.8)	(1.1)		
The given solutions helped to understand the contents more.	188	31	109	38	9	1	3.85	.766
	(100.0)	(16.5)	(58.0)	(20.2)	(4.8)	(0.5)		
There were enough examples to learn.	189	35	95	47	12	0	3.81	.809
	(100.0)	(18.5)	(50.3)	(24.9)	(6.3)	(0.0)		
There were enough exercises to drill and to learn.	189	32	91	47	15	4	3.70	.916
	(100.0)	(16.9)	(48.1)	(24.9)	(7.9)	(2.1)		
The recorded voice explanations help to avoid the contents being boring	188	24	58	64	27	15	3.26	1.105
	(100.0)	(12.8)	(30.9)	(34.0)	(14.4)	(8.0)		

How students studied from LOM: Students were asked how they studied from the LOM. They had discipline in that they studied the lessons in order as required (4.17). They thought about and solved the problems every time before they answered (3.89) and studied the lessons seriously (3.76). Details were in table 5.

Table 5: How students studied from LOM?

How students studied from LOM?	N	SA	A	NO	D	SD	$\bar{X}$	S.D
I studied the lessons in order as required.	186	63	94	27	2	0	4.17	.707
	(100.0)	(33.9)	(50.5)	(14.5)	(1.1)	(0.0)		
I thought about and solved the problems every time before I answered.	189	37	103	41	7	1	3.89	.774
	(100.0)	(19.6)	(54.5)	(21.7)	(3.7)	(0.5)		
I studied the lesson seriously.	189	25	100	58	5	1	3.76	.732
	(100.0)	(13.2)	(52.9)	(30.7)	(2.6)	(0.5)		
I answered the questions by trial and error and clicked the solution.	188	21	65	34	45	23	3.09	1.234
	(100.0)	(11.2)	(34.6)	(18.1)	(23.9)	(12.2)		

Students were asked whether they had problems using the LOM or not. Nearly three quarters did not have any problems while 26.6% of them did have problems. Details are in table 6.

Table 6: Problem in using LOM

Item	N	%
Problem in using LOM	**184**	**100.0**
No	135	73.4
Yes	49	26.6

When interviewed about problems using the LOMs, students said when they did not understand they could not ask anybody; some contents were hard to understand; they would like to have more examples and the sound was slower than they could read and more formal.

Also in the interviews, students said they preferred to study the contents in the class first and then use LOMs as supporting media to review the contents before the examination; but it was alright to study the LOM before the class because they could understand the contents quicker than without it. Some students said their parents were curious about what their children were watching on the computer when they heard the unfamiliar voice explaining. Their parents were pleased to find out that their children were studying from a LOM instead of playing games.

Students' achievements

Students' achievements were compared from the average scores of pretest and posttest, 9.94 and 16.99 respectively from the total of 25. It was found that the posttest scores were significantly higher than the pretest at a .05 level. Details are in table 6.

Table 6: Comparison students' scores on the total pretests and posttests

Item	N	$\overline{X}$	S.D	t	df	p
posttest	189	16.99	4.099			
pretest	189	9.94	4.087	56.988	188	.000

Since the average score on the posttest was approximately 65% of the total score (25 marks), it was interesting to investigate, using a t-test, whether students' achievement from the posttests scores were significantly higher than 65% of the total score or not. The finding showed that the average score of the posttests was significantly higher than 65% at a .05 level. Details are in table 7.

Table 7: Comparison the average score of the posttests with 65%

Item	t	df	p
posttest	2.480	188	.014

CONCLUSION AND DISCUSSION

It was concluded that high school students were satisfied with using LOMs. Their achievements showed significant progress. Students were satisfied with studying using LOMs because the LOMs were designed in small units with emphasis on concept, drill, enough exercises, immediate feedback and animations (Beck, Robert, 2009). Students were able to assess their progression. They were able to study as many times as they wanted, to gain knowledge. They did not feel embarrassed when they made mistakes as they did in class. They also found the instructions easy to follow and were not tempted to skip steps and just look at the answers.

These results were reflected in the outcome of the achievement. Students gained more knowledge and the average score was significantly higher than 65%. In general, Thai students' scores in mathematics are very low (Aramnet, Chuleeporn, 2010 and Intathep, Lamphaic, 2011). Aramnet, Chuleeporn said that the Deputy Education Minister Chaiwuti Bannawat reported that the average scores for the ONET (Ordinary National Educational Test) for year 6, year 9 and year 12 levels in Thailand were below 50%. Intathep, Lamphai (2011, 4) stated that in the 2011 ONET tests for students in year 6 and year 9 in mathematics the average score was 14.99%. She also reported that educators said that there was an urgent need for overhaul of the way students were taught.

The use of LOMs could be one alternative strategy for teachers not only to help students to become more interested in mathematics and more independent in their approach to learning, but also to help them gain more knowledge.

SUGGESTIONS

The results from the study showed that high school students were satisfied with studying from LOMs and their achievements on the posttests were significantly higher than their scores on the pretests as well as higher than 65% of the total score. It was an indicator that digital media can help students learn by themselves. The culture of teaching and learning may be changing, from face-to-face to independent study with some help from the teachers. Therefore, education institutions should pay attention to the possibility of sharing educational materials. It is not only cost saving but it helps solve the problem of teacher shortages and encourages students be independent learners. The sharing of Learning Object Material between schools would also benefit teachers by exposing them to a range of different approaches to the teaching of their subject, helping them to broaden their approach to their own teaching.

285 - Educating Teachers in ICT: from Web 2.0 to Mobile Learning

Ana Amélia A. Carvalho

Department of Curriculum Studies and Educational Technology, Institute of Education, University of Minho
aac@ie.uminho.pt

Abstract: This paper focuses and reflects on ICT programs for teachers in pre-service and in service enrolled in Master Courses at the University of Minho. We briefly present its evolution starting from the nineties. We propose five topics, beginning with a contextual understanding of learning in the 21st century, evaluation of online resources, creating educational resources such as Treasure Hunt and WebQuest to take advantage of the information available online, publishing and interacting using Web 2.0, and mobile learning. A study aimed at Master students from Educational Technology was conducted and inquired as to their Web literacy as well as their reception to mobile learning in schools.

Keywords – ICT, Web 2.0, Mobile Learning, Teachers training

This paper focuses on ICT programs for teachers in service and in Master Courses at the University of Minho. One of our concerns is related to ICT skills and competencies to be acquired by teachers in order to motivate their students, the Net generation, as Don Tapscott calls them, or the "thumb" generation (Rheingold, 2002). They must be familiar with the use of Web resources and Web 2.0 tools. More recently, mobile learning is an emergent concept that results from e-learning technical evolution. The teachers must be familiar with and know how to create interactive activities for mobile devices as students have several mobile devices they can use to learn anywhere at any time.

The UNESCO's project "ICT Competency Standards for Teachers" declares that schools and classrooms "must have teachers who are equipped with technology resources and skills and who can effectively teach the necessary subject matter content while incorporating technology concepts and skills" (UNESCO, 2008, p. 1). The Portuguese government has shown concern in up to date school equipment, teachers and students laptops through several initiatives such as "e-school "(e-Escola), "e-little school" (e-escolinha) with the laptop Magellan, and "e-school 2.0". Teachers training in school centers or in Higher Education must prepare teachers to be active and skilled in integrating ICT in their teaching contexts. We believe, as Richardson (2006) also pointed out, that if we want to have teachers to teach Web 2.0 technologies effectively, they must learn to use them effectively.

ICT PROGRAMS FOR TEACHERS

We briefly describe the evolution of the ICT programs which intends to integrate technological evolution. It has also a duration constraint. Before Bologna, our undergraduate students had two semesters of Educational Technology, a full year course integrated in a five year teaching program. With Bologna, we only have Master students that are enrolled in one semester only.

In the nineties, we started with Web 1.0, evaluation of the information online and the construction of Websites using FrontPage. They learned how to publish a website in a public and free server. This was very useful for them as they were able to create a website to support the resources for their students and the activities they would like to carry out online.

Later on, we introduced WebQuest, created by Bernie Dodge and Tom March in 1995, and the Treasure Hunt, as two modes of guiding students through selected websites (Carvalho, 2003).

With the appearance of Web 2.0, we introduced blogs and social networks such as Hi5, Facebook and Linkedin (Carvalho, 2006). Afterwards, we gave importance to podcasts, starting with audio podcasts, enhanced podcasts, vodcasts, and screencasts (Carvalho, 2010, Carvalho & Aguiar, 2010, Carvalho et al., 2009). Now, we feel it is time to introduce mobile learning in ICT programs.

Mobile learning is a natural consequence of the emergence of a new global digital communication society which enables new forms of learning to occur in different contexts (Sharples et al., 2009). Moreover, we realized that students in schools do not bring their laptops to class because they are heavy (Moura & Carvalho, 2008; Certal & Carvalho, 2011). However, they bring their mobile phone, their MP3/MP4 player,

or their Sony PSP. Teachers must learn how to create resources that can be accessed by their students' mobile devices.

We think that five main topics must be focused on when it comes to ICT programs: i) learning in the 21st century, as the contextual framework for all other topics; ii) evaluation of online information; iii) creating resources that foster web exploration, such as Treasure Hunt and WebQuest; iv) publishing and interacting in Web 2.0, such as through Google Sites, Podcasts, and social networks; and v) mobile learning. These five topics will enable the teacher to be updated and capable of teaching his/her students using ICT.

LEARNING IN THE 21ST CENTURY

For centuries, being literate has been defined as being able to read and to write. Although those core abilities are crucial in learning, they are no longer enough to ensure understanding (Richardson, 2006). Consumers of Web content need to be editors as well as readers. Anyone with access to Internet can publish without any prior review. This requires that teachers teach their students to become increasingly active consumers of that information instead of just accepting it as legitimate.

In order to truly take advantage of the power of the read/write Web, we must be literate in the sense of publishing (Richardson, 2006). We must be able to work with others in virtual environments. Writing is no more limited to text in a multimedia society. It is possible to combine many forms of writing into a process of rip, mix and learn. Siemens & Tittenberger (2009) refer that our learning and information acquisition is a mashup. Knowledge is a function of connections and understanding is the emergent shape of the network (idem).

We must know how to manage the information we consume. Web 2.0 can support these literacies (Richardson, 2006). The classroom of the Read/Write Web is of collaborative and individualized learning as well as of active participation of class members. The classroom is characterized by the continuous process of creating and sharing content. By inviting students to become active participants in the design of their own learning, we teach them how to be active participants in their lives and future careers (Richardson, 2006).

Teachers must start to see themselves as connectors, not only of content but of people (Richardson, 2006). They also need to collaborate with their students as well as with each other. They must begin to see themselves more as learners alongside their students. They need to think themselves as coaches who model the skills that students need in order to be successful and motivate them to strive for excellence.

Siemens (2005) stresses that "our ability to learn what we need for tomorrow is more important than what we know today". The author reports a vital skill: the ability to plug into sources in order to meet the requirements of new knowledge. Learning is the process of creating networks (Siemens, 2006). Connectivism is driven by the understanding that decisions are based on rapidly altering foundations. The idea of connectivism in learning is very interesting and pertinent however, we do not consider it a learning theory as the author refers. The increased complexity of our world does not permit any one individual an accurate understanding of the entire scope of a situation, field, or subject. We rely on connected specialization – where we increase our competence by adding specialized functionality to our network (Siemens, 2006).

EVALUATION OF ONLINE INFORMATION

As everyone can publish online, it is important to remember students that evaluating online information is necessary. Criteria for evaluating information online are presented, based in Alexander & Tate (1999), Schrock (2002), Richmond (2003), Treadwell (2006), and Jonassen (2007). The Web becomes a source of content for teaching and learning. Concepts such as quoting and plagiarism are focused, as well as standards for writing references.

After this important step a new one emerges: the construction of activities based on the information online such as Treasure Hunt and WebQuest.

CREATING RESOURCES THAT FOSTER WEB EXPLORATION

Usually we introduce Treasure Hunt and WebQuest. We prefer to start exploring the Treasure Hunt, followed by its creation. It is simpler than WebQuest and is very useful for guiding students to learn about a topic.

Students learn the importance of the Introduction to motivate the target audience. The sequence of questions regarding the topic with web links, and finally how the students will submit their work (table 1), for example, sending it by email to their teacher.

Table 1: Structure of a Treasure Hunt

Treasure Hunt	Description
Title	Target audience The author's name Author's e-mail
Introduction	To motivate the students about the topic.
Questions	Under each question, the Web links to find the information.
Last remark	To inform the students how to submit their work

In my classes, I suggest that my students post their Treasure Hunt in their blog or in another Web 2.0 tools, such as Issuu. This way, they can create a Treasure Hunt easily.

Afterwards, students are invited to analyze a WebQuest using a grid. The students learn a lot when they have to create a challenging WebQuest. It is very demanding and time consuming because everything is explicit especially all steps of the Process, and in the Evaluation with the self and peer evaluation grids.

A WebQuest contains five components: Introduction, Task or Tasks, Process, Evaluation, and Conclusion (Dodge, 1999a).

Table 2: Structure of a WebQuest

WebQuest	Description
Title	Target audience The author's name Author's e-mail
Introduction	To motivate the students about the topic.
Task (s)	The task is the single most important part of a WebQuest. A well designed task is doable and engaging, and elicits thinking in learners that goes beyond rote comprehension. Dodge (1999b) creates a WebQuest taskonomy, i. e., a taxonomy of tasks.
Process	Describes all steps to achieve the task or tasks.
Evaluation	Indicates how the product and the students will be evaluated. Questionnaires and grids help this evaluation for self and peers evaluation.
Conclusion	Presents what the students gain in solving the WebQuest and a new challenge is proposed: a new website, a new question, a game, …

According to Dodge (2007) a real WebQuest has the following attributes:

-"is wrapped around a doable and interesting task that is ideally a scaled down version of things that adults do as citizens or workers;

- requires higher level thinking, not simply summarizing. This includes synthesis, analysis, problem-solving, creativity and judgment;

- makes good use of the web. A WebQuest that isn't based on real resources from the web is probably just a traditional lesson in disguise. (Of course, books and other media can be used within a WebQuest, but if the web isn't at the heart of the lesson, it's not a WebQuest);

- isn't a research report or a step-by-step science or math procedure. Having learners simply distilling web sites and making a presentation about them isn't enough;

- isn't just a series of web-based experiences. Having learners go look at this page, then go play this game, then go here and turn your name into hieroglyphs doesn't require higher level thinking skills and so, by definition, isn't a WebQuest."

Students were required to check the WebQuest developed in the WebQuest evaluation rubric (Bellofatto et al., 2001) and the Fine Points Checklist. With our experience, we realized that teachers with several years of teaching experience understand better what to write on each WebQuest component, however, they tend to propose a task similar to what they teach. It takes time to understand the idea of a challenging task. The younger teachers or those with no teaching experience have difficulties in developing the Process and the Evaluation (Carvalho, 2003; 2006) and thus, particular guidance is needed.

PUBLISHING AND INTERACTING ON THE WEB 2.0

The appearance of Web 2.0, an expression proposed by Tim O'Reilly (2005), changed the way we can publish and connect people and ideas. The Web 2.0 tools are easy to use because they are user friendly.

Publishing online became as simple as writing on a word processor. The RSS feeds allow the user to subscribe and to automatically receive information regarding new posts in blogs, journals news, Flickr images, podcasts or other new materials.

The Web 2.0 enables social networks such as Facebook, Linkedin, MySpace, Orkut, hi5 (Bacon, 2009). There are a myriad of tools. The most commonly used are blogs, wikis, podcasts, Flickr, YouTube, Delicious, Google Docs, Google Sites. Now we focus on blog, Google Sites and podcasts.

A blog is useful as a first tool to post small messages, linking to thematic websites or events, to videos for example on YouTube, to images, to synthesize readings, etc. It is used as an e-portfolio (Carvalho, 2006).

Google Sites is used to create students' websites. For example, to create a personal website or a website to support activities, such as WebQuest, exercises and links regarding a subject.

Podcasts are also very useful. We start with audio podcasts, using the Audacity software, the students learn to upload the mp3 files to MyPodcast (Carvalho et al., 2009). Then, they also learn to create enhanced podcasts. It combines images, text and voice as an automatic presentation slide, and a screen cast in Jing software. Vodcasts can be created with MovieMaker. All these podcasts can be uploaded by students to their portable devices thus allowing them to learn whenever they wish, even when on the move.

MOBILE LEARNING

There are conceptualizations of mobile education that define it in terms of its technologies, its devices and its hardware (Kukulska-Hulme & Traxler, 2007; Moura, 2010). Such a definition is technocentric. Winters (2006) identified four perspectives on mobile learning:

-the *technocentric* – this perspective is dominant in literature. It is viewed as learning using a mobile device;

- *relationship to e-learning* – this perspective considers mobile learning as an extension of e-learning;

- *augmenting formal education* - the perspective that regards the place of mobile learning in relation to all forms of traditional learning, not only classroom;

- the *learner-centered* perspective emphasizes the mobility of the learner. "Learning that happens when the learner is not at a fixed, predetermined location, or (…) when the learner takes advantage of learning opportunities offered by mobile technologies" (O'Malley et al., 2003 apud Winters, 2006, p. 6) . Traxler (2007) considers that m-learning integrates any and all the features presented by Winters (2006).

More recently, the authors emphasize the process in m-learning. Sharples et al. (2009) characterized mobile learning as the processes (personal and public) of coming to know through exploration and conversation across multiple contexts, amongst people and interactive technologies. Pachler et al. (2010) described that "mobile learning is not about delivering content to mobile devices but, instead, about the processes of coming to know and being able to operate successfully in, and across, new and ever changing contexts and learning spaces" (p. 6). The definition proposed by Mobile Learning Network about m-learning focuses on "the **exploitation of ubiquitous handheld technologies, together with wireless and mobile phone networks, to facilitate, support, enhance and extend the reach of teaching and learning**" (MoLeNet, 2011). Mobile learning can occur in any location, at any time, and in transit.

Mobile learning can be seen in terms of the learners' experiences with an emphasis on device ownership, informality, movement and context that will always be inaccessible to conventional e-learning (Kukulska-Hulme & Traxler, 2007). It increases learning flexibility for students.

Kukulska-Hulme & Traxler (2007) refer the work of Naismith et al. (2004) who have demonstrated that mobile technologies can relate to six different types of learning:

- behaviourist-type - the quick feedback or reinforcement element is facilitated by mobile devices;
- constructivist – immersive experience are provided by mobile investigations or games;
- situated, learners can take a mobile device out into an authentic context, or use it to access information while moving around an environment in a specially equipped location such as a museum;
- collaborative, mobile devices provide a handy additional means of communication and a portable means of electronic information sharing;
- informal and lifelong learning, mobile devices accompany users in their everyday experiences and become a convenient source of information or means of communication that assist with learning, or records it on the go for future consultation;

- Support, or coordination of learning and resources – activities that teachers and learners engage in at various times during the day.

Tasks suited to mobile learning involve data collection, tests and quizzes, consolidation of learning, personal reflection and skills acquisition (Kukulska-Hulme & Traxler, 2007).

> "Whether they are welcome right now or not, mobile devices are finding their way into classrooms in children's pockets, and we must ensure that educational practice can include these technologies in productive ways" (Naismith et al., 2004, p. 36).

Our students must learn how to use software in order to create interactive activities and websites to be accessed using their mobile devices.

MASTER STUDENTS' WEB 2.0 PRACTICES AND REACTIONS TO MOBILE LEARNING

In January 2011, we inquired Educational Technology Master Students as to their presence online using Blog, Twitter, Facebook, etc; what kind of Web activities they use with their students, what kind of mobile devices they have, if they would like to learn to create interactive activities for mobile devices and if they think that mobile learning will be the future in schools. The questionnaire was completed during a face to face session. During this academic year we are not teaching.

Sample characterization

Seventeen students answered the questionnaire: 10 females and 7 males. Their age ranged from 23 to 50 or more years (table 3). The mode is the range 30 to 39 years with 9 respondents.

Table 3: Sample age (n=17)

Age range of respondents	f
23-29	3
30-39	9
40-49	2
≥50	3

It is possible to identify two groups in what concerns teaching experience, the first one with 9 respondents with 4 to 7 years teaching experience and the second one with 8 respondents with 14 to 34 years of teaching experience (table 4).

Table 4: Years of teaching experience (n=17)

Years of teaching experience	f
3	3
4	1
5	2
6	2
7	1
14	2
15	1
18	1
23	1
29	2
34	1

These students have a different teaching background. Five of them teach ICT and other subjects such as Computer Science (4), Visual and Technological Education (2), Sciences (2), Portuguese (1), Musical Education (1), Plastic Expression (1), Mathematics (1), Geography (1), Biology and Geology (1), Geometries (1), Pharmacology (1) and Pharmacotherapy (1). All students possess Internet connections.

Students' participation in Web 2.0

All students have a blog (table 5), but it was mandatory for one of the Master courses. All of them except one, are members of a social network, such as Facebook (13), hi5 (2), and MySpace (1). The e-learning platform is used by 13 respondents to support their classes. Twitter is used by 4 students, and 2 have a website.

Table 5: Students' presence online

Students participation on the Web	f	%
Blog	17	100
Twitter	4	24
Website	2	12
Facebook	13	76
Another social network	3	18
e-learning Platform	13	76

In their classrooms, 16 respondents use tools to publish students' work online (table 6). Unfortunately, all other resources and tools are rarely used. They use interactive exercises (14),WebQuests (11), and only a few use vodcast (3) or send SMS to students (5).

Table 6: Resources and tools used by Master Students in their classrooms

Frequency In the classroom they use …	Frequently f	Rarely f	No f	I do not know it f
Treasure Hunt	0	1	14	1
WebQuest	2	9	5	0
Interactive exercises (HotPotatoes or another)	6	8	3	0
Podcast	0	6	11	0
Vodcast	1	2	12	2
Screencast	0	3	13	1
Tools to publish works online	11	5	1	0
Send SMS to students	1	4	12	0

Most respondents do not use Treasure Hunt (14), Screencast (13), Vodcast (12), Podcast (11), nor do they send their students SMS (12). Two respondents did not know what a vodcast was, and one indicated screencast and another Treasure hunt.

Most respondents (13) mentioned that they have activities online for their students (table 7). Two referred that they do not have time to do so. One indicated that she would like to but she does not know how, and another said that her students do not have access to the Internet.

Table 7: Carrying out online activities

Activities online for your students	f	%
Yes	13	76
I do not have time	2	18
I would like to, but I do not know how to do	1	6
Other	1	6

Those who answered that they have online activities for their students indicated HotPotatoes or other interactive exercises (4), exercises in the LMS (3), Exercises in Google Docs, searching online, posts in blogs, challenges but it was not indicated what kind, and activities sent by e-mail. This list was a little bit disappointing.

Portable devices

They were asked about their portable devices (table 8). All of them have a laptop and a cell phone. Most of them have MP3 players (10). The MP4 player and the PSP is only owned by 5 respondents.

Table 8: Students ownership of mobile devices

Ownership of mobile devices	f	%
Laptop	17	100
MP3 Player	10	59
MP4 Player	5	29
PSP (PlayStation Portable)	5	29
Cell phone	17	100
Another mobile device	4	24

Four students indicated another mobile device such as GPS, digital audio recorder, PDA, iPad, and iPhone. They use their cell phones for calling (15), sending and receiving SMS (14), alarm clock (15), calendar (3), taking photos (1) and two to access the Internet daily (table 9). Seven do not use their cell phones to access Internet and eight do so but not often. Twelve respondents have Internet access as they reported.

Table 9: Uses of their cell phone

Cell phone is used for …	Daily	Weekly	Rarely	Do Not use
Send and receive SMS	14	2	1	0
Send and receive MMS	0	2	9	6
Calling	16	1	0	0
Alarm	15	0	2	0
Playing games	0	2	7	8
Calculator	0	5	8	4
Calendar	3	7	3	4
Listening music	0	4	7	6
Taking photos	1	4	11	1
Making movies	0	1	11	5
Internet access	2	2	6	7

They seldom take photos (15), use the calculator (13), make movies (12), listening to music (11), sending and receiving MMS, calendar (10), and they play games (9). Six respondents have free SMS.
The students were asked if they would like to receive on their cell phone: a paper to read, reminders of due dates or class alterations. All of them were receptive to class alterations, 14 to reminders of due dates, and 9 to receiving a paper to read. Only 3 students had used the cell phone to study.
They were asked if they would like to learn how to elaborate interactive activities or interactive exercises for mobile devices. The majority of students (71%) would like to learn to elaborate interactive activities or interactive exercises to mobile devices, but 29% indicated that they could not identify any relevance in learning that (table 10). No one knows how to do so.

Table 10: Learn to do interactive activities to mobile devices

Would you like to learn to do interactive activities or exercises for mobile devices?	f	%
Yes, I would like	12	71
No, there is no relevance in knowing that	5	29
I know how to do it	0	0

Reactions to mobile learning
They were asked if they think that mobile learning will be available in schools. More than half of the students (53%) considered that mobile learning will be available at school soon (table 11). One student did not answer.

Table 11: Mobile learning available in schools

Years of teaching experience	Number of teachers		Yes, mobile learning will be available in schools		No, m-learning will not be available in schools	
	f	%	f	%	f	%
3 to 7	9	53	3	18	6	35
14 to 29	7	41	6	35	1	6
34	1	6	-	-	-	-

Master students with more years of teaching experience (from 14 to 29 years) are all receptive to mobile learning except one. The majority of younger master students are not so receptive to the technical evolution of learning in schools. This result was not expected. We expected younger teachers to be more receptive to mobile learning than older ones.

CONCLUSION

We propose five topics in educating teachers in ICT. All of them are related and contributed to an increasingly skilled teacher for the 21st century. We start with a framework regarding learning in the 21st century, focusing on the evolution of the concept of being literate; the teacher as a students' guide supported by Web 2.0 tools; and the relevance of connectivism. Then, the evaluation of the information online and the concepts of quoting and of plagiarism will be addressed. This topic will be followed by the analysis and creation of a Treasure Hunt and/or a WebQuest that foster web exploration. The fourth topic pertains to publishing and interacting using Web 2.0 tools, such as Google Sites, Podcasts, and social networks. Finally, we focus on mobile learning and its importance nowadays.

An inquiry was conducted to the Educational Technology Master students about their presence online, what kind of Web activities they used with their students, their opinion regarding the future of mobile learning in school, if they would like to learn how to create interactive activities for mobile devices, and what kind of mobile devices they possess. All of them with the exception of one belong to a social network. In what concerns the use of resources and web 2.0 tools in the classroom, they use them, but most of them rarely. The majority of respondents (76%) have activities online for their students, but we expected more interactive activities. They have mobile devices, but only 53% believe in mobile learning in school. They are also receptive in learning how to create interactive activities or exercises to mobile earning (71%). These respondents must learn about interactive activities based on online resources to use them in the classrooms frequently.

Abstract: The world is experiencing a rapid development, in which technology is directly or indirectly present in most common activities. The school is part of this world and it must fulfill its mission of contributing to the formation of citizens, being open to incorporate new habits, attitudes, perceptions and demands. However, school still has many difficulties in working with audiovisual materials, insisting on teaching, basically, with the spoken and written word. From the beginning of the expansion strides of the digital era, the classroom seems unable to keep up with the changes of the virtual world. On the contrary we see students increasingly dispersed and tuned up with new technologies and virtual tools. Students are always ready for multimedia but their teachers, in general, are not. Even when advanced technologies are available in schools, teachers feel insecure due to the changes that technologies represent in teaching and learning processes. They are, indeed, afraid of revealing their difficulties before the student and, therefore, maintain an attitude of detachment. Thus, schools need educators who organize more meaningful activities than lectures. They need to be mediators of knowledge rather than informants. The new Brazilian school must be built as an institution that can effectively work with a multiplicity of world views. In Environmental Education (EE), the use of modern technologies represents an advance, since the integration of audiovisual resources allows the knowledge of different environments and their specific problems. Therefore, in this work, we investigated how the inclusion of audiovisual resources occurs in school, especially when the focus is environmental education (EE). In Brazil, according to National Policy on EE, defined by Federal Law 9,795/99, EE does not have the rigidity of a discipline but has to be articulated with different areas of knowledge. In this way, it becomes necessary to develop processes of teaching and creative learning that are related to projects of social transformation. Moreover, educational technologies such as videos, films and internet, using images, texts and sounds, can offer much innovation and dynamism in these processes. For this research we used qualitative methodology, through questionnaires (in this case, semi-structured). We interviewed an EE group of twelve teachers from a public high school, located in the west side of Rio de Janeiro city, near the Pedra Branca State Park. Despite the excellent work developed by the EE group from "CIEP-165 Brigadeiro Sérgio Carvalho" in the region, including transdisciplinary approach, the majority of the group does not use audiovisual resources in their classes.

Keywords: Audiovisual materials; environmental education; school context.

INTRODUCTION

Much is said about the need to incorporate the vast Brazilian audiovisual production to the everyday experiences of our public schools. However, elementary and high school teachers, along their career path, generally do not have any specific training for this.

Despite that the development of audiovisual means and the diffusion of hypertexts are managing to break the central role imposed by the didactic book and by the conservative model of transmitting knowledge, the school, mostly, is still closed to these new types of experiences in the name of a tradition that delegitimizes the knowledge acquired from social practices (Martín-Barbero, 2003).

Teacher-focused teaching models are still predominant, in spite of the theoretical advances in search of changes for the sake of the bi-directional teaching-learning process and the pedagogic proposals that encourage greater interaction. If, on the one hand, the students are ready for multimedia, on the other, their teachers, generally, are not. Many are even afraid to reveal their difficulties before the student and, as a result, maintain a repressive and controlling structure, preferring to conserve their *modus operandi* due to the insecurity that the changes represent.

Martín-Barbero (2001) stated that the older generations should confront the fears that they feel in the face of the transformations that the contemporary brings to culture and to modes of communication, confronting the

future and allowing it to be born, and not remaining imprisoned to the false imaginary of the past as a lost paradise.

One of the generalized complaints of the schools and universities is that the students can no longer tolerate the way teachers give classes. Students complain about the boredom of listening to teachers in the front for hours, the rigidity of the schedule and the lack of meaning that class content has on their lives (Moran, 2004). Technology could, at least, offer greater stimulus to the classes, but, when used, it is, generally, more restricted to complementing the teacher content, as a demonstrative illustration, rather than creating new didactic challenges.

According to Moran (1995), the school needs educators that organize significant activities more than descriptive classes, so that they, effectively, are mediators of knowledge and not informers. It is a necessary cultural change, more complex, with little perspective of being carried out, at least in formal education, to the degree that the teacher-educator courses have not undergone the changes that transform the professional paths of the future educators.

In this context of transformation, the new Brazilian school needs to be thought of as an institution that can effectively work with multiple world visions. According to Pretto (2005), to work with this perspective means to consider audiovisual language as a language of the society of the next century. Observing the behavior of school-aged children which have already been created through avid contact with video games, televisions and computers could be meaningful in understanding some of the reasons for the failure of today´s schools and could also point out some elements to overcome these failures.

In this way, while technology is ever-seductive with novelties and facilities, it is not autonomous in that. Nothing can happen without the pedagogic direction given by teachers. In school, as in any other environment, it is necessary to use methodology. The more one studies about the use of technology in the educational environment, the more evident the premise that without the main actors, student and teacher, nothing is accomplished and nothing in the learning process is changed.

As a result of all that has been mentioned, the idea of this study stemmed from the principal interest in investigating how the audiovisual resources are being inserted into the educational environment, specifically when the focus is environmental education (EE) which, according to National EE Policy defined by Federal Law no. 9,795/99, does not have the rigidity of a discipline and, therefore, can be approached articulated to diverse areas of knowledge.

EE AND NEW TECHNOLOGIES

With the elaboration of the National Curriculum Parameters (NCP), in 1997, the "environment" was included in one of the transversal themes. The environment as a transversal theme is postulated within a curricular concept of interdisciplinary knowledge construction and aims the consolidation of citizenship, pointing to contents linked to the daily lives and interests of the majority of the population. Transversality proposes to surpass discipline specialties, thus making an environmental theme an issue, in the area of knowledge that has no explicit borders (Araújo, 2005).

The interpretation conferred to curricular integration in the elementary and high school is not the same. In Elementary Education, the option is transversal themes; on the high school, interdisciplinarity (Lopes, 2002). To express the interdisciplinary focus in high school, the NCP organized the three areas with their respective disciplinary knowledge: Languages, Codes and Related Technologies; Natural Sciences, Mathematics and Related Technologies; Human Sciences and Related Technologies. The division into areas is based on the union of the knowledge that share study objects and, therefore, communicate more easily, creating conditions so that the school practice develops in an interdisciplinary perspective.

As such, the NCP are references of quality for elementary and high School in the country, elaborated by the Federal Government. One of the objectives is to subsidize the elaboration and re-elaboration of the curriculum, bearing in mind a pedagogic view in function of the citizenship of the student and a school where one learns more and better. Furthermore, NCP guarantee that children and teens have access to the knowledge that is necessary to integrate into a modern society as conscious, responsible and participating citizens. Also, in this official governmental document, is that technology should serve to enrich the educational environment, propitiating the building of knowledge through the active, critical and creative performance by both students and teachers. It also establishes that the citizenship education requires that social questions are presented so that students reflect and learn, seeking didactic treatment that contemplates their complexities and dynamics.

If the proposal of EE is to form the youth with a critical consciousness about environmental and social problems, then it becomes necessary to develop creative teaching-learning processes linked to projects of

social transformation. Therefore the educational technologies such as educational videos, films and the internet, could offer much innovation and dynamism in this process.

Different didactic material focused on environmental education is increasingly being produced. In the case of audiovisual material, an important evaluation was realized by Costa and Trajber (2001). The authors stated that it was necessary to investigate about the reception and real use of these materials in the classroom. They tell about a friend, a video-maker, who received an environmental video award for a Project on Brazilian fruits, and then watched numerous environmental films and was thinking about who, in fact, would watch all of that? Who will receive them? How are the audiovisuals perceived, felt and interpreted? What kind of work do the educators do with these?

Therefore, the idea of this study is also to verify if there are many teachers using the vast didactic audiovisual material that is linked to EE; how have the teachers made use of them in the classroom; and if the mode of use is only focused on information and the transmission of knowledge without taking into consideration the different meanings that the material can assume in the school community. Additionally, it is to verify if they have produced new material together with their students.

EE CONCEPTS AND PRACTICES IN THE SCHOOLS

For Pérez Gomez (1995), school is extremely conservative. As any other social institution, it develops and reproduces its own culture. The traditions, customs, routines and inertias that the school stimulates and endeavors to conserve and reproduce, clearly condition the type of life that it develops and reinforces the enactment of the values, beliefs and expectations linked to the social life of the groups composing the school. The EE should be understood as an instrument of social transformation to achieve environmental change and a society ecologically prudent and socially just. According to Quintas (2004), EE should be critical in that it discusses and explains the contradictions of the current model of civilization, of the relationship between society and nature and of the social relationships it establishes. Transformer, because by bringing into discussion the character of the civilizing process under way, it believes in the capacity of humanity to build a different future from the construction of another present and, thus, establishing new relations of human beings among themselves and with nature. It is also emancipatory, by taking freedom as a fundamental value and seeking the production of autonomy of subordinate groups, oppressed and excluded. As per Tozoni-Reis (2005), although EE is known as a necessity of contemporary society, it is not a mode of education whose principles, objectives and education strategies are equal for all those that practice it. This means that there are conceptual differences that result in the construction of different environmental educational practices. For this author, there are conceptual differences of EE that can be synthesized in some major groups: (1) those who believe that EE is tasked to promote changes in environmentally inappropriate behavior - the EE of discipliner and moralistic backgrounds as "environment training"; (2) those who think EE as responsible for the transmission of technical-scientific knowledge on environmental processes - the EE focused on the transmission of knowledge; (3) those who think EE as a political process of appropriating critical and reflective of knowledge, attitudes, values and behaviors that are intended to built a sustainable society from a environmental and social viewpoint - the EE transformer and emancipatory.

In according to Tozoni-Reis (2005), EE is, therefore, not a modality of education whose educational principles, objectives and strategies are the same for all those who practice it. This means that there are conceptual differences resulting in the construction of different environmental education practices. Thus, there is a great need to reflect on EE knowledge that is being produced in the schools, beginning with the insertion of the audiovisual material used by the teachers in the classroom. For example, if the teacher presents an EE concept centered on the transmission of knowledge then it is possible that he looks for didactic material that is focused only on informing, without trying to provoke, in the students, a critical, transforming and emancipating posture relative to the world in which they live (Loureiro, 2004).

It is true that production format diversity is always welcome, but it is necessary to know if the way in which they are used corresponds to the adequacy of the material – nothing against the creativity that makes the material versatile, but against inadequate use of the material.

CONTEXTUALIZING THE SCHOOL WHERE THIS STUDY WAS DEVELOPED

The school chosen for this study was CIEP-165 Brigadeiro Sérgio Carvalho, located on Rio da Prata, a suburb of Campo Grande, in the eastern zone of the City of Rio de Janeiro, in Brazil. CIEP-165 has an average of 2,000 (two thousand) high school students, teens and adults. The teaching body is comprised by 100 (one-hundred) teachers working with the 46 (forty-six) classes, graduated by the school annually. This teaching modality works only in 3 shifts and has a representative number of the region's inhabitants.

Rio da Prata is one of the gateways to the Pedra Branca State Park. The Pedra Branca State Park, the largest urban forest in the world, is located in Eastern Rio de Janeiro. It was created by State Law No. 2,377, on June 28, 1974, incorporating all of the hillsides of Maciço da Pedra Branca 100 meters above sea level. It covers 12,500 hectares (125 square kilometers), and is delimited by numerous neighborhoods of the East Zone and the Jacarepaguá area. Maciço da Pedra Branca has an important hydrographic network, with a part of it contributing to the supplying of water to Rio da Prata. The region is lacking in basic infrastructure, the result of a disorganized occupation process. There is a large population contingency in the situation of social and economic exclusion.

In the school, there is a multidisciplinary EE team formed by twelve (12) teachers. They meet periodically to trace strategies of action involving not only the school community but also the surrounding community, environmental movements, resident associations, municipal schools of the region, among others.

CIEP-165 Brigadeiro Sérgio Carvalho was chosen for this study because of its history, as it functions as a facilitator pole for the EE actions of the region. Since 2000, when the school officially became the Citizenship Movement Reference Center for the Waters of Campo Grande, and by the Regional Counsel of Architecture and Engineering of Rio de Janeiro (CREA/RJ), it has fought to improve the quality of life. Numerous EE activities have already been developed with the surrounding municipal schools, with the mass participation of the school communities and neighboring regions.

An important example of the partnership between the local schools was the I Environmental Forum of Rio da Prata, in 2007, where an educational video about the region was released, students of the city schools and CIEP gave presentations and a round table with local community representatives, environmental institutions, government representatives, besides groups of projects about the themes of "Water and Sanitation"; "Environmental Education"; "Urbanization"; "Local Agriculture" "Pedra Branca State Park" and "Health and Environment". Based on the themes that were discussed in the projects, a document was elaborated in which the quality of the water was indicated as being a serious environmental problem of the region.

The unfolding of the projects that were developed at the school in 2007, were announced on the site of the Secretary of Education of the State of Rio de Janeiro (SEEDUC/RJ). Consequently, the "Salto para o futuro", which integrates the grid of School TV (channel of the Ministry of Education), entered into contact and filmed a program about environmental education in Brazil for the channel, and was aired in 2008. CIEP-165 was also one of the schools selected to implant the "School Agenda 21", a project sponsored by SEEDUC/RJ together with the Environmental Secretary of the State of Rio de Janeiro (SEAM/RJ). In addition, two projects with an environmental focus were approved for financing by *Foundation of Support to Research of the State of Rio de Janeiro (FAPERJ).* One entitled "For Investigative Education and in Favor of Transdisciplinarity", announcing the improvement of science education, coordinated by a researcher of the Oswaldo Cruz Foundation, and another "Environment and Citizenship: Ways of Popularizing the Scientific Knowledge Developed at the Universities", announcement for popularizing the sciences, coordinated by a professor at the State University of Rio de Janeiro (UERJ).

AUDIOVISUALS, CIEP-165 AND EE

There are numerous definitions for the word audiovisual. In an extremely open way and one that is not coherent with the name, usually, in the centers of information, audiovisual is considered as the part of the inventory that, obviously, deals with audio and/or visual and does not have the format of a book. It doesn´t matter if the sound and image are together or separate and, sometimes, if the support has or does not have words included.

Some authors consider audiovisual as a polyphone of languages, images, musical sound, words and writing. Advancing along this line of thought, the audiovisual does not represent only two different paths – the visual and the auditory – of access to knowledge. It is seen as multidimensional and plurisensorial, integrating other sense organs in sophisticated forms of sensorial communication (Bethônico, 2006).

The teachers composing the EE group of the school were the object of this study. The type of material that was considered to be audiovisual was not delimited. Each teacher was free to choose. Within the EE group of CIEP-165, made up of twelve (12) teachers, only three (3) of them used audiovisual material in their classrooms. Two (2) of them were chemistry teachers and the other a Portuguese Language teacher. It is important to emphasize that the Portuguese Language teacher, Ana Beatriz, entered the EE group at the school in 2007, the chemistry teacher, Antônio Cláudio entered the group in 2009 and teacher Jamilson, also of chemistry, entered in 2004.

Among the teachers that did not use the audiovisual resources, they claim, mainly, not having the time necessary to prepare a more elaborate class; lack of infra-structure in the school as there were no projection rooms (the school has only one 29" TV and a data-show and it is necessary to schedule time), much time is

lost setting up the devices, also it is frequently necessary to think out all of the details, even if the school has an extension; a lack of intimacy with the resources (a real lack of experience); a lack of knowledge of all that exists in the video market and the absence of an "instruction manual" explaining how the videos should be used on the classroom.

To realize the study a qualitative method, a semi-structured interview, was used. The questions were about the following: Which audiovisual materials are used in the classroom? Are the proposed objectives achieved? How is the audiovisual material selected? What are the criteria used to select the material? In which manner is the pedagogic domain of audiovisual language optimized in environmental education both in and out of the classroom? Does the use of audiovisual material in EE facilitate the production of knowledge related to environmental questions, stimulating greater participation and intervention in the local reality? What were the difficulties with the school infra-structure on the day of use?

CIEP-165 AND THE TEACHERS THAT USE AUDIOVISUALS IN EE

The principal excerpts of what was said by the three (3) teachers who use audiovisual resources in EE were reproduced below, seeking not to alter the original content of same.

The chemistry teacher, Antônio Cláudio, not long ago, acquired a DVD player-recorder, making it possible to generate his own didactic material, taping reports, advertising and documentaries directly from the TV. In this way he can easily insert different material into the classroom. He said that he has been working with images since 1985 and has observed that technology advanced during these last years, from the video-cassette to the computer. He has also gained the freedom to edit images that he never even dreamed of at the beginning of his career. He has also noted that, pedagogically, his performance has suffered great variations. He adds that he does not have a single criterion for selection, at times he records everything (he has a 180 GB external HD), cartoons, films, TV-journals and others. He has these files readily available and when a theme is brought up or proposed in the classroom, he uses them. These files are available to the students in computer labs and they go off on their searches and constructions, and it is their task to reorganize the presentations in a more didactic manner relative to the subject that they are working on. He states that he has already presented some projects produced by the students in other Institutions. He adds that one was presented at State University of Rio de Janeiro (UERJ), during the week of visual education in 2007, where the students revisited the theme of water. In 2008, his project was among the 100 best on "Who reads newspapers, knows more", from the newspaper "O GLOBO", with his presentation of "Rio 45 Graus", where the students showed the transformations caused by global warming in the vicinity surrounding the school. He also gave a presentation at Federal University of Rio de Janeiro (UFRJ), developed by the students, called "We don´t only want food", where the local assets were demonstrated via photos, seeking to construct the concept of environmental assets. He believes that these presentations, in other Institutions, have motivated great transformations in the students. The teacher further adds that there really are infra-structure problems at the school.

Teacher Jamilson searches the internet to select material, using films that can explore environmental questions. His objective is to better exemplify the class with the material used. He states that he is able to achieve his objectives, as the classes are more dynamic and the students pay greater attention. His criteria for selecting the material are dependent on the theme centered on in class. He selects the material according to the planned theme, always concerned with previous testing and watching to avoid any last-minute problems. Mr. Jamilson says that it is not enough to show a film and then not get deeper into the idea presented. The tool of audiovisual material, if worked well, can be a great motivator, resulting in more effective local participation. He states that there are many difficulties with the school infra-structure, as most of the schools do not have the appropriate rooms for constant audiovisual use and does not have sufficient equipment for the use of these tools making it necessary to reserve the room.

The teacher Ana Beatriz uses, for example, movies such as "A Carne é Fraca", "A Maravilhosa História da Batata", "Os Outros", and "Ilha das Flores". The latter, a short-film, in her opinion, can be used in numerous activities. She says that it is almost poetry, as it cites excerpts from "Cancioneiro da Inconfidência" by Cecília Meirelles and broaches polemic themes. She works with the production of text after a discussion in the classroom. She adds that she always stimulates the discussion as she doesn't want her students to continue as the "manipulated masses" and wants them to have a critical view of the world. The teacher believes that she achieves her objectives with inserting audiovisual material in themes linked to EE. She adds that, according to the age group of her students, she plans the class beforehand, principally because she still uses VHS films. Her criteria for selection of the material used in the classroom are those that use language that is easily accessed by those she is working with. She states that, after a film, the students like to have discussions, to remember the ideas, the funny, sad or interesting scenes. The films are a great help. She

completes that the school does not have a video-library that is adequate for the reality of a site that attends to the needs of the teacher.

RESULTS AND FINAL CONSIDERATIONS

The demand for environmental video is growing. The opportunity to look at the environment in which we live, that which surrounds us, as if for the first time, a sensitive and critical view that permits the evaluation of what is and what is not good (Rother e Tomazello, 2004). Any and all images offer the possibility of multiple and complex readings. Video-graph and film languages are, markedly, moving images. They are valuable instruments in working complex themes with the students, as they allow one problem to be broached from various angles and perspectives.

Despite the exquisite work developed by the EE group of CIEP-165 Brigadeiro Sergio Carvalho in the region, with even a transdisciplinary focus, few of the group use audiovisual resources. None of those interviewed who use audiovisual resources have used the theme of the local environment as criteria, for example, of selecting a video. Only teacher Ana Beatriz cited the lack of a video-library that is adequate to the reality of the region. The objective of the three teachers interviewed is to induce reflection and generate debates from the videos. They perceive the strong vocation of the video as a motivator, according to Ferrés (1996).

Professor Antonio Claudio was one of the most experienced teacher in using new technologies in educational process. He stimulates his students to prepare their own materials based on collection that he provides, while teachers Ana Beatriz and Jamilson utilize audiovisual material that already exists in the market. Professor Jamilson says that if the audiovisual material was worked well, it can motivate a more effective local participation but he does not mention how to achieve that. Professor Ana Beatriz brilliantly manages to establish a link between the discipline Portuguese Language and EE, working with production of text prepared by students based on selected films that deal with socio-environmental issues.

In the schools, generally, the productions by the teachers are not systematized, registered in writing. Nonetheless, they can be shared orally and the sharing of this knowledge benefits the entire group. In the school it is necessary to guarantee a space for the socialization of this knowledge relating to the teaching-learning process of the environmental questions constructed by each teacher in the classroom.

The municipal schools of Rio de Janeiro received, in 2009, a TV with DVD-player to be installed in each classroom, possibly indicating an advance and the hope that audiovisual use increases. In the years 2008 and 2009, all of the teachers from the Municipal and State Education Network of Rio de Janeiro received laptops, which is a great step for the insertion of new technologies in education, including in EE. However, the teachers of elementary and high school need to have a specific formation. There is still, without a doubt, a long way to go.

Finally, it is important to emphasize that for audiovisuals to truly be a cognitive tool there should be an environment that is contextually rich in knowledge that gives support to the students. Despite that they are able to be projected with the objective of stimulating, sensitizing the students to the environmental theme, audiovisuals are a resource that can only inform and will not result in the learning through didactic material.

315 - Digital Literacy and the Construction of Meaning

Eliana Soares, Carla Valentini, and Cristina Pescador

Graduate Program in Education PPGEdu, UCS University, Caxias do Sul, Brazil
cristina.pescador@ucs.br

Abstract: The presence of educational laptops in the routine of students and teachers might contribute for the construction of innovative alternatives for the teaching practice, favoring collaborative networks to emerge in the development of concepts and socialization of knowledge. This reflection starts from the idea that the insertion of educational laptops, in a 1:1 model, should be firmly based on the concepts of cooperation, autonomy, criticism, and the construction of meaning. In that sense, digital literacy implies on the interaction in social networks that allow exploration and research, teaching and criticizing in a process of learning and knowing mediated by digital technologies. To do so, from the non-linearity that accompanies the communication flows emerging from these technologies, students and teachers are instigated to find new meanings, where reading and writing consist in sharing knowledge and opinions and not only an assignment to hand in.

Keywords: literacy, digital technologies, learning, social interaction

DIGITAL TECHNOLOGIES IN THE CLASSROOM

Schools and classrooms are being challenged by digital technologies, which – nowadays more than ever – permeate everyday lives in our society. Although the presence of digital technologies has been influencing education and society for many years, it seems that impact has not yet been noticed in the school context. Computers and communication technology can be seen in our students' and their families' everyday lives, in professional and commercial environments, but very scarcely in classrooms. What we actually see are computers isolated in a room especially designated for them – the IT lab – where students are taken to work or play with them. And the activities carried out in the IT lab in this context are not usually related to the learning process.

With that in mind, it would be fair to say that computers and digital technologies seem to have been underused in the school context. One of the reasons for this underuse is that their potential as means of communication and precursor of interactions and cooperation that can serve as a foundation for learning is not taken into account when planning the teaching-learning process.

Apparently there is also some kind of aversion to using digital technologies in the classroom. The activities proposed by teachers at school are time-consuming and teacher-centered, involving standardized exercises and problems to be solved, along with repetitive tasks, test taking, among many other actions that seem to never change in some teaching practices. Although a lot has been said about introducing technology in the educational context, not much has been done to actually include it in the classrooms, learning environments, students' cognitive actions, and teaching practices. And having state-of-the-art technology in the school with computer labs and interactive boards does not assure effective changes in the teaching-learning processes. Would it be enough to replace the old blackboards by interactive whiteboards? It is our assumption that much more has to be taken into consideration if we want to introduce technologies in schools' learning environment effectively.

In Brazil, as in many other countries, it is likely that within 5 years or so all the children studying in public schools will have laptop computers in their classrooms if we consider the ongoing public policies. That leads to a few questions that guide our study. What impact will that cause on learning processes and teachers' education? On teaching processes and on school culture?

This paper intends to reflect on digital literacy in the context of one laptop per child (1:1) from a pilot experience being carried out in a public school in the southern region of Brazil.

Inserting educational laptops in the 1:1 model

The Brazilian National Program for Information Technology in Education (Programa Nacional de Informática na Educação - Proinfo) has been increasing its actions in public elementary schools by introducing the project known as Um computador por Aluno – UCA (or internationally known as One Laptop per Child), 1:1, which started its first stage in 300 schools around the country. Currently, there are

other cities and towns joining the next stage of the project – now as a program – with many city and town halls purchasing the laptops and increasing the number of schools to use educational laptops in their classrooms. Within a few years it is likely that all public schools in Brazil should have this 1:1 situation in their classrooms.

This might be an opportunity to transform school practices, starting with qualification programs for the teachers and the engagement of students from public schools in practices that privilege interaction, cooperative-based learning and construction of knowledge, with laptops connected to the Internet. However such pedagogical movement is much longer and more complex than introducing laptops in the classroom and teachers' appropriation of the technology available with the equipment. Teachers' education programs are also concerned with the importance of pointing out the need for changing schools' political-pedagogical proposals, so as to align possibilities with the educational laptop to innovative pedagogical strategies, favoring collaborative networks to emerge for the development of concepts and socialization of knowledge.

If, in the past, digital technologies used to be secluded at the school's computer labs far away from the classrooms and from students' everyday practices and occasionally present in teachers' lesson plans, the situation of one laptop per teacher nowadays can somehow be like an unbalance of the order. All students can have simultaneous access to information and to instant messaging tools. New possibilities arise for learning, as well as new demands for teachers regarding their knowledge, lesson planning, and classroom management.

Introducing laptops as motivation to redimension educational practices towards digital literacy

As we introduce the educational laptop in the classrooms we should think of ways that go beyond simply using technologies as a resource to modernize current practices. They should be seen especially as a possibility of innovative practices that favor the development of cooperation, autonomy, criticism and construction of meaning. In the knowledge society (Castells, 1993), the teaching-learning process has to be focused on the full development of the individuals. To do that, it is necessary that they can appropriate the several forms of accessing information available in the context of this society, and that they can understand those forms, making sense out of them and interacting with their peers, building knowledge and being able to transpose it to their domain of action.

Introducing laptops as it is being proposed requires other kinds of languages to mediate the educational process from teachers and students, because directions and tasks will not be centered on the teacher and on written texts. When dealing with hypertexts, browsing on the Web and being active participants in social networks – all made possible thanks to the laptops - students and teachers are immersed in an interactive domain where new reading and writing practices are taking place.

The conception of using technologies is related to a concept of digital literacy that goes beyond the simple appropriation of how to use digital resources in an operational dimension. It is not enough to be able to read the codes of a language for an individual to be considered literate in the sense of using language for their social and cultural inclusion. Likewise, knowing how to use digital resources is not enough to transform that use in significative social and cognitive practices and actions.

Digital literacy – as we understand it – is related to the use of digital technologies that is both critical and aware in order to make sense of its use and make it relevant in the individual's being and acting in the world. According to that approach, the concept includes the use of digital technologies with a specific competence, significatively, understanding limits and potentialities in the context of social and educational practices. That means this use has to take place in such a way that the practice becomes meaningful in its domain of action. Such action domain includes searching for information, communicating and publishing while using the Web, in a responsible way and with a purpose.

Lévy (1999, p.17) defines digital literacy as a set of material and intellectual techniques, practices, attitudes, ways of thinking, and values that develop along with the growth of the cyberspace, as a means of communication that emerges from the worldwide interconnection of computers. So that children can enter a process of digital literacy, it is necessary that they have access to computers and that they take part in educational practices that require using IT according to that perspective.

In that sense, digital literacy implies in interacting in social networks that allow exploring and (re)searching, teaching and criticizing in a process where learning and knowing is mediated by digital technologies. And upon the non-linear feature that lies within these technologies, students and teachers face the challenge of finding new meanings, with reading and writing becoming an action of sharing knowledge and opinions and not only an assignment that has to be handed in.

As a result, digital literacy will make it possible for schools to become a place for social interaction. According to Xavier, schools should provide "digital literacy for a new generation of learners – children and

teenagers – who are growing up and experiencing the advances of information and communication technologies" (2002, p 28-29. Free translation).

A Brazilian Law (Lei de Diretrizes e Bases da Educação Nacional - LDB), from 1996, praises the importance of focusing on "digital literacy" at all levels of schooling, from elementary school to college. In that sense, the use of the Internet enables the arousal of social practices and situations for literacy through communication tools available.

So, from the considerations pointed out here, how can literacy practices be understood in the context of the introduction of laptop computers in the classrooms? Which abilities may be related to literate practices as we understand this concept? Which actions and conducts that were observed may be related to literate practices?

INITIAL STAGE: INTRODUCING LAPTOP COMPUTERS IN A PUBLIC SCHOOL

With the previous considerations in mind, this paper is aimed at the analysis of the context of laptop computers being introduced in a public school focusing on practices showing digital literacy of students and teachers involved. The study is outlined as a qualitative exploratory research (Richardson, 1999). Data were collected within a larger scenario, which is a research project that is aimed at the study of digital technologies in education investigating school cultures and the appropriation of innovative ways of teaching and learning. The school is located in a beach of a small town that is 165km away from the capital of the state of Rio Grande do Sul, Brazil. During the off season, population is not more than 8 thousand inhabitants. There are 209 students in the school, ranging from pre-school to the final grades of elementary school and including the especial program for Youth and Adult Education (Educação de Jovens e Adultos - EJA), which takes place in the evening shift for young adults who are already placed in the work market. The school counts on a staff of 24 teachers.

Students attending this school come from different suburbs and villages in town, and are mostly from low-middle income families. Most did not have a computer before. Some report using computers occasionally at the telecentre available in the region. Before joining the 1:1 project, the school only had 3 computers, located in the library, and counting on a very unstable access to the Internet via radio.

As it joins in the UCA Project, the school is enrolled in a qualification program determined by the Brazilian Ministry of Education and which has been coordinated by the Laboratory of Cognitive Studies of the Federal University of Rio Grande do Sul (UFRGS) and the support of the University of Caxias do Sul (UCS). Teachers, school managers and other school staff members are participating in the program.

The corpus for analysis in this study is comprised of video recordings from the first interactions with the educational laptops by students, teachers and employees of the school. The corpus was built from the transcripts of the videos made in the school 3 months after the laptops had been distributed and teachers had already started their qualification program. Recordings were made in every classroom during the 3 shifts of the school's working hours. An average 30-minute period was spent in each classroom with the video recording and observation. Data transcription was carried out following a sharp observation of the videos, whose second step was the transcription of dialogues, with special attention given to expressions and actions, and the third step was checking transcripts while watching the video recordings.

A FIRST ANALYSIS

From an initial organization of the data, which was based on thorough reading of the transcripts resulted the categories and subcategories defined upon theoretical approach chosen for this analysis and displayed in Chart 1.

Observations and video recordings of the classrooms where laptops were being used showed that most activities were focused on using the Internet. The transcriptions that were analyzed show that Internet use was mostly for the exploration of search engines as a complementary activity of studies being carried out in the classroom, and that were focused on teacher's lectures, explanations and definitions. In general, students were guided by the teacher in their search on the Internet and told to write down their findings in writing using paper and pen. Searches ranged from complementing contents of the subjects studied in class to support materials for learning projects that were being carried out.

The data analyzed showed that teachers and students from the 4th grade on – students aged 9-10 – are fluent users of search engines when looking for specific information, using keywords, searching for images and texts, commenting their findings with their classmates and teachers. Younger children – from pre-school groups to the 3rd grade were not using the Internet to search information and for that reason we cannot infer anything about its influence. Activities with these groups were centered on educational games, introduction to email messaging, and using text editors, which can also be considered evidence towards digital literacy.

Chart 1

Categories	Subcategories
Searching the Web	Learning how to use search engines.
	Reading and attributing meaning.
	Transposing information to individual's reality.
	Producing new texts.
Communicating	Using email, social networks, etc upon demand – Learning how to use resources available.
	Interacting spontaneously. Adopting, adapting and appropriation of different resources.
	Inviting others for communication purposes (email messages and social networks).
	Innovating their forms of communicating by integrating different digital technologies.
Publishing	Learning about technical resources and copying and pasting ideas, texts, images, and videos from other contexts. Publishing upon demand and in specific contexts (school, community, and classroom).
	Appropriation for publishing tools, exploring possibilities, expressing personal opinions and publishing in external publications.
	Creating and producing (texts, videos, images), integrating media, building possibilities in authorship. Increasing options for publication.
	Ethical and responsible authorship to publish their opinion, placing themselves as the other as a reader and polyphonic author.

Attributing meaning to search actions and criticism towards their findings were observed in very few groups. Only students being guided by their teachers showed this. On the other hand, these subcategories were observed a few times on teachers attending the qualification program. During these meetings, there was some evidence of teachers transposing the information they found to their reality, in addition to creating and inventing new productions for their online publications (blogs, portfolios, etc).

Only in two classrooms were we able to observe students discussing, reflecting, problematizing and reconstructing what was found in their searches, what would characterize transposing information to reality and producing new texts from the search. In these two groups, other kinds of support material was available in addition to the laptops, such as books, notebooks, magazines, and encyclopedias were being used by the students to confront with the information they found online. The transcription of teachers' statements in these groups shows their concern with having students criticizing and analyzing their searches on the Internet and constantly problematizing what they took for granted. The purpose was to transpose information to their reality. In these classrooms, we could observe that other resources from the laptop were being used simultaneously with the Internet search, such as image and text editors.

It is possible to notice some distance between the actions and meanings that arose during the qualification and how they were transformed into teaching practices. That distance can be understood at the light of the biology of knowledge (Maturana, 2002). This theoretical framework emphasizes changes in conduct result from learning that follows structural transformations, which are produced from convivence and the coordination of actions. One can think that this is the way how the use of laptops based on practices aiming at digital literacy will result in effective changes on teaching-learning practices. When that does not happen, we can understand that structures have not yet been changed, and what one has are intentions and verbalizations signaling possibilities of changing. That means no matter how the context can instigate, disturb, and make things possible, what will really happen to the teachers depends on their structure and that structure only can determine changes, which can be observable in their interaction with their peers and in their teaching practice as well. Writing – in the context of digital literacy – becomes an important communicative possibility. And with the resources available for online communication, such as email, social networks, instant messengers, etc., writing becomes real authentic communication, rich in meaning (Valentini, 1996). Communicative exchanges on the web can be a way of promoting cooperation and confront among students, and of building a social practice with enough conditions to favor the learning process.

From the data analyzed in the recordings of students practices(from 1st to 3rd grades – ages 6 to 8 years old), we could see that they were learning how to use email messages, to create their email addresses, to send and reply messages, still guided by their teachers. Students from the 3rd grade were also using the text editor to write their production (stories and poetry) that would later be presented to the other groups of students in other grades. It is possible to identify here some transformation of the communicative social practice evident

from the innovation in their ways of communicating in writing, using a text editor, integrated with different digital resources and with an audience in mind.

Another observation concerning communication was possible in a polyphonic movement on which some students (5th to 8th graders – 11 to 16 years old) were engaged while using the instant messaging tool available in the laptops. Many were using the instant messenger (IM) to interact with students in their classrooms or in other rooms. This alternative for communicating was an initiative taken by the students – whereas many teachers do not know how to use that tool, and data indicate that some teachers were not even aware of that communication going on between the students. Several students claimed that they used the IM and listened to music simultaneously to the activity that had been assigned by the teacher. These simultaneous and independent activities – whether teachers knew they were taking place or not – offer evidence of how the generation described by Prensky (2001) acts and thinks. This generation, described by the author as the digital generation, is used to dealing with technology naturally and carrying out several activities at the same time. They are multitaskers and in front of the computer, or in the case of our study, in front of the laptops in their classroom, they bring up the need of reorganizing the classrooms. And that reorganization does not refer to physical configuration only, but also to its pedagogical dynamics, that has to be different from lecture-based lessons.

And even though the data analyzed in this study refer to an initial stage of the introduction of laptops in the classrooms, we were able to identify several movements related to the category "publishing", which was evident in different moments and with different groups. We were also able to observe a movement towards copying and pasting texts and images into students' productions, and in many cases these assignments were published upon teachers' demands for students to do so. We have also found some evidence towards communication and written production in our observation of the teachers and staff members of the school. In the transcriptions of the video recordings, there are statements by the students indicating that they publish their personal opinions in blogs built with their teachers where they discuss matters that interest both students and their community.

In fact, blogs seem to be a common practice for communication and publishing within the school and not only for individual groups, and their use is not limited to subjects that have been discussed and studied in their classrooms. For example, the blog registered as "My favorite writers" (Meus escritores favoritos) was built in order to publish and comment texts and poems written by students, teachers, school staff and other members of the community. In these blogs, we can find posts made by students and teachers, pictures, posters, poems, photos registering activities carried out by the school. Most posts have been commented by teachers and students, indicating there is a polyphonic movement being built and the possibility of transforming communicative and social practices.

CONCLUSION

In the analysis of the initial stage of the introduction of laptop computers in a Brazilian public school we were able to identify some evidence of practices related to digital literacy. It is important to point out that students received the laptops to use in their classrooms less than 3 months before the data for this study were collected and that most of those students did not have systematic access to IT and the resources made available thanks to the laptops. Mobilizing and engaging teachers and school managers – as well as offering continuous education and qualification programs – is extremely important to build new possibilities for the teaching practices and redimensioning current practices.

It is important to emphasize that changes and innovations should be founded on a vision of learning based on interaction and cooperation aiming at the construction of knowledge. Otherwise, the presence of laptops will only be some kind of instrumentation and not an opportunity of changing and redimensioning educational practices and school culture. In this scenario, teachers need to function as mediators and guides, much more than instructors or lecturers.

It seems to us that – when introducing laptop computers – it is necessary to take into consideration strategies and interventions that can enable insertion to become digital inclusion. That means "forming people digitally literate, with competences to solve everyday and professional life situations and to face the challenges from their insertion in the information society" (Almeida, 2005, p.173. Free translation). The single presence of laptops or any other technological device does not assure per se any improvement in quality in education. To achieve that, it is necessary that teachers, students, school and society together engage on processes aiming the transformation of educational and social practices, in order to characterize digital inclusion, providing the exercise of citizenship, authorship, and critical and autonomous participation of the learning individuals in the world.

From these considerations, we can say that digital inclusion as a consequence of practices aiming at digital literacy may result from convivence, starting from a common goal: to discuss and reflect on teaching practices, on the possibilities that arise from the resources available on the laptops, and to rethink educational processes, supported by flows of interaction and cooperation. The way how this flow organizes itself is given by recurring actions by teachers and students, besides the school managers, who – together – are renewed and transformed. This flow is the source of energy that by circulating in the interactions can generate and regenerate the system itself through ideas and questions that arise. Therefore, we can infer that digital inclusion will take place from this communication flow running between the participants, feeding them and being fed by them, and the dynamics that emerges from that flow supports the process of convivence.

315 - Laptops for Students: Strength and Weakness of the Portuguese Initiatives

Ana Amélia Amorim Carvalho

Department of Curriculum Studies and Educational Technology, Institute of Education, University of Minho, Portugal
aac@ie.uminho.pt

Abstract: This paper focuses on the Portuguese initiatives to offer laptops with Internet connection to students at a reduced price. Five initiatives were launched: "Schools, teachers and laptops"(2005-2006), "e-school" (e-escola) (2007-2008), "e-little school" (e-escolinha) with Magellan (2008-2009), "Learning and Innovating with ICT" (2010-2013), and this year "e-school 2.0" (e.escola 2.0). These initiatives are briefly described and criticized with regards to its strengths and weaknesses as well as teachers' ICT competencies to integrate laptops in the classroom.

Keywords: Laptops, Initiatives, ICT, Teachers training

INTRODUCTION

Several countries adopted the initiative One Laptop per Child launched in United States of America and reported their effects on teaching and learning such as in the United Kingdom (BECTA, 2004) or in New Zeland (Cowie et al., 2008).

In Portugal, five initiatives characterize this laptop adoption process by teachers and students from the academic year of 2005-2006 to 2010-2011, namely: "Schools, teachers and laptops", "e-school" (e-escola), "e-little school" (e-escolinha) with Magellan, "Learning and Innovating with ICT", and "e-school 2.0". All these initiatives will be described and the data will be reported. This paper also focuses on teachers' ICT competencies and training in order to integrate laptops in the classrooms.

Schools, teachers and laptops initiative

The initiative "Schools, teachers and laptops" was launched in 2005-2006. This allowed schools to apply for 24 laptops, a multimedia projector and one wireless access point. Of those 24 laptops, 10 were for teachers to use individually and professionally and the remaining 14 were to be used by the teacher with his/her students in the classroom. Access to the initiative was made through an open call which was an innovative and important method for engaging teachers and schools in the use of ICT. Most schools (95%) from the second and the third cycle of primary and secondary applied for it.

The duration of school projects could take one, two or three years, namely 2006-2007, 2007-2008 and 2008-2009. The public announcement call included the regulations under which the proposals were accepted and evaluated. It includes the use of computers, networks and the Internet by students and teachers; the production of class materials using laptops; visible evidence of the contribution made towards school teachers´ professional development; use of the computer as a school management instrument; and the availability of information regarding project development on the Internet.

Each project proposal had to define: goals to be achieved, activities to be developed in addition to its chronogram; number of laptops necessary, the name of teachers enrolled in the project; professional competencies to be developed; teachers´ training needs and support; indication of the departments and courses involved; students to become involved, outcome indicators, and project evaluation criteria.

The project activities should also include the policy for equipment use as well as their assignment to teachers and students.

Table 1: Number of schools participating in the Initiative and number of laptops

Region of Portugal	Number of schools		Number of laptops
	f	%	
North	401	34	9,585
Center	252	22	5,949
Lisbon	351	30	8,396
Alentejo	95	8	2,243
Algarve	65	6	1,538
Total	1,164	-	27,711

The number of laptops distributed in 1,164 schools was 27,711 (table 1). This initiative was very well accepted by schools being as 95% of them applied to it.

A study regarding this initiative was conducted by Ramos et al. (2009) which included quantitative data concerning the initiative's impact on schools, teachers and students. Two questionnaires were developed to collect data from schools and teachers. The study also included qualitative data collected using an ethnographic study which aimed to analyze and comprehend the impact of the initiative and understand the innovative approaches in class. Ten schools were analyzed as case studies, including 50 statements from teachers and 100 student interviews.

Data presented in this paper regarding this initiative is based on Ramos et al. (2009) report.

INITIATIVE'S IMPACT ON THE SCHOOL, TEACHERS AND STUDENTS

The population of this study includes the schools and teachers enrolled in the Initiative. The questionnaire was completed by 736 schools (63%), the school executive board, and by 4,666 teachers (33%).

Table 2: Age and gender of the respondents teachers (n=4,666)

Items	Variables	f	%
Age	<25 years	15	0.3
	25-34	559	12.0
	35-44	2,165	46.5
	45-54	1,548	33.3
	>54	367	7.9
	Did not reply	12	-
Gender	Female	2,995	64.5
	Male	1,652	35.5
	Did not reply	19	-

In what concerns the teachers´ age, 46,5% range between 35-44 years of age and 33.3% between 45-54 (table 2). The majority of respondents were females (64.5%). More than half of the respondents (52%) possessed 10 to 19 years of teaching experience, 21% 20 to 29, 17.7% 0 to 9, 9.1% 30 to 39, and 0.1% 40 to 49.

Most respondents were Mathematics, Biology and Geology, Physics and Chemistry, Portuguese and Computational Science teachers.

The schools´ administrators considered that the initiative results were positive in what concerns student involvement, previous outcomes and results achieved. The less successful one was teacher training. However, the project contributed to professional development through the possible training, self-learning, and peer learning. The laptops were mostly used in teaching classes followed by the production of pedagogical materials. Laptops were also used for team work as well as for working with students in educational projects. They were less used in school management.

The Centers of Competencies to support the use of computers and Internet in schools (CRIE), disseminated in the country supported educational activities in schools. Each Center had to collect data regarding the project development. The Center staff had meetings with the teachers in each school and later reported the situation.

From 1,212 schools from the 2nd and 3rd cycle of primary and secondary school, 1,164 involved themselves in this initiative (table 3). Each laptop was used by an average of 3.5% of teachers and 20.5% of students (Ramos et al., 2009).

The study allowed the identification of the major difficulties experienced during this process in schools. One of the major constraints is related to the number of laptops per school; followed by technical difficulties with laptops and Internet access; the organization and management of rooms and timetables for teachers and students; the articulation and interaction between teachers, and the lack of teacher training in the educational use of laptops and ICT. It is also important to note that some schools waited long for the equipment to be delivered. The worst situation was the lack of teacher training in ICT.

Table 3: Main indicators of the Initiative (Ramos et al., 2009, p. 31)

Entity	Indicators	f
Schools	Number of schools (2nd and 3rd cycle and secondary)	2,112
	Number of schools applying to the Initiative	1,181
	Number of school projects approved	1,164
	Number of school projects not approved	48
	Number of schools participating in the evaluation	736
Teachers	Number of teachers involved in the school project	13,968
	Number of teachers participating in the evaluation	4,666
	Number of teachers that used the laptops	40,591
Students	Number of students that used the laptops	333,086
Laptops	Number of laptops	27,711
	Maximum number of laptops per school	48
	Minimum of laptops per school	14

The initiative did not contemplate teacher training. Teacher training had to be carried out by the school. This option was not well succeeded. Many schools had difficulties in providing appropriate training.

The advantages of the initiative, according to Ramos et al. (2009), are related to the portability of the technical equipment, teacher motivation and the students using laptops, better access to the equipment, and an ICT modification in teaching. The students were more interested in learning and showed more interest in the activities developed using a laptop.

The school laptop project involved teachers, school administration and an effective participation of the school community. Each school and its participants get involved in a shared project supported by all members.

The impact of the initiative on the school dynamic is related to the augment of laptop use in the classroom. In most schools, laptops were used in different classrooms taking advantage of its portability however, in some schools laptops were always in a specific room such as a computer lab.

Table 4: Use of laptops in the classroom (n=4,666)

Use of laptops in the classroom	f	%
Did not use	65	1.4
Once or twice per term	686	14.8
Once or twice per month	1,259	27.1
Once or twice per week	1,992	42.9
Every day	637	13.7
Did not answered	27	-

The teachers indicated that 1.4% did not use laptops in the classroom, 14.8% used it once or twice during each term, 27.1% used it once or twice per month, 42.9% used once or twice per week and 13.7% used the laptops daily (table 4). These percentages prove the effort put forth by teachers in order to integrate the laptop in their classrooms.

The laptops in the classroom were used to present content (58%), searching information online (50%), group work (50%), project work (48%), solving exercises or problems (39%). The impact of the initiative on teachers and teaching is related to the diversity of pedagogical strategies, the production of materials and resources, and a facilitated access to ICT for teachers and students.

Ramos et al. (2009) identified that teachers required technical and pedagogical training in accordance with the goals of each project. The need for technical support as well as school equipment and laptop maintenance was also identified.

e-school (e-escola) Initiative
The initiative "e-school" (e-escola) was launched in 2007-2008 and offered laptops with Internet access (Mobile broad band) to 10th grade students, teachers and students of New Opportunities (Novas Oportunidades) programs at a reduced price. In 2008-2009, this initiative was expanded to students from the 5th grade to the 12th grade. The price depended on the student's family income. If it was low or too low, they would receive a free laptop and pay a small amount for the Internet connection (table 5).

Table 5: Acquisition of laptops and Internet connection

School Social Support	e-School levels	Acquisition
A	Level 1	Free laptop. Internet connection 5€
B	Level 1	Free laptop. Internet connection 5€
C	Level 2	Free laptop. Internet connection 15€
Students with no SSS	Level 3	Laptop 150€. Internet connection with 5€ discount to regular prices.

e-little school (e-escolinha) Initiative

The initiative "e-little school" (e-escolinha) was launched in 2008-2009. The netbook Magellan is for primary students only. The netbook is free for students with a very low family income. The Internet connection was not mandatory.

The Magellan includes some educational software (GCompris). It contains Windows XP and Linux.

A survey was conducted to primary school teachers from May to July 2010. 9,473 teachers completed the questionnaire online (GEPE, 2010). Most teachers (74%) considered the initiative good (55%) or very good (19%).

More than half of the teachers considered that the laptop stimulates creativity in students (68%), augments students´ interest in learning (59%), and stimulates teacher work (53%), table 6. The respondent teachers are divided when it comes to the Magellan effects on learning: improving (50%) or not learning results. Less than half of the respondents (49%) indicated that the laptop is an indispensable learning tool. All of them, except 14%, considered that Magellan is useful for other things rather than playing games only.

Table 6: Use of Magellan

Magellan…	Disagree	Not agree nor disagree	Agree
Stimulates creativity in the child	13	19	68
Augments the child interest in learning	20	21	59
Stimulates the teacher work	21	26	53
Improves learning results	19	31	50
Is an indispensable tool for learning	28	23	49
Is useful for playing games only	73	13	14

Most teachers (92%) referred that they use the Magellan in the classroom. Most used activities that would teach the child how to use the laptop (93%), access the Internet (79%), browsing and searching the Web (78%), reading (71%), doing content presentations (64%), listening to music or watching videos (60%), and accessing the digital library (59%). With less use, we have drawing (47%), playing games (40%), sending messages (29%), and supporting homework correction (23%).

Teachers use the laptop to teach Portuguese (95%), Environmental Studies (90%), Mathematics (67%) and Arts or Physical education (37%).

Table 7: Use of Magellan per discipline

Disciplines	%
Portuguese	95
Mathematics	67
Environment Studies	90
Arts or Physical education	37

In terms of the frequency of use in the classroom, the highest percentage is 49% indicating once per week (table 8).

They were also asked if they use the resources available in the School Portal to prepare their classes: 33% did and 65% did not.

Although most of the respondent teachers are using Magellan in the classroom, the daily frequency of use is still very low (8%). One possible explanation is the lack of training in using Magellan and ICT in the classroom.

Table 8: Frequency of Magellan use in the classroom activities

Frequency of Magellan use in the classroom activities	%
Everyday	8
Four days per week	4
Three days per week	14
Two days per week	24
One day per week	49
Did not reply	2

Learning and Innovating with the ICT Initiative

The initiative "Learning and Innovating with ICT" (Aprender e Inovar com TIC), 2010-2013, promotes the educational use of ICT in order to improve students' learning. The schools were invited to submit a project until the 15th of December 2010. The idea of an open call was used again, as was done in the initiative "Schools, Computers and Internet". It intended to motivate teachers to submit a project that used the laptops. The open call announcement privileges the 1st Cycle of primary school, the use of Learning Management Systems, and the production and sharing of digital educational resources.

One hundred schools were selected. The approved projects will be carried out until the end of the academic year of 2012-2013.

e-school 2.0 Initiative

On the 8th of February 2011, the initiative e-school 2.0 (e.escola 2.0) was launched. It follows the initiative e-school, maintaining the offer of laptops and Internet access, with no cost to the State. It intends to promote the creation and usage of educational contents, and intends to motivate the use of the next generation networks (NGN).

Teachers' ICT Competencies and Training

The initiative e-teacher (e-Professor) was launched in 2007-2008, allowing teachers to buy laptops and Internet connection at reduced prices. The initiative affected kindergarten educators and teachers from primary and secondary schools.

Until 2005, some ICT training courses were available in Teachers Training Centers, but they were not mandatory. Teachers could choose ICT courses or other subjects.

In 2006-2007, teachers received training regarding the Learning Management Systems Moodle. This training was demanded by the Ministry of Education and was mandatory for teachers.

In 2009[ii], a plan for training teachers in ICT Competencies was developed and is being implemented in Teachers Training Centers (table 9). Three levels of teachers ICT competencies were identified (table 9), and level 1 and 2 are compulsory to all teachers.

Table 9: Levels of ICT competencies for teachers

ICT Competencies	Description
Level 1 – Digital Competencies	Access and use of digital information. Writing digitally. Safe Internet. -Editing digital pictures and organizing register data in spreadsheets; -or organizing register data in spreadsheets and data bases organization and creation; -or synchronous and asynchronous communication online. Creation of presentations.
Level 2 – ICT Pedagogical and Professional Competencies	Two mandatory trainings: -Teaching and learning with ICT (applied to the disciplines the teachers teach) -Assessment of learning with TIC. Two optional trainings: - Multimedia interactive whiteboards Or -LMS. -School library, literacies and curriculum. - ICT Special Needs. - Digital educational resources: production and assessment. -Educational e-portfolio -Leadership and technological modernization of the schools. -Coordination of ICT projects.
Level 3 – ICT Advanced Competencies	Master and PhD Programs in Higher Education.

In 2010, almost all teachers received training in multimedia interactive whiteboards. The training for each course of level 1 or 2 takes 15 hours.

CONCLUSION

The objective of having teachers and students using laptops was achieved. The initiatives were important in motivating teachers and students to use laptops in the classroom, to access the Internet and collaborate with others. Nowadays, in Portugal, 98% of students aged 9 to 16 years have internet access.

There has been an effort to offer teachers ICT training. . Firstly, ICT training was optional mainly during the nineties and before 2005. In 2009, a plan for training teachers in ICT Competencies was developed and is being implemented. However, the number of hours per session (15h) is insufficient for teachers to feel comfortable with ICT.

Students from the 2nd cycle of primary school to secondary school could buy a laptop with Internet connection at a reasonable price. However, most of them do not bring their laptop to the school because it is heavy (3kg), as was reported in the studies of Moura & Carvalho (2008) and Certal & Carvalho (2011). The Magellan is lighter (1,4kg) but teachers do not use it daily. More specific ICT training is necessary.

We may conclude that many things change the way some teachers teach nowadays. However, we must enhance the number of teachers using ICT in an educational context. More training and pedagogical support is necessary.

315 - Citizen Digital Emancipation and 1 to 1 Model: New Cognitive Regimes for the Use of Laptops in Schools?

Daniel Lopes[1] and Eliane Schlemmer[2]

Graduate Program in Education PPGEDU, UNISINOS University, São Leopoldo, Brazil
[1]danielql@unisinos.br, [2]elianes@unisinos.br

Abstract: Over the past twenty years the use of digital technologies (DT) in schools has been ruled, among other factors, the maintenance of cognitive pre-established cognitive regimes. These regimes have been characterized mainly by the hierarchy and homogeneity of the actions and interactions, in addition to the institutional control over the times and spaces of learning. This model has been challenged by new cognitive regimes sustained by the digital culture idea, guided by heterarchy and heterogeneity of authors and modes of authority. The modality 1 to 1 brings new challenges and questions about the established cognitive regimes. How the idea of citizen digital emancipation could help in the review of these established cognitive regimes? This article aims to present this discussion based on early evidence and thoughts on a public school that is part of governmental Program One Computer per Student in south of Brazil.

Keywords: digital emancipation, citizenship, laptops on education, primary schools

INTRODUCTION

The technological development of the current era has been producing new possibilities of expression of the subject, therefore, new possibilities for its inscription in the world, its socialization. From the hand written book, going by the printed paper and for the diversification of the formats of the book, until the coming of the digital technologies as the Web and the handhelds (portable), the individual has been finding many and diversified forms of enrolling in the society. Communities in the internet, social nets of relationship, blogs, Twitter, fan fictions, virtual digital worlds in three dimensions (MDV3D), among other, they offer new possibilities for the individual to manifest feelings and ideas, be through text or of audiovisual images and, in the case of MDV3D, besides the text, the voice, the gestures and the graphic representations in 3D. When they break up with the visible borders of the bindings and printed papers and they allow new compositions, cuttings and transmission online, the digital publications and the electronic books indicate "a revolution in the structures of the material support of the writing as well as in the ways to read" (Chartier, 1999, p. 13). On the other hand, the author emphasizes that this revolution also concerns the production manners and reproduction of the texts, as the digital technologies make possible that a same person could be author, publisher and dealer at the same time, simultaneous. The technology that offers support these new reading and writing forms appears as new possibility of inscription of the individual, when, enrolling themselves in the virtual spaces, he recognized himself and he is recognized for others. In that sense, the digital culture indicates a radical transformation in the production devices and of spreading of the knowledge, pointed for some authors as essentially democratic, in the way that it potentiates new authorities facing the scientific productions, informative and cultural (Lévy, 1999, 2004; Castells, 2005; Lemos, 2002, 2009).

In fact, the digital technologies have been making possible new socio-cultural manifestation forms of several orders, from social movements to public and private entities, as well as they have reconfigured and created new forms of collective organization. But who has been inhabited those virtual spaces? How is the socialization of the individuals facing the new reality?

As these sophisticated and complex technologies increase manners of being and of inhabiting the contemporaneity, conditioning almost everything to the informational pathways, at the same time, it also creates an exclusion pathway in relation to the knowledge, to the culture and to the work, since the technological apparatuses that give access to the digital means many times have an inaccessible cost for the social layers less favored economically. In order to minimize the social impacts of that phenomenon, it is possible to observe in Brazil several actions of the civil society, ONGs and of the own government designated under the *digital inclusion* term. In Brazil we can still highlight, inside of the national politics of *digital inclusion*, the Broadband in Schools Program, that has been making available the fast access to the internet in Brazilian public schools, besides offering qualification courses in the pedagogic use of TD to the

teachers of the participant schools with support of the Nuclei State and Local Technology in Education (NTE and NTM).

These politics and inclusive actions seek mainly to make possible the access the some digital resources, mainly to the internet. However, the reflection on the exclusion pathway in relation to the digital culture can not be limited to the economical subjects, to the subject of the material access to the technological apparatuses that make possible the access to the digital world. It is necessary to take in consideration the analysis of the new cognitive regimes that are produced in interaction with the digital technologies, mainly in the school spaces, as those spaces start to exercise primordial role in the public politics of digital inclusion. In that sense, the problem of making part of a digital culture that enters in the line of the attributions of the school brings to the surface a double process: technician and symbolic. Being like this, the discussion that involves the digital technologies demands taking into account as much the technique as the culture.

COGNITIVE ECOLOGIES

Lévy (2004), when analyzing the technological development and the culture, proposes that the ways of thinking are deeply molded by material devices and sociotechnical collective. With the term *cognitive ecology* Lévy defends "the idea of a thinking collective human beings-things, dynamic collective populated by active singularities and mutant subjectivities" (p. 11). In the same sense, he introduces the idea that the society can be considered as a great hypertext or a wide cognitive net, mobile, of several formats and ways, where individuals participate connected to a common net, but that, however, they just possess a partial and deformed vision for countless translations and interpretations. For the author, these individuals compose what would be local machines, singular, subjective, each moment injecting movement in what would be the great social hypertext: the culture. The author adds that the state of the techniques influences directly on the topology of this wide cognitive net, on the relationship types in its executed, about the association manners, the transformation speeds and circulation of the representations, always in a constant metamorphosis.

Such analysis is clearer when Lévy establishes an analogy between the model of the thermodynamics, analyzed by Michel Serres, and the computational model. In the same way that the creation of the steam machine provided the elaboration of a measure of power (Horse Power) - defined by a relation between time and space - Lévy tries to show that the computer became today one of these technical devices for which we noticed the world. It is not just in an empiric plan (as in the calculations of astronomical distances), but also in a transcendental plan. He affirms that more and more we conceived the society, the alive beings, or the cognitive processes through a matrix of computational reading. In the same way as the telegraph and the telephone served to think the communication in general, he affirms that the experience can be structured by the computer. Like this, the products of the modern technique are important sources of imaginary, entities that participate fully of the institution of noticed worlds.

The Lévy's idea about the existence of a symbolic hypertextual net understood from the concept of cognitive ecology, it finds in the digital technologies new possibilities of collective agency of socialization. For so much, it is necessary to define as that discussion can help to think the constitution of several social nets (of learning, of work, of leisure, of art and culture, etc.). As a necessary way, Maraschin (2000) defines the socialization "in the sense of the inclusion, of the active belonging, propositional in the social/cognitive nets; assumption of a subjective position of authorship inside of the predominant cognitive ecology" (p. 55). The author detaches that, differently of the usual understanding that there is about the studies of the cognition in relation to the human development, the cognitive ecology places the discussion in the field of the social psychology, in the collective ways of producing knowledge and of socializing. At the same time in that this perspective enlarges the focus of the individuals' analyses for the collectivities, Maraschin proposes that the object of a cognitive ecology is thought from the cognitive activity as "(...) invention-construction subjective-objective and not as a representation of something given out, in the exteriorities. The cognitive ecology constitutes a space of agencies, of interactive lines, of constituent relationships, in which are define and redefine the individual, institutional and technical cognitive possibilities. It is in that space of agencies that are conserved or generated modalities of knowing, the forms of thinking, the technologies and the institutional manners of access and of knowledge acquisition" (p. 56). The author complements this idea affirming that a predominant cognitive ecology allows "(...) the consolidation and emergency of 'cognitive regimes' constituted by the groups of rules created through processes of learning, through concrete practices involving the coupling with cognitive technologies" (p. 56).

STRUCTURAL COUPLING AND THE DIGITAL TECHNOLOGIES

In the extent of the discussion related with the digital technologies, Maraschin (2000) does an analysis proposing that be thought the hardware aspects (physical structures, biological or technological) in a way

integrated into the software (logical/symbolic structure), proposing that the physical structure constrains the symbolic structure, while this can establish new meanings and logics that echo in those (transformation of the structures). In the case of a cognitive ecology of regime predominantly oral, for instance, the informational way is determined by the own biological structure (apparatus vocal, hearing, neurological, etc.) that any healthy individual disposes. However, the conceptual/symbolic structure is a product of the socio-historical and collective processes; whose interactions and couplings have been allowing the production of shared and diversified senses. Everybody that share of the oral regime is capable to do part of that socio-cultural net, and to socialize as they participate actively of that ecology. Historically, the individual's inclusion in that regime has been happening spontaneously, without a formal institutional process. However, it is not possible to think this process of spontaneous inclusion as a simple process, because that cognitive ecology of oral regime is not structured in a homogeneous way. It still may be consider other regimes that interfere in this ecology, as the different regimes of power, the politics, the knowing, among others. Depending on the context can be certain *orally type* accepted that determines the inclusion or not of the individual.

In the case of a regime ecology predominantly writing, it is added to the biological-symbolic coupling of the oral regime, the coupling of technological tools (boards, parchments, books, feathers, pen, and machines). This coupling, at the same time in that it enlarges the reflection/formalization possibilities and it materializes the support of the ideas through the inscription, it brings new meaning to the speeches as it distances the statement from the context of their speakers, giving new meaning to the space and time categories present in the speeches of the orally regimes. It appears, like this, new forms of collective agencies, constituents of new social nets and, at the same time, of new inclusion and exclusion regimes.

With the appearance of the digital technologies and the emergency of a digital culture, it can be affirmed that it is in process the appearance of a digital cognitive ecology, what turns fundamental to study the socio-cultural agencies in course, as well as the inclusion and exclusion processes in the social nets that are formed. In this context, the school, while space of the individuals' socialization, surged as an important agency of these processes, because it is inserted in the projects of life from the childhood and from the youth.

COGNITIVE REGIMES, SCHOOL AND COMPUTERS

In spite of the education do part of the life and of the socialization process in the childhood and in the youth, the meanings attributed to the school not always are positive. For some, to be at the school can be an imposition; a violence which that should be resisted or abandoned (Sirino; Cunha, 2002); for others, the school can be a fundamental support in the construction of the life course (Abrantes, 2003).

The social question in Brazil has been marked historically by the social, economical, cultural, moral and symbolic inequalities (Arcoverde, 2006). Along the years, it is evidenced a process of accentuation of the accumulation of the wealth and the consequent increase in the inequality of income, fruit of models of development "slave, industrial - developmental, fordist - taylorist and of flexible reorganization" (p. 3). In this context, the image that it is tanking from the school was always nurtured by the promise of reducing such inequalities, mainly from the idea that the education would be capable to promote the individual's emancipation and his/her productive insert in the society and in the culture. In spite of that, what in fact is observed in relation to the schools is the reproduction of exclusion models, fruit of education processes that produce the failure and the abandonment of the studies. And what would be the predominant cognitive regimes at school?

The classroom traditionally has been organized in a way that the time and the space of the activities accomplish pre-established itineraries. The organization by series or stages and the curricular grade or disciplines can be considered as macrostructures of the school. These macrostructures have been conditioning the planning of the activities in classroom, defining what and when certain curricular contents should be approached. In general, that planning guided by the clock and by the curriculum concerns the execution of teaching stages and of evaluation systems that intend to designate or to indicate if the student is or not developing. In order to attest this development, the tests and the written works, applied according to a schedule, have been the main instruments of registration of the productions and of the evaluations, and they can be pointed as an important part of the microstructures of the school. All that organization of the school reveals a cognitive regime mainly of written order and conditioned to the inscription in spaces and predetermined and authorized times. The measure of the success or of the failure happens, largely, in the adaptation or not of the individuals to this regime, as the individual is capable to produce in the time that is allowed to him/her. The learning and the individual's development, under this regime, are understood not as an event, but as a product of the proportionate engenderment by these regimes. The planning of the activities in the classroom follows the defined times, in first instance, by the macrostructure of the school calendar,

that at the same time in that it engenders a way of learning with marked date, it produces the school failure and, consequently, the losers.

In this context, the idea of having computers in the education was nurtured, in part, by the conviction that the technology would transform the school, promoting the overcoming of the problems related to the learning and, consequently, it would reduce the disapproval indexes. In that case, the failure idea as an inaptness of the individual justifies an entire support system and pedagogic reinforcement that it checks to the technologies a prosthetic image, capable of re-conducting the apprentice the condition of more capable.

What is noticed along the last twenty years is that the computer has been introduced in the schools in a way not to interfere in the instituted regimes, and, except for the specific technical courses, what is produced when using the computer, that is, enrolled with the digital support, it is little taken into account, besides not constituting as instrument of evaluation of the development and of the learning.

Under the justification of assisting all of the students' groups and teachers, the computers are gathered usually in rooms or laboratories, becoming almost autonomous units in relation to the remaining of the school, a foreign place to be frequented or avoided. More recently, approximately in the last ten years, the popularization of the personal computers and the appearance of the Internet have been producing new meanings in relation to the computer in the school, and the computer labs, consequently, have been acquiring new status. But the increase of the demand and frequency of using of the computer labs has not been provoking substantial changes in the instituted cognitive regimes. On the contrary, the computer labs are the ones which fix themselves to the established and certain regimes by the macrostructure of the schools.

In the case of the shared use of the computer labs, in some schools the time in an equal way is distributed for all of the groups (for instance: 1h or 2h a week), usually following the orientation of opportunity of using of the technological resources to all the students, avoiding a supposed privilege or monopoly of using on the part of some teachers and groups. At the same time, this is a form of justifying the financial investments, be public or private, for the school community. This regime of shared using of the time is usually defined in a shared way (with the teachers' participation) or by the pedagogic coordination of the teaching institutions. In other cases the shared use of the computer labs follows the same rules of using of the other laboratories for area (for instance: physics or chemistry laboratories), being to the teachers' criterion determine the frequency with they use the resources offered by the laboratories, usually through the previous scheduling. In that regime of time, it is to the teacher's criterion when and how to use the technological resources, usually in function of the topic or the content approached in the classroom. In spite of that, it is common find teachers' reports affirming that to use the space of the computer labs is wasting of time, be for the absence of appropriate software, be for the ignorance of the pedagogic application of the existent resources, or be for the insufficient time that they dispose because of the schedule of their disciplines. It is also common find reports that the space of the computer science laboratory is used as pastime, a form of rewarding the students for activities or stages accomplished through digital games or access to social nets. In that way, the use of the technological resources difficultly is guided by the *pedagogical pertinence* of using, but for a *politics of using* based or by for justness of the access to the labs (institutional politics), or by the specific criteria defined by the teacher and his/her area of performance (politics of the pedagogical action).

Once the teacher moves with his/her group of students to the computer lab, the accomplishment of the activities follows the same established regime for the use of the other laboratories. As well as there are itineraries for the accomplishment of experiences and controlled observation of phenomena that corroborate the subject treated in class, also can be a pre-defined itinerary that drives what happens in the space of the laboratories. Visits or guided researches to websites guided by questionnaires, access to content multimedia in CDROM, simulations and accomplishment of exercises guarantees the execution of a script and an assumption reinforcement for the *learning previously scheduled*.

Regarding to the Internet, some schools have as strategy to adopt firewalls (filters) to control the access, impeding that some websites and/or nets are used at the school. In other cases, the teacher is who determines what should be accessed, defining navigation itineraries or a guided navigation, usually to reinforce some subject worked in the classroom. There is, still, cases in that the teacher combines with their students rules of access, defining in agreement that would be appropriate or not in function of the objective of the activities. In all these cases what it is noticed as common element is that the *politics of using* follows a hierarchy that is going from the institution (school) until the classroom space. The fact of the computers and other digital resources be located in an external space of the classroom guarantees to the teacher and the institution to predetermine a plan of actions and some strategy form to guarantee that the epistemological beginning that orientate his/her pedagogic action are carried out in the context of the groups, series or stages of the teaching. Like this, the times and the spaces for the reading, the writing, the research, the exercise, the dialogue, the listening, the work, etc, are defined. Inside of this process, in order to the digital technologies are part of that

context, it is necessary a displacement, a change of classroom context for the space of the laboratory, where, depending on the adopted politics, are refigured, or not, what has been predetermined in the classroom space. This scenery, common in many Brazilian schools, defines a hierarchical and heterarchy cognitive regime, in which the teacher and the school determine mainly what and when to use the TD, as well as it authorizes the spaces of possible inscription to their students. But, and if, instead of moving a group of students for the computer lab, the computer and the Internet enter in the classroom?

THE MODALITY 1:1 AND THE NOTION OF DIGITAL CITIZEN EMANCIPATION
Viñao Frago (2002), when discussing the educational systems and the scholarization, shows the problem of the teaching and learning processes be decontextualized and they depreciate other no school learning. In the extent of the education politics, the author does an analysis of the historical processes involved in the education reforms, their motivations, consequences and resistances. The author shows that the State has to return their attentions for the educational systems in the moments of crisis or after-crisis, intervening or promoting reforms in the sense of provoking new movements in the education processes.

In the current Brazilian context, the relative data to the employability and the demand of technical competences for the new professions that have been appearing, as well as the unbalance of the trade balance in favor of the imports, that demands improvement of the intern production of consumption goods, it has been doing with that the Federal Government invests as well as increasing the offer of technical professional teaching and superior to take an account a supposed "scientific and technological broken" that can happen in ten years.

In front of this scenery of demand for professional qualification in several fields of the work, mainly in relation to the domain of the TD, it understands why the Federal Government is investing in modernization projects from the schools of basic education, besides increasing the offer of the technical and professional teaching. It can be affirmed that there is an understanding that the school has important paper to carry out in the project of national development and to rescue its meaning inside of the project of the citizens' life becomes indispensable.

Inside of this perspective of rescue of the social function of the school in the plans of development national, several initiatives have been created or leaning for the Brazilian Federal Government. Among other politics, the *digital inclusion* has been winning prominence. In front of this complexity of the society introduced by TD in the most several sections, the politics of digital inclusion appear how "(...) need of social agency differentiated to promote the socialization of the individuals to the new cognitive ecology and to the new regimes for it made possible" (Maraschin, 2000, p. 59). In that sense, how the Brazilian education, as in relation to the school institutions as for the public politics, has been inserted in this discussion in order to take an account of this need?

The idea of digital inclusion in the extent of the public politics is going to the encounter of that is noticed in relation to the current national and world social-cultural, scientific and technological scenery, that indicates an use more and more intensive of TD in the construction and in the spread of the knowledge. In that sense, to adapt of TD has become a concern of not producing or intensifying a new pathway of social exclusion, and, in this process, the basic and professional education acquire fundamental importance in the project of Brazilian development.

More specifically in relation to the basic education, the Ministry of Education (MEC) is under the responsibility of developing the Program "One Computer per Student" (PROUCA), that, for the period of two years, it will involve 300 Brazilian public schools, in urban and rural areas, besides the State Department of Education and Nuclei State and Local Technology in Education (NTE/NTM), with the objective: "to create and to socialize new forms of using of the digital technologies in the Brazilian public schools, to enlarge the process of school digital inclusion and to promote the pedagogic use of the technologies of information and communication" (SEED, 2009). The PROUCA brings a new component for the debate around the applied use of the digital technologies in the education, when starts from an innovative model putting portable computers (laptops) in hands of a whole school community - managers, teachers and students.

The new component that the modality 1:1 (one laptop per student/teacher) brings in relation to the previous experiences involving the use of computers in the education is in the fact that, when putting in each student's and teacher's hands a computer, the TD start to occupy a differentiated place. Instead of the computer labs, the own classroom starts to count with this resource, that opens new inscription possibilities and authorship that, at first, extrapolate the institutionalized hierarchy. But which would be the elements of the digital culture exactly that can interfere and produce new cognitive regimes in the schools?

Lemos (2009) defines three laws or beginnings that are in the base of the current cultural process of the *cyber culture*: "(1) the liberation of the pole of the emission, (2) the connection beginning in net and (3) the consequent socio-cultural reconfiguration starting from new productive practices and recombined practices" (p. 39). The first item refers to what the author denominates of "pos-massive culture", in which the individuals have the possibility to produce and to publish information in real time, "under several formats and modulations, to add and to collaborate in net with others, reconfiguring the cultural industry ("massive")" (p. 38). The second refers to the possibility of emitting in net, to connect with other people, "to produce synergies, to change pieces of information, to circulate, to distribute" (p. 40). The third beginning comes from the first two, because the emission and connection produce "the reconfiguration (of practices and institutions) of the massive cultural industry and of the nets of sociability of the industrial society" (p. 41). For Lemos, the understanding of these beginnings (emission, connection and reconfiguration) allows to understand what he calls "informational combining territories" and the socio-cultural impacts of the current digital mobile technologies of communication and information.

Taking these beginnings as base to understand the emergency of a digital culture in the schools, it is added to this proposition the need to understand also as the beginnings of the cyber culture will interfere on the cognitive regimes that orientate the politics and educational practices in the schools. At the same time, these same beginnings and the new cognitive regimes will be capable to provoke transformations at the point of doing with that the teachers and the students be part of that new cognitive ecology? - in the sense of the inclusion, of the authorship and of the active belonging.

The sense of belonging to his/her time and place finds in the idea of digital citizen emancipation a perspective of a quite fertile analysis, because it crosses the subjects merely technological and it enters in the symbolic field of the subjectivity. The digital emancipation involves a "her/him" inclusion, and no simply to be included. Schwartz (2007) affirms that "Processes of digital emancipation look for promoting the displacement of the paradigm of the "society of the information" for a one that has the "society of the knowledge" as horizon, doing of the access just one of the links, necessary, but insufficient, in the productive chain of information that can give sustainability to the economical, social and cultural emancipation of the citizens" (p. 128). The term digital emancipation began to be used in the context of the group of research City of the Knowledge USP/CNPq, founded in 2001, in the context of the discussions on the processes of digital inclusion, in an attempt of overcoming the understanding of the inclusion as access opportunity.

In synthesis, the concept of digital emancipation appears with the pretension of overcoming the mark of the "society of the information" in the sense of thinking ways of integration of the school in the "society of the knowledge", in the which teachers and students can go besides the passive use of the technologies. The imperative is to form nets, connecting learning and life spaces for the corroborate construction of knowledge that enlarge the job and income opportunities. (Schwartz, 2007, p. 129). Starting from this same comprehension, Schlemmer (2010) proposes that it is understanding the "Emancipation and Citizen Digital Education" in a such "level of appropriation, of digital technological fluency, that propitiates to the individual to be a citizen of this time, checking him/her an empowering that makes possible to exercise the social autonomy and the creative authorship, in a dialogic space, cooperative, traversing through the mutual respect and the internal solidarity" (p. 10).

FINAL CONSIDERATIONS

Along what was presented, we consider the definition of qualitative criteria to evaluate government programs that seek to promote a digital culture from the schools.

First, the term *digital inclusion* is insufficient to account for the complexity of this phenomenon, which is culturally and technically, because the idea of inclusion addresses the issue from the point of view of the inability or unavailability of individuals to access to digital technologies. Moreover, the idea of inclusion assumes that the individual or the school has to overcome its way of being or live, their practices, in favor of a new composition, and better than established. Unless this is even the sense to want to give to public policies for education, the said inclusive actions may generate more processes of resistance than belonging, more processes of stagnation than innovatives. We consider that the term citizen digital emancipation is more in accordance with the epistemological principles that define the field of cognitive ecologies as to broaden the discussion inherent to the collective aspects of socio-cultural phenomena.

Under another aspect, we understand that the school simply assign responsibility for the promotion of digital culture is to overlook the fact that the school itself is not yet part of that culture as it operates under its own cognitive regimes of the analog age and not digital. It should be considered that the structural transformations that are revealed in the contrast between the analog and digital cultures require new structural couplings that necessarily passes through the production of new meanings for such categories as

time, authority, modes of entry, hierarchy, etc. Otherwise, digital technologies such as blogs and social networks will not make sense in the classroom, because they are being understood from a cognitive ecology analog, serving only to reproduce what is already done with pencils, notebooks and posters on the walls. What's the point of making public for the whole world what is done in the classroom? Why have a blog? If these simple questions can not be answered by educators and students, these resources can become a simple extension of their traditional notebooks. One proof of this lies in the fact that the Internet is still seen as a large library, a faster and agile way to accelerate the consumption of information in multimedia format. Instead, we must consider how the categories as the emission, connection and reconfiguration will be assimilated into the school, and whether they would cause some change in the established cognitive regimes. Finally, in terms of public politics, to ensure access remains the principle underlying the proposals for digital inclusion, obviously necessary but not sufficient. The democratic use of digital technologies undoubtedly goes by to ensure access, but it is also necessary to take into consideration changes of both the cognitive regimes and the using politics in process in school spaces.

322 - Digital Natives: What and How Much they Learn While They're Playing Online

Cristina M. Pescador

Universidade de Caxias do Sul – Graduate Program in Education
cristina.pescador@ucs.br

Abstract: This paper describes the pilot study carried out for my master's research thesis. The study consisted on individual non-participant observation of 3 Brazilian college students, at the age of 21, who were video recorded while they played. The goal was to identify a few actions they used in order to understand the game and interact in English with other players even though they were not fluent in the language. After the observation, the students were interviewed about their interaction while online. The subjects' actions and their interactions were analyzed from the Vygotskian point of view and the results suggest that this generation – coined as Digital Natives, by Prensky (2001b) – is eager to engage in activities where they can cooperate and collaborate towards their learning.

Keywords: Digital natives, lingua franca, interaction, cooperation, learning.

LEARNING AND TEACHING IN THE DIGITAL ERA

Although parents and educators may think that the time children and teenagers spend in front of a computer is a total waste of time and that it should be used in more productive and constructive alternatives, the young people claim they can learn many things while they are playing games in their computers and surfing the web. Dunkels (2007) says some of them might even hurry home after class, sit in front of their computers in order to connect to the Internet and chat online, exchange instant messages, or interact in social networks with the very same peers they had spent the whole day with at school.

One cannot deny the influence that digital interactive technologies (ITs) have in making it possible for people to develop more autonomy and freedom in their search for information and how they build their knowledge. However, that practice has also influenced the way this generation learns, and it seems time has come to rethink our teaching practices if we want to engage these students in their learning process. The traditional lecture-based practice, where the teacher is the only source of information and where students have to sit still, listen quietly and take notes strongly contrasts with the way digital natives (Prensky: 2001b) or the Net generation (Tapscott: 1998) act when they are outside the classroom. Both authors claim this generation is stimulated and motivated by activities that invite them to interact, that allows them to abandon the position of simple listeners or observers and be active participants.

It is probably not an exaggeration to say that this generations' use of digital media has helped them learn many things they had not learned at school and it is this paper's intention to point out a few findings from a research[118] carried out as an attempt of beginning to understand how Brazilian digital natives are taking advantage of the digital media to learn and improve foreign languages. The focus is to observe and think about what they do that leads towards learning and not to analyze linguistic aspects of their learning. By helping teachers and educators understand *how* they learn, the study might help us rethink our classrooms and our approach to digital technologies in order to engage students in their learning process.

ENGLISH AS LINGUA FRANCA

After years teaching English as a foreign language in Brazil, I was intrigued by how many times I heard students telling me they had learned English by playing video or computer games. What surprised me most was to hear it from people who were taking placement tests to become students at the language program where I work. These placement tests are designed to assess students' knowledge level of the language – except for the very beginners – when they first arrive in order to decide which classes they should attend. I realized there were a great number of young people telling me that they ended up learning the language so

---

[118] Research carried out for my Master's thesis: *Ações de aprendizagem empregadas pelo nativo-digital para interagir em redes hipermidiáticas tendo o inglês como língua franca,* at the University of Caxias do Sul (UCS), RS – Brazil.

that they could interact with their games[119] and with other gamers around the world while playing online. They were not concerned about learning English as a foreign language, but about being able to use it as a common language to communicate with other people online playing the game synchronously or to take part in discussion forums available on the Internet to exchange information and tips with the other gamers.

First, I suppose it may be necessary to enlighten readers on a few aspects that characterize learning a foreign language in Brazil, a country where the mother language is Portuguese. In 1996, there were a few changes in the law ruling educational matters in Brazil (*Lei de Diretrizes e Bases – LDB*) determining that at least one foreign language be taught in all schools from the 5th grade on, and that a second alternative of foreign language should be available in high schools. Before that, having a foreign language as part of the school's curriculum was not mandatory.

However, the conditions in most Brazilian regular schools did not favor teaching-learning a foreign language with the four skills in mind – speaking, writing, reading and listening. In fact, many schools only have one or two 45-50 minute classes a week, for groups of 30-40 students with the most varied levels of English in the same group. That alone would make it more difficult to focus on students' fluency, not to mention that in some schools textbooks and teaching resources might also be an issue, with teachers actually having to prepare and print all the activities and class materials themselves. For all those reasons, a larger focus has been given to teaching reading strategies in schools, considering the social function foreign languages have in the country (Leffa: 1999). If students wanted (or needed) oral fluency, they chose to study English in language institutes[120].

In fact, globalization triggered a need for people all over the world to speak at least one foreign language. Choosing English as the language used for communication between individuals whose first language is **not** English places it in the status of a lingua franca (Crystal: 1997. Graddol: 2006) since people from the most different countries are using it with the sole purpose of communication and negotiation. Although as a lingua franca the language might incorporate aspects of other cultures in order to be used multinationally, that does not mean that it will replace the local languages. On the contrary, native speakers of other languages will naturally incorporate different lexis, accents and culture (Leffa: 2002) into the language they are using as a lingua franca.

Leffa (2002) states that technology has made great contribution to globalization, transforming the world into a digital village thanks to the fusion of computer and satellite. Thanks to this, it became economically viable for millions of people from the most different countries to communicate with one another, propelling the extensive use of English as a common language. It is common sense that today there are more non-native speakers around the world using English to communicate with other people than there are native speakers. One could only expect that this kind of situation inevitably reached the younger generation online.

AN ATTEMPT TO UNDERSTAND HOW DIGITAL NATIVES LEARN

As a digital immigrant in the world of games (video and computer games), despite my curiosity in finding out how digital natives learned with games, I had no idea of what to ask them about their interaction while they were playing online. For that reason, I decided to divide the experiment in two different moments. The first one was to observe them as they played in order to see if a few actions that I pre-organized as categories to watch took place, and to identify other actions that emerged as they interacted with the game. To help me collect that information there was a camcorder installed by the computer screen to record their facial and body expression and a screen-recording software – Camtasia – was installed in the computers to record what was taking place on the screen. The second moment consisted on a confrontation interview, during which I showed certain segments to the subject and asked a few clarifying questions about what was going on in them.

The study was carried out with two male and one female subject, aged 21 years old. They were selected from a group of six volunteers according to a subject profile I had traced before: they should be between 18-22-year-old college students, who were not taking any English courses at the moment, whose level of English could be described as B1[121], and who attributed part of their language knowledge to have been learned by playing videogames and surfing the Internet. They will be referred to by their login names: SeYa, MrWar and Josefina.

---

[119] The word "games" is used in this paper to refer to computer games that can be played on the Internet.

[120] Language institutes are private educational organizations whose purpose is to offer foreign language classes.

[121] According to the language reference descriptions developed by Council of Europe, which range from A1 (basic users) to C2 (proficient users).

Simultaneously to the selection process of the subjects for the experiment, I spent some time choosing a game that could fulfill the characteristics I wanted for it. To do that, I asked some of my students to answer a questionnaire about the topic, on which they could suggest and indicate the games they used to play and liked the best. Then I set up my checklist for the kind of game I wanted. First of all, it had to be free, since I did not have any scholarship to fund my research. Second, it could not be something widely played such as World of Warcraft (WOW), which is the leader of online games in access rates according to surveys. It should have some features described by Prensky (2001b) as "game system", which refers to other media and resources available for players to obtain and exchange information with other players or from specialized magazines, journals, etc – all linked so that this information could be easily found. And it could not offer its players any chance of choosing another language to play other than English. That is how I finally got to Adventure Quest 122, which could be played online, upon log-in only, requiring no downloads to be installed. This was also very important once I was going to use one of the University's computer labs for my research and all I would need would be special permission to turn off the Firewall during the observation sessions by previously informing the IT center of my schedule.

There was one observation session per subject and they lasted approximately 30 minutes each. After that, I watched the video recordings and organized a set of segments per subject to show and discuss with them during the interview. That procedure gave me the opportunity to widen my perspective and guided me through the script for the interview. The interviews consisted of a set of questions that were common to all subjects, regarding their previous experiences with games and another set of questions that were personalized to each observation session.

From their very first login I realized how important had been my choice for the research method. As a digital immigrant, when I was analyzing different games to choose one for the observations, I always started by reading the games' tutorial so I could have a clear idea of what I was expected to do. None of the subjects read the tutorial. All of them started playing immediately after logging in. When I asked each one of them on the interviews why they did not choose to start from the tutorial, their responses were pretty much alike: "because I'd rather learn by doing" and they can do that by exploring the game and observing the consequences of their decisions

This behavior is described by Prensky (2001a) as exploratory learning or learning on the fly, through which digital natives access hypertexts, games and Web by simply "clicking around" in a less sequential manner.

> This new, less sequential information structure has increased the Games Generation's awareness and ability to make connections, has freed them from the constraint of a single path of thought [...] and what has been lost in linearity may have been made up for by a greater ability to perceive, and think in, structure and patterns (p.54-55).

It was possible for me to observe this ability that Prensky describes to perceive structure and patterns in the subjects' interaction with the game. Both MrWar and SeYa justified some of their decisions while playing as the recognition of a pattern in the game. They said that sometimes they start playing a game to see how it works and after they have been able to recognize a few patterns (which would be described in the tutorial had they read it!), they would go back to the beginning of the game and play it again, although this time they would be aware of what to do and how to protect themselves. They also reported that is how they learned many terms, phrases and expressions: by recognizing some kind of pattern in the language use and the consequences of the actions that followed.

Another example of exploratory learning was observed when SeYa's character in the game died in a battle with a monster. He restarted playing and went back to the same scene. When I asked him researcher why he had done that, he said now he knew what had been his mistake while choosing the war tools and equipment for the battle. In the menu of items he had to select, there was a word[123] that was new for him and that he had ignored the first time. When he came back to the scene, he included it in his selection and found out it was the magical protection he needed to win. His words when confronted with the scene were accompanied by a grin, "This time I win, and I'll never forget my spells again!" That consists on a very simple example of how they end up learning a language without even realizing it. As if by accident, a new word was incorporated in his vocabulary in a fun and meaningful way.

---

[122] <http://www.battleon.com/default.asp>.

[123] The word was "spell", which SeYa knew as the verb used to name the letters in a word. He did not know till then that it could be a noun, related to a word or formula that had magical powers. (Definitions from www.thefreedictionary.com)

Like SeYa, MrWar also lost one battle because of a word he did not know in English. His situation was a little more complicated, once he did not include a "shield" in the equipment his character in the game should carry to the battles. He won a few, but the character was badly injured, until he finally died. When confronting the subject with that situation, I asked him if he had any idea of what had happened and he said he suspected he had not included something in his warrior's gear. When I asked him if he would have done anything different had he be playing at home instead of at an experimental situation to which he promptly replied "Sure, I'd put the question in my nick on the MSN, and certainly somebody would help me find out what was wrong." I then asked him if he suspected what could have gone wrong, and he asked to watch the scene again. This time he looked at me and pointed to the word "shield" on the list he was supposed to pick it from, and to the question at the end of the selection "Are you sure you are ready to go to battle?". He then realized the game had given him a hint that something was missing and asked to watch the battle again. His comment was "Of course he lost! He doesn't have a *escudo*[124]!" as he slapped himself on the forehead.

MrWar told me that he had thought about using an online translator to find out what a few things were on the list, but then decided not to, because he felt too lazy to do it. He added saying that he and his friends used to download material for their classes and joined forces to understand and translate things, sharing their findings so "everybody could achieve more". This implies in collaborative work under the Vygotskian perspective of Proximal Zone Development in a classical theoretical concept that refers to the savvier being able to help their peers to learn more.

The female player, Josefina, was the only one to use instant messaging as she played. She first tried to engage her friend in the game too, but they found out something I had not considered when choosing the game. Although the game is designed to have players benefit from others' performance, the option for identifying who the multiple players are is not available as it is in other games. Even so, she continued her chat with her friend, keeping three windows open in her computer screen as she played: one for the game, one for the instant messenger (Google Talk) and another one for her e-mail box, which she checked every now and then, minimizing the other two windows.

Here we can think of a few characteristics of the digital natives described by Prensky (2001a, 2004) and Oblinger and Oblinger (2005): multitasking, sharing information, and an attempt to work collaboratively. We can see Josefina multitasking: playing, chatting with a friend and keeping track of her email messages. Interestingly enough is the fact that she was the subject with the highest score on the game at the end of the observation section. During the interview, she told me that this friend is someone who she usually plays with on multiplayer games and that they used to have a group that organized LAN-parties when they were in high school.

Once again I had to admit my ignorance: as a digital immigrant I had never heard about such parties in Brazil, and I asked her to describe a LAN-party to me. I learned it consists on inviting a lot of people to bring their computers (desktops or laptops) to somebody's house (or apartment), and establishing a local area network – LAN – to play multiplayer computer games for long periods of time – sometimes 24 – 36 hours. If someone got tired and needed to take a rest, another friend would take over and keep the scores up.

In a LAN-party, it is possible to form a clan by adding a word in front of their names so that everyone else playing with them online will know that they are a clan or a group. Then this clan would sometimes play against another clan and the whole interaction among the players would be through an instant messaging tool of the game and the language used would be English, regardless the origin of the players. Clans or groups are stronger and have more chances of winning than other gamers who are playing individually.

Josefina told me that people who use Portuguese or some other non-English language while playing online can be ignored by other multiplayers for the simple reason that people will think it will be hard to communicate with somebody "who doesn't speak the new Latin".

This description of a LAN-party clearly shows how cooperation and collaboration are common actions of the digital natives when interacting online with their peers. It also evidences the use of a lingua franca by the players, referred to by the subject as "the new Latin".

During the whole process of collecting data for the study and analyzing it, one thing called my attention: there was a great interest from the students who had helped with the questionnaire with suggestions of games and from the subjects of the study itself on knowing if I had already compiled the results. Many of them came to me with new suggestions of games I could use in further studies or papers they had found on the Internet and thought I might be interested in reading. I suppose this proactive attitude can be added to the many traits used to describe digital natives.

DIGITAL NATIVES FROM THE VYGOTSKIAN PERSPECTIVE

Van Der Veer and Valsiner (2009) claim that Vygotsky was especially concerned with the whole process of learning, and this idea was expressed in the Russian word *obuchenie*, which was originally used to describe the teaching-learning process. Vygotsky's studies were focused on the social determination of an action, which always had a need to fulfill and the mediations toward this fulfillment. He considered man to be an interactive being, whose knowledge came from mediation processes that allowed transforming nature and himself through the use of instruments and tools that had been socially built.

Even though the subjects of this pilot-study were not aware of their learning process while playing, we can say that playing computer games creates a situation where they need to take action in order to achieve goals or fulfill that need. And considering knowledge as the result of the action between subject and object (Vygotsky: 1998), their knowledge of a foreign language, for example, can be built as they achieve their goals in the game mediated by a foreign language. In their search for a solution to the situation (winning the game), they need to understand the language signs, trying to make sense out of them so they can make the necessary decisions to move forward.

As educators, we could transpose this to learning situations mediated by digital and interactive technology, where students could be challenged to obtain information and solve situations by communicating and interacting towards a common goal. I assume that as digital natives they would naturally tend to build some kind of cooperation or collaboration network that would help them achieve their goals. This would certainly call for a new paradigm in our teaching practices as well as it might engage our digital learners once it takes into account how they learn and interact. It would force students to develop thinking and investigative skills, becoming critics (Tapscott: 1998) as they have to analyze situations and make decisions.

This approach would straighten the distance of what digital natives do at home from what they do at school. They want to share and collaborate, contributing to other peoples' learning. That can be inferred from the discussion forums found in the website of the game used in the observations, and from the proactive behavior shown by the subjects of my study and my students towards the research they knew I was carrying out.

In the forums for the game used for the study, I found many postings revealing details and secrets on how to move forward on the game. If this could be applied in classroom activities we would have the possibility of watching students helping each other, trying to solve situations that they have been confronted with before, creating real zones of proximal development in their interactions.

If we think about how digital natives like (and maybe need to) multitask, we could start thinking of ways to propose learning activities where they needed to use several abilities at the same time, just like the female player did during the observation and the way we can probably see digital natives studying when they are not in their conservative and traditional classrooms. Once again by doing that we could wear lenses from a Vygotskyan perspective, since for this author learning means acquiring many abilities to think about several different things (Vygotsky, 2001). According to him, social interaction has a major role in the cognitive development and it is the teacher's role to help learners associate what they know to a literate and scientific language, aiming at the enhancement of their knowledge and at their historical and social integration into the world. So how can we explain that teachers still insist on students' sitting quietly and passively in their classrooms while teachers lecture?

IMPLICATIONS FOR SCHOOL AND TEACHING PRACTICES

Wouldn't it make more sense to have students bonding and teaming up on cooperative and collaborative tasks, as they do when they play online games from their homes or even when some of them form clans to play in their LAN-parties? It has been widely said that digital technologies, especially the Internet, can enable learning experience to be centered on the learner himself, as he explores the subject in a somewhat "discovery" mode, as they learn on the fly (Prensky: 2001a, 2004). And yet nothing seems to be further than that than their daily school experiences.

Our difficulties as teachers, parents and educators to understand what digital natives do on the Internet and on their use of digital media must be addressed and overcome, and we need to rethink our teaching practices and create – or learn how to use – new pedagogical tools. That does not mean we need to be fluent in the digital language, though. But neither does it mean we can insist on leaving digital technologies out of our classrooms. There is no use in having modern computer labs and interactive boards in school if the way we teach remains the same. Teaching and learning has to be dynamic, with full involvement of all actors in meaningful and constructive experiences, and we need to struggle with the teacher-centered attitude that has grown deep roots in the way we think and plan our lessons.

Teaching practices for digital learners must bear in mind that they are sharing people, who like to be active participants in the tasks they need to carry out and that they will tend to do things in a collaborative and cooperative kind of way. Studies being carried out indicate that this kind of practice will probably engage students, helping them make sense of what they are learning and thus making learning a meaningful – and why not – fun experience.

This study was just a glimpse into the way this generation learns on the fly, exploring, interacting, teaming up thanks to social networks and computer games, in a way that was unimaginable for their parents and educators. As an EFL teacher and as a teacher educator, it was my intention to look beyond the computer screen and games and try to understand how digital culture and its multifunctionality have influenced the way people learn. By doing that, we might have the basis necessary to rethink and modify our teaching practices, putting aside the role of the teacher as the one who transmits knowledge – as Freire insisted throughout all his work – and being able to learn with and from students as well. And then classes might probably become more motivating and students will certainly be more interested in being part of their learning process. Teachers and educators might even not have to worry about discipline in their classes as much as we have been doing in the last couple of decades.

mfreszka@zipmail.com.br

Abstract: This article linked to the UNISINOS/CNPq Research Group for Digital Education reflects upon the metaphor of hospitality and suffering psychological among trainee teachers in front of digital technologies, which involve the knowledge of new subjects that inhabit the school, this teacher training and the "zapping" student - virtual citizen, who can zap, using multiple digital technologies at the same time (Veen and Vrakking, 2009), which will depend, not only of understanding the suffering resulting from the experience of self and other but before any involvement of changes in that context. Aims to analyze the changes in the context of education before the use of digital technologies (DTs) and the psychological suffering of this process, to (re) think about teacher education. Within the UNISINOS/CNPq Research Group for Digital Education as a methodological approach, we are doing a literature review of the use of technology in school, aiming to articulate the Theory of the Hospitality Metaphor seeking answers next to Psychoanalysis to understand the psychological suffering teachers. In addition we are beginning to apply semi-structured interviews to collect data and analyze them. The aim is also to listen to these teachers, seeking to understand the time that those are living. In the Theory of the Hospitality Metaphor (Ciborra, 2002), hospitality is the behavior that reveals the human effort to cope with the uncertainty that is always involved by hosting a new technology: during the hosting process, you can discover the new technology as a very nice guest, or it may instead prove to be an enemy, stealing the territory of the host and making him a hostage. And, thus, triggering fears, causing suffering. Suffering is an interweaving of the subjective conditions and the conditions objective historical-cultural (Aguiar & Almeida, 2008). The same authors point to a teacher malaise as a psychological symptom, which stems from the intertwining of body and social discourse and the subject's fantasy. To Murta (2001), the teachers's psychological suffering should be seen as the expression of an internal conflict experienced within the profession, a conflict that betrays a profound malaise that encompasses both the professional and personal aspect. Esteve (1999) describes the teacher's malaise to understand the permanent effects of a negative character, which affect the personality of the educator as a result of psychological and social conditions in which teaching has, due to accelerated social change. As research is underway, looking up through this article, provoke a broader discussion on these aspects and possible symptoms of this comes from.

Keywords: hospitality, suffering psychological, teacher training, digital technologies.

INTRODUCTION

We know how positive the use of different Electronic Technologies may be in teaching and learning processes, however we also know how freighting it may also be. There are students today that are breaking into teacher's as well as colleagues' privacy, generating phenomenon such as cyberbullying, what generates angst among the ones related to the fact. These technological resources, that primarily should help and facilitate people's life in all areas, unfortunately are being used in inconsequent and perverse fashion, underestimating and insulting other people, therefore causing severe consequences and harm to the victims. This new reality that discloses to us is very concerning and thus we believe that it is urgent for us to address these thematic in the construction the docent.

The challenge of reflecting about this thematic that comprehends the knowledge of these individuals that exist in the school, the teacher under development and this flipping student will depend not only on the understanding of the suffering that comes from the violence to himself and others, but of a complete involvement ahead changes on this mater.

At this point it is essential to reflect and plan actions about the following topics: What student do we have in class today? Is the teacher searching for information to manage with this new student and electronic

technologies? Is there psychological suffering from that? How is it revealed? Is there virtual violence is this process? Altogether, the school seems to be the stage for all this problematic of interpersonal relations, so intense and so delicate where it happens. Can we conceive education that is capable of teaching and learning in this context?

Thus, the objective of the study linked to the Research Group for Electronic Education - Gpe-dU UNISINOS/CNPq is to analyze these questions in the context of education, facing the use of Electronic Technologies (ETs) and the psychological suffering that comes from this process, so we can (re)think the docent development.

CONTEXTUALIZING TECHNIQUE, TECHNOLOGY, WIRED SOCIETY...

The beginning of human evolution and, consequently, the beginning of the first societies have been marked by the influence of technology. As remembered by Lemos (2002), we can mention some examples such as: discovery of fire, the cultivation of the land, animal domestication, construction of cities, control of energy, construction of industries, the domain of the cosmic, the trips deep into the mater and the space-time.

Lemos (2002) mentions that etymologically the term Technique comes from greek tekhnè that can be translated as art. Accordingly, *tekhnè* comprehends the practical activities, from counting and measuring skills to plastic arts or fine art, considering these last two the highest expression of human skill. Thus, technique can be described as proceeding or group of proceedings that aims a certain result being it in the Field of Science, Technology, Arts or other activity.

As a complement, Lemos (2002) mentions that from the XVII century on, the technical activity begins to relate to scientific knowledge, this process results in means of Research and Development Centers in the XX century, and thus determines the definitive junction between science and technique. Thus,

> We can say that the prehistoric technique is a product from empiric experience of the world, without needs for scientific explanations (the first tools, instruments and machines). The technique is the subject of a transforming human that prepares nature for the formation of the species and human culture. It is a provocation from nature that generates a process of ordinarization of technical objects in the construction of a second order that is inhabited by organic matter, inorganic matter and organized inorganic matter (technical objects). (Lemos, 2002, p. 40)

What we call today technology or modern technique is exactly the ordinarization of technical objects ants their fusion with science. At this point, nature and social life are required as objects of technical- scientific intervention.

According to Castells (2005), a technological revolution is centered in information technology and communication is remodeling the material basis of society in an accelerated rhythm. There is an intense and growing movement in interactive computer networks, which creates new ways and channels for communication, modeling life and being simultaneously being modeled by it. Thus, the fast evolution in technologies and telecommunication generates changes in all sectors of society, that contributes to the creation of the so called "Online Society". Lemos (2002, p. 147) says that "today net means a telematic structure linked to interactivity concepts, together with circulation and tactility[iii]".

> [...] technology does not determines a society. Neither does society directs the course of technologic transformation. [...] the final result depends upon a complex interactive pattern [...]. Technology is the society, and society cannot be understood or represented without its technological tools. (Castells, 2005, p. 25).

However, Castells (2005, p. 26) adds:

> without any doubt the ability or inability of societies to control technology and especially those technologies that are strategically decisive to each historical period, leads to a point in which we can say that although it does not determines the historic evolution and the social transformation, technology (or the lack of it) incorporates the ability of transformation of societies, as well as the usages that the societies always in a conflicting process, decide to dedicate to its technologic potential.

In this online developing society, the technologic transformation process exponencially expands according to its capacity of generating an interface between technological fields, through a common digital language, in

which the information is generated, stored, recovered, processed and transferred. According to Castells (2005, p. 50), "new information Technologies allow at the same time, decentralization of tasks and its coordination in an interactive network of real-time communication, be it across continents, or be it across storages of the same building.". (p. 286)

The planet is immersed in a global culture that is launched with the advent of the media attached to the ETs, called cyberculture.

For the sociologist André Lemos (2006, p. 10),

> [...] the development of cyberculture starts with micro-computers in the 70's, with technological convergence and the establishment of the personal computer (PC). In the 80-90's, we witnessed the popularization of the Internet and transformation of the PC into a collective computer (CC) connected to the cyberspace.

For Lemos (2002), cyberculture is the association of contemporary culture to ET's, combining technique with social life. These are our new ways of life permeated by instant communication, the speed of information, the possibility of intervention and creation of new information that primarily characterizes cyberculture.

Lemos (2002, p. 93) shows that,

> Cyberculture will be characterized by the creation of a established society through a generalized telematic connectivity, widening the potencial for communication, providing a broader possibility for ways of information exchange, fostering social aggregations

Lemos (2002, p. 281) also complements:

> the press, radio and television deliver daily news on this cybernetic front (internet, cell phones, pagers, PDA, CD-ROM, virtual reality, etc..) as a reflection of our society that becomes increasingly impacted and transformed by the simulation, the communication network and the micro-machines that colonize our daily lifes.

Another characteristic in Cyberculture is that the old ways of life are not canceled, but reconfigured. Thus, according to Lemos (2002), things that we once did in a certain way, have now its own logic, space and time changed due to the advent of ET's connected in network. For example, going to the bank no longer depends on a physical movement. With a few clicks you can: transfer, deposit, purchase and pay, i.e. perform several monetary transactions. You can also talk with several people simultaneously, at different places, without leaving home. There is a sense of omnipresence in cyberculture. The mass media lose their meaning in a culture where everyone can post their thoughts, ideas, poems, and even cause self promotion of oneself, furthermore manipulate images, sounds, post, send, copy and paste. The liberation of these upload centers is typical of ET's and the network, with the horizontalization of the power of emission and reception: the information is no longer to be transmitted but to be dialogued. Moreover, in cyberculture, the figure of the spectator is almost nonexistent because everyone can potentially generate and deliver information[iv].

Thus, cyberculture indicates a new model of living and relating one with each other. Respect to another is fundamental in network culture, in culture, because no one communicates alone and the network only exists in the intersection of several "us".

These modifications in social forms, practices of cyberculture, also bring up changes in relation to the daily life of the teacher, related in the process training and in the practice of these subjects.

DAILY LIFE OF THE TEACHER FACING ELECTRONIC TECHNOLOGIES

Papert (1994), scientist-professor and one of the founders of the MIT Artificial Intelligence Laboratory, was one of the responsible at the end of the 70's, by the great advancement for the use of computer science in Education. On his book Mindstorms: Children Computers and Powerful Ideas, Papert refers that we cannot forget the child that exists in each one of us, and that she has not been suffocated, but is kept alive across the professional career, and allows and we can not forget the child within us all, and that she had not been suppressed, keeping her alive in her career, letting her deeply human profile to be expressed. One of his ideas is to make the student the subject of the learning process and not object.

In corroboration with this, Freud (1976b) states something similar, saying: "The only ones that can be pedagogue are the ones able to penetrate the child's soul, because we adults do not understand our own childhood."

In the late 80's a new generation is born that has added several denomination, electronic generation, network generation, cyber-generation, electronic progeny, names that refer to specific characteristics of their environment or behavior.

When we think of *homo sapiens*, the wise man, an expression used by Henri Bergson, to indicate the man, the only intelligent animal compared to others, and the *homo zappiens*, here called the virtual citizen, who can zap, using multiple electronic technologies at the same time (Veen and Vrakking, 2009), we realize that a world of differences are configured between one being and another, between the educator and student today. We therefore need further study of these taken positions, because we know little of them, and they are part of our everyday life, whereas the educator from an analog era and students from the electronic era.

Within this context, Alonso (2007) discusses a life-long learning in education and teacher development as a priority theme of the late twentieth century and the beginning of the XXI century. Alonso (2007), when reflecting on the issues and the origins of the debate about the need for a continuing education, he highlights some illusions embedded in the educational tradition about the potentialities of teacher development:

> "a) the illusion of professionals as having all the necessary knowledge to the needs and problems of children and young;
> b) the illusion that the education sciences constitute a coherent field of rational and applicable knowledge, that can be transmitted in systematic courses to prospective teachers;
> c) the illusion that docent professionalism is resulting from the achivement of a magic academic training, usually more or less separated from problems and daily practices of the schools;
> d) the illusion that a professional as being able to educate students for life and work upon which he does not know enough;
> e) the illusion of the professional as being server of the State that is above social classes, without getting involved politically in their contradictions and antagonisms. (Alonso, 2007, p. 44)"

The concept of educating persists in this environment, and along with that more ambiguities, since the term in its origin may be ascribed to *educatio*, as well as to *eductio*. Campbell (2006) brings us this distinction by pointing out that the first refers to actions for growing, nursing, taking care, teaching a child. The second refers to the condition of bring out, force out, take out, finally, give birth, so that we may reflect the movement in which we belong, putting in and helping to put out, letting grow, revealing themselves.

The so called "technological revolution" affects even more these concepts, because, as we know that to educate process assumed by the scholarization and the social task of transmitting the historically accumulated knowledge to the Young generations, and the teacher played the mains source of this process, this one possessed the cultural accumulation and the professional knowledge's, which were transferred to the students. This place is being questioned; pointing out that there is no social sense in the function of the teacher that is based on transfer of knowledge. That is reflected in the field of authority, and putting in check our profession (Cunha, 2009).

The main job from authority is to authorize, authorize to be, to grow, to learn, to be recognized and respected on its human dignity, without exclusions. Authority as authorization, is according to the etymology of the word, (*auctoritas, auctor*), id est, to increase the power of life and of personal affirmation, to grow, to be the author (Guillot, 2008). This one also brings to us two manners of being author in education. One consists in wishing to be author of someone else, corresponding to the authority that prohibits one of becoming someone else, therefore an authority that destroys. The other is the one that authorizes the individual to become independent, therefore the authority that constructs.

We need in this way to recover the authority in education, because we know that same is in bad shape. We need to analyze three references ahead of that. The first one comes from a change of paradigms in our society, because the models identified are different ones. Today the teenagers are models. THe attitudes related to time, the "now" and "here" rules the game of desire. The second one is related to fear and authoritarianism facing the collective representatives, and the last one is about the role of the teacher currently (Guillot, 2008).

Sousa Santos (1998) also names this crisis of legitimacy and authority that we are facing, because the university tradition is no longer managing its own practices, therefore being systematically questioned. Access to information brought great changes and these have consequences to the pedagogic act.

Facing this access and so we can understand how the acceptance process that occurs for a new technology by the subject, we will make use of the Hospitality Metaphor from Ciborra[v](2002).

HOSPITALITY METAPHOR

In the theory of the Hospitality Metaphor, proposed by Ciborra (2002), technology is treated as a guest. This guest should be understood as a guest which we accept to live with us or as someone who may be hostile. In this context, hospitality refers to treating this technology with the look of a stranger and ambiguous, as by allowing and accepting this "guest", we may consider it a friend or an enemy.

According to Saccol and Reinhard (2005, p.2),

> hospitality is then behavior that reveals the human effort to cope with the uncertainty that is always involved by hosting a new technology: during the hosting process, one can discover the new technology as a very pleasent guest, or at contrary, one can be proven as an enemy, stealing the territory of the host and making him a hostage..

Ciborra (2002) says that dealing with this uncertainty, this ambiguity, in this way, to reflect about what the technology represents, can be considered the essence of the hospitality. By the opposite, this hosting process can be configured in an empty process, passive and insignificant. Thus, the true hospitality can be considered as the behavior that is revealed in the human effort in dealing with the uncertainty and the mystery of hosting an estranger.

Thus, by adopting a technology and hosting it in our routine it is often necessary for us to readjust our commitments related to the new technology (organization, autonomy, etc), work processes and routines. By redefining, we are reinterpreting our own identities.

Regaring this aspect, Ciborra (2002) puts that we should consider that hospitality can imply in a negotication between the novalty that hás been introduced by the host (external world) and the world in tis context, internal (its organization, its daily activity). It is precisely this confrontation between internal and external world in hosting technology (guest), that we can strengthen, enforce or even change our identities.

This process is full of tensions, as both the host and the guest may become hostages of each other. So, this is a kind of relationship should be based on trust

The theory of the Hospitability Metaphor visualizes this process of adoption of a new technology as a learing process that involves trial and error, improvisation and knowledge construction in an informal manner. It may occur in the "hosting" process, adaptations, new uses of technology which have not been foreseen when it was created, improvisation, among others. Ciborra (2002) puts that people will interact and seek to adapt the technology, making the familiar what is strang

Saccol and Reinhard (2005, p.2) mention that

> As a result from this process, technology by going on drift, that is, it may server for unpredictable objectives, it can be used in a distinct way that it hás been palnned for, or suffer an adjustment according to the real context in wichi is is being applied. It is only by means of continuous interaction between people and thechnology that we can veryfy the effective results of its implementation.

The hospitality metaphor calls attention to emotions, also known as moods[iiii], of subjects during the process of hospitality of a new technology.

Saccol (2005) also mentions that people that develop an emotional linkage to events and artifacts (in this case móbile devices), which cannot be ignored. Thus, the process of hospitality calls attention to the biographical, ethics and historic characteristics of the persons related to the implementation of a given new technology.

Saccol e Reinhard (2006) describe the main propositions related to the Hospitality Metaphor, a such:

- When hosting a new technology we reinterpret our identities.
- Host a new technology involves learning by doing and improvisation.
- During the process of hosting technology may drift away.
- Hospitality involves moods and emotions.
- Hospitality refers to the ownership and care.
- Hospitality involves cultivation.
- We can not forget the dubious nature of technology: technology can become an enemy.

Finally, the hospitality implies an appropriation and interest of people for the new technology, becoming thus a successful hosting, which consequently leads to the disappearance of this technology in daily life of the subject, integrating the routines and work contexts so that over time tends to become ordinary. Through the Theory of Hospitality we can interact with the new technology without following pre-established steps, thus dealing with the unknown and the unpredictable, just like the way in which the daily activities are configured. The space that this new technology will take should not be constantly reflected.

PSYCHOLOGICAL SUFFERING

According to Reszka (2005), there is an inversion in the role of authority, since there is no difference between the teacher's authority over what to do with the student and in relation with the authority that the student has been possessing at school over the teacher. From this perspective, teachers feel lost, frustrated and frightened facing the lost authority, and therefore the aggressiveness and violence that have appeared in the school environment.

All this context describes a teacher permeated by suffering, anguish, uncertainty and stalemate. Suffering is an interweaving of the subjective conditions and the objective historic-cultural conditions (Aguiar and Almeida, 2008). The same authors point out to teacher's malaise as a psychologycal symptom, which rises from the intertwining of the body with the social discourse and the fantasy of the subject.

A psychic symptom must be understood as a subjective phenomenon that is not a sign of disease, but the expression of an unconscious conflict (Chemama, 1995). The symptom is then a formation of the unconscious, structured like a language; it is the truth of the subject that emerges in the failure of knowing and that is manifested by the teacher in his suffering, yelling, causing symptoms, metaphorising his anguish, which often is not recognized.

In The Malaise in Civilization (Freud, 1976b) has already stated to be the work of the sources of the malaise in the culture, because it generates conflicts in the subject and a sense of estrangement and unhappiness, because the fact of commitment in relationships with others triggers one of the greatest sufferings.

In Inhibition, Symptom and Anxiety, Freud (1976a) called the subjectivity of helplessness, which refers to distress with interpersonal relationships, social relationships and any structure of the subject, and we know that this helplessness is what establishes the malaise in contemporary society.

Esteve (1999) describes the expression docent malaise for us to understand the permanent effects of a negative character, which affect the personality of the educator as a result of psychological and social conditions in which he performs the teaching due to the accelerated social change.

That signalizes that the teachers are becoming ill, and we are stopped in time, without rethinking our everyday life, without articulating the dimensions of teaching and research in places and sites of training, as pointed out by Cunha (2009).

By collaborating, Guillot (2008, p.118) tells us that training is at the heart of the problem: "[...] the necessary critical analysis should not restrict speeches as the formalism of good cultural quality: teaching practices that should be lit."

FINALLY WHAT HAS TO BE CONSTANTLY REFLECTED…

With the aim of bringing some questioning toward the teachers development, regarding electronic Technologies, we can share with you all pragmatic changes in which we are surrended, since half of the XX century, whit the advent of the nuclear bomb and the electronic technology, marking in this way the birth of the post-modernity as an era of change.

The condition of the teacher and subject today, hosting or not the technology, shows us that suffering may or may not occur. It is important to bring upon that hosting this technology involves a constant "coping with" access to the world, thereby constraining the privacy of the subject, marking fractures as to time, space and ethics of this teacher and subject. At the same time, not hosting the technology, is to feel excluded from that process, influencing the way of looking at school and those students who work daily with these electronic technologies, creating suffering and angst when he begins to consider his practice in the world, being often a hostage of technoscience.

In this context, we must review how the training institutions are making room for such discussions, particularly ahead of College Pedagogy, of current syllabus and the suffering that comes from this process as a comprehensive social symptom.

355 - From Homo Sapiens to Homo Zappiens: Psychological Suffering of Teachers Before the Digital Technologies

Maria de Fátima Reszka

Postgraduate Programme in Education – University UNISINOS;
University ULBRA Gravataí, University FACCAT, Brazil
mfreszka@zipmail.com.br

Abstract: The subject described as from homo sapiens to homo zappiens makes us think the social changes to which we are immersed, from the wise to the zapping man, with behaviors and feelings that are believed to be completely different, which generates psychological suffering of the teachers and making us think the teacher development facing digital technologies. Based on the need to reflect, discuss and plan interventions because we are immersed in changes, this way generating dilemmas and agony in teachers, who need to be better investigated. The contextual and cultural factors in which we are emerged will be identified, as well as the changes that we are undergoing and what the result is, considering the student and the teacher positions. Based on this finding, it is the responsibility of the formation agents to introduce practices which seek to review the College Pedagogy in order to face this problem that affects the Education. The present ongoing research, by identifying and analyzing theories that underlie the changes occurred in the last twenty years of the new technology, aims at bringing up the teacher's psychic suffering in face of these facts, trying to reflect and plan actions on the following questions: What student is this one we have in the classroom nowadays? – Has the teacher sought formation in order to deal with these new students and the digital technologies? – Is there psychic suffering from that? – How does it manifest? – Is there virtual violence in this process? School seems to be the venue for this whole problem of interpersonal relations, which is so intense and fragile; the place where this can becomes evident.

Keywords: Psychic Suffering. Electronic Technologies. Education.

Papert (1994), scientist-professor and one of the founders of the MIT Artificial Intelligence Laboratory, was one of the responsible at the end of the 70's, by the great advancement for the use of computer science in Education. On his book Mindstorms: Children Computers and Powerful Ideas, Papert refers that we cannot forget the child that exists in each one of us, and that she has not been suffocated, but is kept alive across the professional career, and allows and we can not forget the child within us all, and that she had not been suppressed, keeping her alive in her career, letting her deeply human profile to be expressed. One of his ideas is to make the student the subject of the learning process and not object.

In corroboration with this, Freud (1976b) states something similar, saying: "The only ones that can be pedagogue are the ones able to penetrate the child's soul, because we adults do not understand our own childhood."

In the late 80's a new generation is born that has added several denomination, electronic generation, network generation, cyber-generation, electronic progeny, names that refer to specific characteristics of their environment or behavior.

When we think of homo sapiens, the wise man, an expression used by Henri Bergson, to indicate the man, the only intelligent animal compared to others, and the *homo zappiens*, here called the virtual citizen, who can zap, using multiple electronic technologies at the same time (Veen and Vrakking, 2009), we realize that a world of differences are configured between one being and another, between the educator and student today. We therefore need further study of these taken positions, because we know little of them, and they are part of our everyday life, whereas the educator from an analog era and students from the electronic era.

Within this context, Alonso (2007) discusses a life-long learning in education and teacher development as a priority theme of the late twentieth century and the beginning of the XXI century. Alonso (2007), when reflecting on the issues and the origins of the debate about the need for a continuing education, he highlights some illusions embedded in the educational tradition about the potentialities of teacher development:

> "a) the illusion of professionals as having all the necessary knowledge to the needs and problems of children and young;

b) the illusion that the education sciences constitute a coherent field of rational and applicable knowledge, that can be transmitted in systematic courses to prospective teachers;

c) the illusion that docent professionalism is resulting from the achivement of a magic academic training, usually more or less separated from problems and daily practices of the schools;

d) the illusion that a professional as being able to educate students for life and work upon which he does not know enough;

e) the illusion of the professional as being server of the State that is above social classes, without getting involved politically in their contradictions and antagonisms. (Alonso, 2007, p. 44)"

The concept of educating persists in this environment, and along with that more ambiguities, since the term in its origin may be ascribed to *educatio*, as well as to *eductio*. Campbell (2006) brings us this distinction by pointing out that the first refers to actions for growing, nursing, taking care, teaching a child. The second refers to the condition of bring out, force out, take out, finally, give birth, so that we may reflect the movement in which we belong, putting in and helping to put out, letting grow, revealing themselves.

The so called "technological revolution" affects even more these concepts, because, as we know that to educate process assumed by the scholarization and the social task of transmitting the historically accumulated knowledge to the Young generations, and the teacher played the mains source of this process, this one possessed the cultural accumulation and the professional knowledge's, which were transferred to the students. This place is being questioned; pointing out that there is no social sense in the function of the teacher that is based on transfer of knowledge. That is reflected in the field of authority, and putting in check our profession (Cunha, 2009).

The main job from authority is to authorize, authorize to be, to grow, to learn, to be recognized and respected on its human dignity, without exclusions. Authority as authorization, is according to the etymology of the word, (auctoritas, auctor), id est, to increase the power of life and of personal affirmation, to grow, to be the author (Guillot, 2008). This one also brings to us two manners of being author in education. One consists in wishing to be author of someone else, corresponding to the authority that prohibits one of becoming someone else, therefore an authority that destroys. The other is the one that authorizes the individual to become independent, therefore the authority that constructs.

We need in this way to recover the authority in education, because we know that same is in bad shape. We need to analyze three references ahead of that. The first one comes from a change of paradigms in our society, because the models identified are different ones. Today the teenagers are models. THe attitudes related to time, the "now" and "here" rules the game of desire. The second one is related to fear and authoritarianism facing the collective representatives, and the last one is about the role of the teacher currently (Guillot, 2008).

Sousa Santos (1998) also names this crisis of legitimacy and authority that we are facing, because the university tradition is no longer managing its own practices, therefore being systematically questioned. Access to information brought great changes and these have consequences to the pedagogic act.

Facing this access and so we can understand how the acceptance process that occurs for a new technology by the subject, we will make use of the Hospitality Metaphor from Ciborra (2002).

The challenge of thinking over this theme relates to the knowledge of this new subjects that inhabit the school, this developing teacher and this zapping student will depend not only in understanding this suffering that comes from his own the other's experience per se, but also from the understanding of the suffering that come from experience of himself and the others' but the relation of all changes in this context.

We know the extent of the benefits that these technologies bring into education, but we know how frightening it is. Today we have students breaking into the privacy of teachers and classmates, generating phenomena such as cyberbulling, generating angst among the parties involved. Such technological devices, that should be primarily to support and make people's life easier, are unfortunately being used in an inconsequent and mean manner, sub-judging and insulting other people, which cases severe consequences and damage to the victims. This new reality that is being revealed to us is worrying and we believe that it is urgent to work with it in terms of teacher development.

Working in two Universities, I have been noticing a great shift in term of learings, we often perceive constant challenges in this field, where teachers express fear in dealing with technology, while others smoothly became skilled to develop works that are directly linked to technology, making use of existing databases, bring criticism and allowing the student to experience his creativity and explore his knowledge in the field of learning. We can think several things from that. Would these teachers be on one side phobic in relation to technology and on the other side, stewards of change in the current universe?

Therefore, face to an academic and professional path, in which in ten years; I have already been preoccupied in listening to the teachers to understand the social symptom named as violence in the school, today the urgency for the continuation of research in this field is justifiable, because of changes in which we are immersed, from wise man to zapping man, the violence that we are facing, because there has been noticed several cases of teachers being humiliated, disparaged and insulted in sites and blogs, and being psychologically affected.

In Brazil, Wanderlei Codo (1999) studied about the educator desistance syndrome, the burnout that takes to the physical and mental illness, bring very serious questions to the field of education. He indicates us that the burnout appears when there is a combination of institutional demands, the role of the teacher and personal issues related to perfection. Our reality shows us overloaded classrooms, too many administrative and bureaucratic processes, children with learning difficulties that have to be addressed individually and the teacher in front of this reality self-expecting not to fail.

By reflecting what Faber (2001) and Codo (1999) name, we know that the common symptoms are insomnia, headache, ulcer and hypertension, because the teachers somatize these symptoms when their defenses fail, theis demands are big and the results are small thus generating a great suffering, that exposes the teacher to several "stressing agents" that become harmful to the teacher's health.

In some pieces of records we find the teachers in panic and ahead of a great pedagogic action: "I know the machine, I am fluent in the technology, but I don't know what to do. A student comes to me and say: 'I will do that'! I cannot create anymore, innovate. I think that my time is gone. I have been taking until I got ill, I had a hart attack in front of the computer."

According to Reszka (2005), there is an inversion in the role of authority, since there is no difference between the teacher's authority over what to do with the student and in relation with the authority that the student has been possessing at school over the teacher. From this perspective, teachers feel lost, frustrated and frightened facing the lost authority, and therefore the aggressiveness and violence that have appeared in the school environment.

This entire context describes a teacher permeated by suffering, anguish, uncertainty and stalemate. Suffering is an interweaving of the subjective conditions and the objective historic-cultural conditions (Aguiar and Almeida, 2008). The same authors point out to teacher's malaise as a psychologycal symptom, which rises from the intertwining of the body with the social discourse and the fantasy of the subject.

A psychic symptom must be understood as a subjective phenomenon that is not a sign of disease, but the expression of an unconscious conflict (Chemama, 1995). The symptom is then a formation of the unconscious, structured like a language; it is the truth of the subject that emerges in the failure of knowing and that is manifested by the teacher in his suffering, yelling, causing symptoms, metaphorising his anguish, which often is not recognized.

In The Malaise in Civilization (Freud, 1976b) has already stated to be the work of the sources of the malaise in the culture, because it generates conflicts in the subject and a sense of estrangement and unhappiness, because the fact of commitment in relationships with others triggers one of the greatest sufferings.

In Inhibition, Symptom and Anxiety, Freud (1976a) called the subjectivity of helplessness, which refers to distress with interpersonal relationships, social relationships and any structure of the subject, and we know that this helplessness is what establishes the malaise in contemporary society.

Esteve (1999) describes the expression docent malaise for us to understand the permanent effects of a negative character, which affect the personality of the educator as a result of psychological and social conditions in which he performs the teaching due to the accelerated social change.

That signalizes that the teachers are becoming ill, and we are stopped in time, without rethinking our everyday life, without articulating the dimensions of teaching and research in places and sites of training, as pointed out by Cunha (2009).

By collaborating, Guillot (2008, p.118) tells us that training is at the heart of the problem: "[...] the necessary critical analysis should not restrict speeches as the formalism of good cultural quality: teaching practices that should be lit."

As my formation has been constructed from Pedagogy to Psychology, I believe that I can bring contributions to work in the theme, bring light from psychoanalysis to support seeing the subjects involved in this scheme, and the suffering that transpose this field of Education so we can foresee the use of new electronic technologies with ethics and commitment in the process of knowledge construction that prioritize the interdisciplinarity.

355 - M-learning in the Process of Teaching and Learning: Reflections and Opportunities*

Paulo Gaspar Graziola Junior

Postgraduate Programme in Education – University UNISINOS;
Feevale College Application, Brazil
pgraziola@gmail.com

Abstract: The present paper is part of the symposium entitled "The docent development and teaching practice in the digital culture". Concerning Education, traditional teaching and learning theories are insufficient to help us understand how subjects are developed in a highly technological world, and it favors the appearing of new theories and methodologies that provide teaching and learning with the use of different digital technological means to promote human development. With this, there is an increasing need of people's mobility, of access and information exchange in any time and space, of ideas, experiences and knowledge sharing besides the necessity to amplify the traditional spaces of formal education, favor the use of the emergent mobile learning (m-learning), supported by the use of wireless mobile technologies (WMTs), such as Personal Digital Assistant (PDAs), palmtops, smart phones, cell phones, among others. It is in this context that a appears the problem that was the starting point to this research, in which I was willing to "investigate how the WMTs can contribute to the teaching practices in a dialogical, collaborative and cooperative perspective". The methodology that was used to the development of the research was the study case – understanding the teaching practices with the use of the WMTs in the mobile-learning context. So, from the analysis of two teaching practice situations with WMTs, the first with the Information Systems Group of the University of the Rio dos Sinos Valley, using direct observation and the second one with a group of secretariat of Human Sciences Department, of the same university, using the teaching practice application, it was possible to reach the following results: ergonomic and technological challenges, besides time and space factor, can affect or restrict the use of the WMTs in teaching practices; WMTs possibilities can offer spaces that allow a possible hospitality (adaptation) of these technologies by the subjects; the importance of a teaching mediation, in a dialogical perspective between teacher and student, in which the teacher has the orientation role, taking the interactions' mediations between student-information-device-student; the need for a flexible and open planning that adjusts itself and respects the context of the subjects involved with this process; the influence of these WMTs on the subjects' daily practices, as possibilities to revision and reconfiguration of their practices; the importance of the teaching and learning issues relating to the technological ones, giving the subjects' sensations, impressions, desires, affections and subjectivities a special value. This way, the investigation is an invitation to reflection on the WMTs and their educational potential, without presenting passing measurements, immediate working solutions that show the machine as the learning process center. The proposal is based on the subject-technology-subject interaction, that makes the democratic process of knowledge production in different areas possible.

Keywords: mobile learning. wireless mobile technologies. pedagogical practices. teaching. learning.

INTRODUCTION

The changes in social and educational context, caused by constant technological and scientific advances and the demands of the labor market by people more qualified and able to learn and solve problems cooperatively are increasing. Furthermore, the exponential growth of information and great proliferation of these have resulted in the rapid outdated parameters of knowledge, which requires constant updating. Thus, as Silverman (1995), learning becomes an activity for life, and the subject needs to develop skills of "learning to learn" and "learn cooperatively", so that the learning process is effective.

Few educational institutions have been able to experience innovative practices. These practices may expand the space beyond the formal classroom, to minimize the barriers imposed by time and space, helping in the expansion of teaching and learning and creating learning communities. But how to create conditions for this to occur? What Digital Technologies (DTs) can help you better enjoy the time we have? How to provide pedagogical practices beyond the formal context? Wireless Mobile Technologies (WMTs), combined with methodologies appropriate to the nature of that environment may represent an opportunity to answer these questions?

The potential of WMTs must be understood and evaluated to enhance and improve teaching practices and, consequently, the processes of teaching and learning.

By analyzing the interactions of the subjects who participated in the study sought to understand how they relate and what the specifics of the processes developed. Also, the ways in which the subjects achieved the results, and the manner in which they expressed different types of interactions between the interlocutors of the learning process via m-learning.

New technological means, in this case, the WMTs, alone do not constitute innovations in the teaching and learning, to the extent that innovation involves overcoming paradigms. This understanding has inhabited the minds of teachers / researchers who appropriate technologies, using them critically, reflecting on what they represent in the context of human development, organizations and societies, shifting the misconception that technology is the innovation, understanding it as driving the emergence of innovations, which arise in knowledge, so in live and live.

In this article, it becomes an object the teaching practice using WMTs in the context of mobile learning and the implications in the teaching and learning, a unit of research analysis.

First, it held a contextualization of mobile learning (m-learning), after, describes the methodology used, the characteristics of the cases, followed by data analysis and findings and, finally, the final considerations and future work.

MOBILE LEARNING (M-LEARNING)

The growing need for mobility of people, access and exchange information at any time and place, sharing ideas, experiences and knowledge, and the need to enlarge the area of formal education, nurture the use of emerging mobile learning (m-learning).

The mobile learning (m-learning) is made possible through the development and implementation of WMTs, which are portable computing devices such as PDAs (Personal Digital Assistants), palmtops, laptops, smartphones, among others, that use wireless networks. The use of WMTs, allied to interact with human actors geographically distant and physically, can provide occurring processes of teaching and learning.

From the technological point of view, according to Meirelles et al. (2004, p. 4):

> [...] two categories of end systems are beginning to gain popularity worldwide. The oldest is represented by the PDAs, with an estimate in Brazil of approximately two million users. The second category is represented by so-called smartphones, that besides the good features of PDAs, they allow voice communication, web browsing, available on some models Bluetooth and WiFi connections.

Meirelles et al. (2004, p.5) complements,

> since the resources for transmission infrastructure, the existing mobile communication networks become available, new challenges and needs arise, considering the study of computational resources of portable devices such as, for example, applications for PDAs enshrined in environments dominated computing so-called desktop computers offer users the possibility of conversion and handling of information in multimedia format.

Learning management systems open source may have expanded their functionality, supporting new applications to migrate to PDAs communication tools (Email, Forum, Diary), plus routines for data synchronization with the server. Thus, both the work offline as online work may be made without restriction of time and geographical space.

To Reinhard et al. (2007, p. 1),

> mobile learning is not a new idea - the chance to learn anywhere and anytime was always sought and empowered with tools such as books, notebooks and other mobile systems (laptops) that have existed for a long time. What happens today is that the WMTs can contribute to mobility by learning to

make available to the citizens quick access to a large and diverse amount of information, allowing your sending and receiving (when connected to Internet) and, furthermore, these technologies promote communication and interaction among people far removed geographically and temporally, in an unprecedented way.

Marçal et al. (2005, p. 3) state that,

> [...] the m-learning emerges as an important alternative education and distance training, which can be highlighted the following objectives:
> - the resources to improve student learning, which may have a computing device for performing tasks, annotation of ideas, information consultation via the Internet, record of events through digital camera, sound recording and other features exist;
> - provide access to educational content anywhere, anytime, according to the connectivity of the device;
> - increase the opportunities for access to content, enhancing and encouraging the use of the services provided by the institution, educational or business;
> - expand the number of teachers and learning strategies available through new technologies that support both the formal and the informal learning;
> - expanding the boundaries within and outside the classroom or the company, so ubiquitous;
> - provide a means for developing innovative methods of teaching and training using the new computing capabilities and mobility.

Already Saccol and Reinhard (2005) comment that the use of WMTs can bring many advantages, but every advantage possible counterpoints analyzed must consider, for example: is it possible for users of the technology spend more time on the field and less time on task "backstage "at the office or work in certain" dead time ", although the technical and ergonomic WMTs and proper context of mobile working can sometimes impose restrictions on it, you can find people and be located more quickly and frequently, so how to exchange data more quickly and easily, in different places and times, which contributes to the processes of decision making - an overload on the other hand, often generated by the easy replication of data, increases considerably.
The following is a description of the methodology.

METHODOLOGY

The nature of the research was based on a qualitative and exploratory approach. We chose to use the method of "case study" for the best fit to the research. The case study is a research strategy that contributes to the research object in relation to its context. Thus, the case study served as a methodological approach and research participant served as a mode of interaction between subjects, specifically in the second case. Streck and Brandão (2006, p. 52) state that "research participant delivery of a dual recognition of trust in my 'other', that I seek to transform the 'object of my research' in 'co-subject' of our research".
The first case study refers to the training process consists of a workshop called "Wireless and Mobile Technologies: The new paradigm of ubiquity and their application possibilities, " developed with a team of employees of GSI (Management Information Systems) of UNISINOS. In all, thirteen employees of GSI.
The second case study corresponds to a thematic workshop developed with a team of SCH (Secretariat of Social Sciences) of UNISINOS. This second case study as a research participant, as quoted above and refers to the development and analysis of teaching practice with the use of perspective WMTs dialogical, collaborative and cooperative (JUNIOR Grazioli, 2009). In all, twelve employees of SCH.
The relevance of the selected cases is the fact that the pedagogical practices developed with different groups of individuals who act not fixed:, mobile workers, whose interaction is strained by the introduction of a new element in the case linked to WMTs.
For empirical research, we used a prototype, the Virtual Learning Environment with Mobility (AVAM) called COMTEXT, modeled and built in the context of interdisciplinary research "Mobile learning in the organizational context"125. In both trainings were used the following materials / tools: observation, diary, email, chat, forum, skype, questionnaires.

---

[125] Part of the team: Prof. Dr. Nicolau Reinhard - FEA / USP (reinhard@usp.br) - Coordinator, Prof. Dr. Amarolinda Zanela Saccol - UNISINOS (aczanela@unisinos.br), Prof. Dr. Eliane Schlemmer - UNISINOS (elianes@unisinos.br), and Prof. Dr. Jorge Luis V. Barbosa - UNISINOS (jbarbosa@unisinos.br) and Prof. Dr. Steinar Krisoffersen - Østfold University College - Norway - (steinkri@ifi.uio.no). Figure 1: Prototype COMTEXT (Environment Competence in Context) - Main Module and Learning Module, respectively

From the viewpoint of the development team of the project, so that the m-learning can offer new opportunities for learning in a context of mobility, is necessary to fundamentally rethink the educational paradigms, conceptions of learning and teaching practices developed. Currently, a significant number of individuals-workers pass by many educational experiences and find that they often are incipient and do not meet their learning needs. It is believed that a model that is based on an epistemological interactionist-constructivist-systemic can account to help subject workers develop skills to act in a context of mobility (Graziola Junior, 2009).

Thus, the development of COMTEXT is based on epistemological interactionist-constructivist-systemic, in which the subject in a process of interaction with the physical and social environment, build knowledge, understanding the process of knowledge is understood as an integrated whole whose properties have their origin in the fundamental relations between its parts. Composed of subsystems that are interrelated forming a network in which these are interrelated and interdependent, so that the whole is greater than the sum of its parts, because the parties involved and ultimately the relationships between them.

The following are the characteristics of the two cases that were part of this research.

Features of the Workshop and Thematic Workshop

Both sklls were developed in the context of mobile learning through the use of HP iPAQs Pocket PC 4700 and the environment COMTEXT.

The Workshop "Wireless and Mobile Technologies: The new paradigm of ubiquity and its possible applications" aimed to promote understanding and discussion of the ubiquity of the new paradigm and its applications to UNISINOS. The choice was, due to be mobile workers, ie, exercising their professional activities in different physical points of UNISINOS and use technology every day, since acting managing the entire information system of the University. Thus, besides acquiring knowledge on the theme of the workshop could help in testing the prototype COMTEXT, thereby assisting in improvements and adjustments for subsequent practices.

The workshop lasted two weeks, totaling 15 hours, two physicists face meetings of 1 hour and 30 minutes (a date of opening and closing the other) and others, totaling 12 hours, conducted in person digital virtual (online). In the digital virtual face meetings, which occurred in a total of eight days, activities were guided by questions-axis (topics of study / discussion), one topic per day worked.

As a final practical activity, which would be part of the evaluation of the workshop was the drafting of a proposed project (hypothetical) groups in considering possible applications of these technologies for wireless and mobile activities of UNISINOS.

From the first case (Workshop), some questions have served as evidence to support the development of the Thematic Workshop.

The thematic workshop entitled "Dialogue, Cooperation and Collaboration in the context of collective work" aimed to promote understanding of the concepts of dialogue, collaboration and cooperation and its importance for the development of joint activities that require teamwork, through practical experiences Collaborative teaching with learning in the context of mobility.

The activities were conducted in b-learning mode, a total of 30 hours when we had some physical face meetings (1:30 in length - two per week) and other digital virtual classroom (the rest of the hours worked) using the Environment COMTEXT.

During teaching practice, it was proposed the development of a learning project (FAGUNDES et al., 1999) whose theme emerged a consensus as individual and group needs, and that was part of their professional contexts, culminating in a subsequent application in practice day-to-day. To develop the design of learning should find partners (among colleagues), as shared interests and curiosities about the problem to be solved. Thus, participants first made a survey of their doubts and their temporary provisional certainties about the problem that generated the project.

DATA ANALYSIS AND FINDINGS

The use of mobility in the teaching and learning necessarily imply an effective pedagogical mediation, in which the teacher has the role of advisor, problem-solving. To him it is provoking discussion of the subject's participation, it should monitor and analyze the construction of knowledge through interaction held in the spaces provided the environment in case the environment COMTEXT.

We observed a similarity in relation to how the mediation was developed for teachers, counselors, because in both cases, the subjects of GSI, which we used in virtually every encounter chat tool, and the subject of SCH, which we used in the tool forum meetings, which was revealed as a pedagogical mediation to three different aspects (regarding the contents in relation to subjects' participation and organization in relation to the process), but linked, they approach that (Rios, 2002) puts it, by stating that the goal of the teacher today is precisely to overcome the fragmentation of knowledge, communication and relationships through a dialogue or a partnership. Thus, within this perspective, the role of the teacher-coach should not be limited to providing information to students, but take the mediation of interactions between student-student-info-device, so that dialogue between teacher and students, enabling the construction knowledge in a challenging environment.

In the process of pedagogical mediation was evidenced also by the subjects of SCH, the availability and dynamics used by the teacher-adviser, to establish a relationship between the didactic teacher-adviser and its commitment towards the Thematic Workshop and the importance of pedagogical mediation, to create a pleasant and healthy climate that would enable the learning process. The evidence they approach (Freire, 1987) posits that when the teacher is no longer the only educates, but that while education is taught in dialogue with the learner, to be polite, well educated. Both thus become subjects of the process in which they grow together and that "arguments from authority" has no value. Freire and Shor (2006) further complement the dialogue that seals the act of learning, which is never individual, although an individual dimension.

Regarding the subject of reflection on their learning process in the context of the use of WMTs, the subjects of SCH when asked whether the way the training was developed using the COMTEXT contributed to a more meaningful learning, linked to learning practices and pedagogical mediation processes adopted by the teacher-adviser, so once again assuming the teacher-student relationship of dialogue and reflection in relation to daily work. The answers are approaching the far Estable et al. (2003), noted that for learning to occur, you need an exchange process with the other. Cooperative learning based on computer should be an educational strategy in which two or more individuals construct their knowledge through discussions, dialogue, reflection and decision making. For this process to occur, teachers and students should also be willing to collaborate, construct knowledge together, have common objectives.

These records also emphasize the importance of teacher-student relationship in teaching practice, approaching a pedagogical dialogue, which, according to Fernandes (2006, p. 376) puts it, refers to a "practice characterized by learning with their teacher students. These, through dialogue, they also learn that the commitment of the partnership is a fundamental human relationship in horizontal, the teacher does not exclude the responsibility of directing the process of teaching and learning, nor exempt the student's responsibility to push the boundaries of their practice, recreating the space-time of reflection and democratic relations in culture and ethics. "So when there is a commitment of partnership in teacher-student relationship, permeated by a constant dialogue in a democratic relationship and ethics, at the time of teaching practice, allows the creation of spaces where the subject can reflect on their thinking and about their learning process.

Regarding perceptions of the subjects of GSI and the SCH on the implications of the use of mobility in the teaching and learning. The subjects of GSI showed that implies: the need to learn to use the equipment

(hardware and software) to think about the provision of services for students, and some implications also indicate that the motivation for research and collaboration. Marcal et al. (2007) as a place of learning objectives with mobility, increasing the possibility of access to content, enhancing and encouraging the use of the services provided by the institution, educational or business. In addition, the cooperative environment should be focused on learning the subject and allow it to become an active agent that (re) construct their knowledge through interaction with the object of knowledge, be it social or physical environment. Thus, the WMTs (the environment COMTEXT in particular) become tools that can chance the interaction between subject and technology.

For subjects of SCH, implies: many new learning, the possibility of effective interaction, dialogue and exchanges, learning to organize and manage your time and involves commitment and reflection. It is evident that the perceptions of (GSI and SCH) will meet the proposals of its capabilities, making relations with its implications on the one hand that the workshop was aimed at, understanding and discussion of WMT and their possible applications for UNISINOS Furthermore the Thematic Workshop which aimed to promote understanding of the concepts of dialogue, collaboration and cooperation and its importance for the development of joint activities that require teamwork, through the experiences of collaborative pedagogical practices in the context of the learning disabled.

CONSIDERATIONS AND FUTURE WORK

From the analysis of data and findings, here are some thoughts and possibilities of using WMTs in the teaching and learning, a unit of research analysis.

Enable the creation of environments that enable the learner to continue learning, even outside the institution / place of formal education and / or in the context of mobility.

Be an open planning, flexible, ie, a dynamic that fundamentally respects and fits the context of the subjects involved in this process, because when used the WMTs, within their daily practice, these are limited to the area of daily work (physical) and the question "time."

Provide opportunities for reflection, through the knowledge built (the learning) of the subject, individually and through interaction and dialogue with peers and the teacher-adviser, the collective, beyond the reflection of the influence of these subjects WMTs in their daily practices, to thereby reconfigure and revise their practices.

Provide activities giving special value to the sensations, subjective impressions, desires and emotions of the subjects, intertwined in the educational process, not forgetting the goals of their use, particularly in the context of mobility, due to technical restrictions and ergonomic mobile devices, not forgetting to prevail didactic pedagogical issues regarding technology issues.

Devise ways to better adapt its use to the context of the subject, not to end up limiting the participation by individuals and their own adaptation of these technologies.

Encourage meetings (either face-physical or online) as areas of support and "meeting", mainly to solve doubts, questions and exchanges.

Thinking about the pedagogical mediation, a dialogical perspective between student and teacher, in which the teacher has the role of advisor, problem-solving, not merely the teacher's role to only provide information, but assuming the mediation of interactions between student-student-info-device .

Consider the use of learning projects that can set up as a possibility of teaching practice that instigates the action, the individual interaction, mediated by the teacher-adviser, contributing to the formation of autonomous subjects, reflective, and high level of ownership and still provide cooperation processes.

Understand how technological and ergonomic challenges, time and space, can affect or restrict its use in teaching practices in the context of mobility.

Have the "time" factor as a marker because it is not enough to provide access to content anywhere and anytime, but to provide a space and time for the subjects to read, study, act, interact and ultimately build knowledge.

Being attentive to the context of each subject, not forgetting the constraints of "dead time" (leisure) and its duality, because on one hand it is interesting to use these "dead time" on the other, can bring a number of risks, as an example, an overload of information and informational control.

Do not forget the factor of "physical space (context)" that can somehow "limited" mobility, the effective use of it, mainly due to technological restrictions to access the network at several points.

Enable the "effective" use of mobility, which can expand beyond the limits of the practices can also provide other possibilities, such as location and formation of affinity groups as subjects, notes of observations on field trips, among others.

Thus, this research consisted of an area of experience and call for reflection on the use of WMTs education without showing off and temporary measures, immediate solutions to work indicate that the machine as the center of the learning process. The proposal was focused on the interaction subject-subject-technology, which enables the production of knowledge democratically in different areas of knowledge. In this article we attempted to observe the potential motivated by the interaction of individuals with this technology.

As further possibilities, it was pointed out some questions that can guide future research: What are the possibilities to work in a mobile unlimited network access and mobility, for example, with access to the 3G network? As the subjects could perform field trips with mobile devices? How does this contribute to the teaching and learning of the subject? What are the possibilities for finding work in groups of interest, according to their previously saved profile settings? What are the possibilities of using other devices, such as the iPhone, which allows more features than offered by PDAs?

355 - Immersive Learning: a Current Future for Graduate and Postgraduate Programmes

Eliane Schlemmer[1] and Daniel de Queiroz Lopes[2]

Postgraduate Programme in Education – University UNISINOS, Brazil
[1]elianes@unisinos.br, [2]danielql@unisinos.br

Abstract: The present paper is part of the symposium entitled 'The docent development and teaching practice in the digital culture' and in this context it provides and discusses some research results the Digital Education Research Group (Gpe-dU UNISINOS/CNPq) has made. This group follows the research line called 'Educação, Desenvolvimento e Tecnologias' (Education, Development and Technologies) in the Postgraduate Programme in Education. Research pieces to be presented are in tune with 3D Web use, particularly metaverse entitled Second Life, as a technology enabling development of the Immersive Learning in the first years of formation of pedagogy teachers and teachers-as-researchers associated to the Postgraduate Programme in Education at UNISINOS.

Keywords: digital technology, Immersive Learning, formation, pedagogic practices, digital culture

3D WEB: USING METAVERSE FOR IMMERSIVE LEARNING… 'A CURRENT FUTURE'

3D Web technologies emerge with multiple possibilities enabling subject to act and interact in networked 3D graphics environments such as: (1) metaverses (Active World, Second Life, OpenSimulator, Wonderland), which allow creation and co-creation of 3D Digital-Virtual Worlds (MDV3Ds) where the avatar-represented subject may live and live with other subjects (avatars) e-living in these worlds; (2) Massive Multiplayer Online Role-Play-Games (MMORPGs), which enable the subjects as characters to make strategies to solve problems in 3D graphics environments; (3) enhanced reality; (4) mixed reality, and (5) Digital-Virtual Living Spaces (ECODIs)[126], which are a kind of digital hybridism where interaction, an aspect that stirs the living with, is not only textual (as we traditionally observe with other technologies), but rather in oral, gestural and graphical ways. These 3D Web technologies have contributed to the emergence of what has been called Immersive Learning (i-Learning).

In addition to co-creating networked 3D dynamic environments (MDV3D), avatar subjects may live their immersive experiences in their 'digital-virtual bodies' that are 'materialised' in the 'digital-virtual presence' in Metaverse technologies. But which immersion are we talking about? This avatar can 'see', 'feel' the environment and other avatars, and act and interact in different kinds of (textual, oral, gestural and graphic) communication that significantly enhances the social presence, allowing more involvement, vividness and immersion, and a feeling of belonging and (digital-virtual) presence, of 'reality', which is more intense than current technologies providing distance education, which grows the process richer and more significant from the viewpoint of living in learning (learning experiences).

Thus, these novel possibilities emerging with 3D Web technologies have aroused deep discussion and reflection about presence and distance concepts, making researchers rethink the use of the term 'Distance Education' to name learning experience with these technologies just because they understand that this traditional naming does not represent what learning subjects truly perceive in these spaces.

---

[126] The term ECODI was first used by Schlemmer in 2006 in the context of GPe-dU UNISINOS/CNPq, but it has been shaped during its theoretical ripening, emerging from research since 1998 about the use of different TDVs in teaching and learning process, from an interactionist/constructivist/systemic perspective taking technologies as empowering social cognitive and affective development. Thus the term ECODI represents a synthesis of theoretical constructions and establishment of relations and articulations from result for different researches the last 10 years. For SCHLEMMER et al. (2006, p. 8); SCHLEMMER (2008, p. 24); SCHLEMMER (2009, p. 143), an ECODI includes: * different integrated Digital Technologies (TDs) such as: Virtual Learning Environments (VLEs), 3D Digital Virtual Worlds (3D-DVW where interaction occurs among avatar-represented subjects, 'virtual humans' or bots), Web 2.0 technologies, communicative agents (interaction-created and programmed ACs), among others, which together favour different ways of communication (textual, oral, graphics and gestural), gathering every language in only one interactive space; * communication and interaction flow among subjects present in this space and; * interaction flow between subjects and the environment, that is, the very technological space. An ECODI fundamentally presupposes a kind of interaction allowing subjects (according to their ontogeny) 'living' in this space to shape it in a particular collaborative cooperative way, that is through his/her living and living together.

'Entering', acting, interacting, that is, living and living with in 3D dynamic environment as an avatar, is a significantly different way to go to a Webpage, website, AVA, Web 2.0 technologies, or even a 2D graphics environment. But what can this represent in terms of cognition and subjects' social cognition? How do they live, live with and learn in these spaces?

These are some of the issues the research group called Digital Education (GP e-du UNISINOS/CNPq) is recently concerned about, making distinct research pieces and producing some theorisations emerging in the context of teacher formation and training courses (Maturana & Rezepka, 2000) in i-Learning in graduate and (Stricto sensu) postgraduate courses.

Thus we can say that the phrase 'a current future' in this paper title is associated to the ongoing innovations linked to the presence concept in the sense of 'being current', providing a social presence when we use different digital technologies (TDs). In this sense, it represents some of the movements introduced in Digital Education, which will make up the process of construction of novel educational realities together with other initiatives.

FORMATION AND PEDAGOGIC PRACTICE IN DIGITAL CULTURE

How are different Digital Technologies (TDs) present in teacher formation? How are they understood in the pedagogic practice? Are they understood as a tool, instrument or support for which they are necessary to be adapted, incorporating them to pedagogic practices, or as an object to think with/about teaching and learning processes, as technologies to introduce space for communication, interaction, collective construction, learning, becoming real living spaces to bring about human (cognitive, affective, or social) development?

Many of the current TDs are not part of teacher training processes, are not in graduate and postgraduate programme curriculums, and when they are current, they usually are understood as another recourse, another way to grow education more attractive for younger students, they are a tool, a support that allows changing old pedagogic practices. In this case, the novelty representing the use of different TDs in education, which in turn enables innovation, ends up leading to no significant change in education.

But why does this mistake linger? One of its hypotheses is that it is difficult to use particular TDs, linking the lack of usage of these technologies with the lack of particular technical and pedagogical skills for education use, which points to the need to empower digital citizens.

> We understand 'Empowering, Citizen Digital Education' as such a level of appropriation, digital technological fluency, to enable the subject to be a contemporary citizen, empowering him/her to have social autonomy and creative authorship in a dialogic and cooperative space cut through by mutual respect and internal solidarity. This means to create spaces in which the other is recognised as a genuine other in interaction and so someone with whom one can have a relationship in which both are co-teachers and co-learners in different moments in a process of multiple relational pedagogical mediation and intermediation. This would unleash subjects from oppressive relationships in a space where everyone mutually change in interactions leading to the authentic dialog in the digital-virtual living and living with (Schlemmer, 2010, p. 10).

We need not only to perform digital inclusion, but rather create systems of formation, processes of participative training courses that effectively may help to develop citizen autonomy in digital environment. It is in this context that we have used the term digital citizen empowerment, going further than the concept of digital inclusion. Gilson Scwartz[127], founder of the project 'Cidade do Conhecimento' at USP, has maintained that 'the question is not to include in the digital [environment], but rather in knowledge, that is, in the digital social and cognitive networks'.

Thus, understanding the teacher's reality and helping him/her with technical pedagogies so that s/he may be digitally empowered and may suggest practices with different TDs to be innovation in the educational context, is what circulates in GPe-dU UNISINOS/CNPq works to be introduced below.

RESULTS FROM WORKS THE DIGITAL EDUCATION RESEARCH GROUP (GPE-DU UNISINOS/CNPQ) HAS DEVELOPED

In the scope of novel technological possibilities linked to the 3D Web, such as Metaverses, new challenges emerge for the teacher's formation and practices, which led to the early research works in 1998 with the metaverse Active Worlds. In 2005 GPe-du UNISINOS/CNPq, research group associated to the research line

---

[127] (*Interview with Gilson Schwartz for the magazine TIC Educação - May 2007 – in http://cathy.spaceblog.com.br/19415/Emancipacao-digital-nosso-maior-desafio/*).

called 'Educação, Desenvolvimento e Tecnologias' in the Postgraduate Programme in Education, started also to investigate strengths and limits in using the metaverse technology Second Life in education, and in 2006 it created the island UNISINOS (figure 1).

Figure 1: Island UNISINOS in metaverse Second Life
(Community Centre and GPe-dU)

Thus since 2006 UNISINOS University maintains the UNISINOS, an island that was founded in education research aiming at providing space for developing research that allow understanding limits and strengths in using this technology (individually and in the context of digital technological hybridism) in the processes of online teaching and learning, as a way to boost subjects' social cognitive development, and novel ways of social organisation and growth possible to emerge in these spaces.

Every space built in Island UNISINOS are developed by graduate students (scholarship holders for scientific skills, master and doctoral students in education, who are members of GPe-dU, which has been designed for promoting interdisciplinarity involving disciplines such as pedagogy, psychology, digital games, computer science, philosophy, right, physics, etc.).

It was thus, by the students' initiative, that GPe-dU has won a representation on the island UNISINOS, becoming the earlier research group in education in Brazil to 'enter' Second Life. It is in this represented space that members meet to make collaborative research, discussions and works in group, develop training processes, organise events, do workshops, presentation of final papers, master's dissertations, doctoral theses, and meetings. Thus, graduate and postgraduate students in education appropriate that space.

On the island UNISINOS many graduate (ECODI UNISINOS VIRTUAL) and postgraduate (ECODI PPGs) projects of research and development are conducted.

PRE-SERVICE TEACHER EDUCATION IN THE COURSE OF PEDAGOGY: THE PROJECT ECODI UNISINOS VIRTUAL

The project ECODI UNISINOS VIRTUAL is a partnership between GPe-dU and the Graduate Unity at UNISINOS, particularly EaD UNISINOS. It aims at developing a Digital-Virtual Living Space to offer online graduate education. This 3D-represented space, that is, a space represented by its illustrations and possibilities involving the construction of 3D learning objects, simulations, games, etc., seeks to stir development of methodological propositions to promote teaching and learning processes based on a systemic interactionist/constructivist epistemological conception to provide innovation in pedagogical practices. The objective is that it becomes a living space that may favour knowledge construction in a collaborative and cooperative way and stir learning (that may involve curiosity, problematisation, exploration, experimentation, and research) for subjects participating in it.

One of the main objectives for GPe-dU UNISINOS/CNPq with this partnership is constructing a participative formative research and development practice in 'Digital Education', chiefly in relation to i-Learning. This partnership involves teachers-as-researchers from different branches of knowledge at the university, master's and doctoral supervisors, scholarship holders for scientific skills, EaD UNISINOS staff, and students. It is an extra space for learning to help in the process of subjects' Digital Citizen Empowerment participating in it. We understand that this partnership may effectively help the development of a set of necessary skills for the contemporary teacher, who is in a society that is highly connected in networks, in which this generation moves easily and quickly with access to a huge variety of information and interaction possibilities. This generation, which has particular familiarity with all kinds of TDs and easily creates his/her own networks, 'thinks with' and 'through' these technologies, and today is part of our student public. This set of skills involves more than skills of the specific field of different branches of knowledge, but rather teacher training in their respective domains, digital skills linked to processes of teaching and learning.

Thus the project ECODI UNISINOS VIRTUAL was designed from three chief domains: the creation of the UNISINOS VIRTUAL space with general information; the initial formation (pedagogy and physics teacher course); creation of 3D spaces; and higher education teacher formation. Among the results found thus far we can mention the creation of the space UNISINOS VIRTUAL with general information, including the development of a Digital-Virtual Living Space for online graduate education (figure 2); the setting of two graduate Learning Programmes, one linked to the pedagogy course, and one linked to a degree in Physics. In this paper we will address only the pedagogy course.

Figure 2: ECODI UNISINOS VIRTUAL

PA, 'Teaching and Learning in the Digital World'

The pedagogy at UNISINOS is based on Learning Programmes (PAs). PAs are made of fields of problematisation of reality or skills necessary for the future teacher.

The PA 'Teaching and Learning in the Digital World', which is in this curriculum, is offered as a b-learning, in a context of digital technological hybridism, involving the virtual learning environment Moodle, Web 2.0 tools, and 3D Web technologies such as metaverse Second Life. This PA aims at creating spaces for digital learning and empowerment that may develop theoretical and methodological stance and technological knowledge to deal with different Digital-Virtual Technologies (TDVs) in knowledge construction. It seeks to reflect upon the use of these technologies for human and social development in pre-service, children's, and young and adult education.

The pedagogical practice used in this PA is based on the methodology of learning projects (Fagundes, Sato and Maçada, 1999), which Schlemmer (1999, 2001, 2002) adapted to higher education under the name 'Problem-Based Learning Project'.

One of the aspects distinguishing the 'Problem-Based Learning Project' from traditional methodologies is the focus on the subject learning in interaction with other subjects in the use of different integrated TDs. A problem-based learning project comes out of curiosity, doubts, individual and collective problematisations that give rise to themes to be researched, so that one can find elements that help solve the original problem. The project is constructed and developed in a collaborative and cooperative way based on mutual respect beginning with autonomy and authorship of subjects involved in the process.

> A project for learning will be created by conflicts and disturbances in this meaning system making up the learner's particular knowledge. How can we touch this system? The very student is not aware of it! Therefore, choosing the variables to be tested when seeking for the solution of any problem, must be held by the student's questions (Fagundes, Sato, & Maçada, 1999, p. 16).

Problem-based learning projects in the context of PA 'Teaching and Learning in the Digital World', begin with the creation of a Virtual Learning Community in the AVA Moodle, beginning with the thematic platform 'Digital Education'. Students list their provisional certainties and temporal doubts in discussions that may be in a presential physical context or in a digital-virtual context (using the forum or chat of the community created in the Moodle, instant messaging (MSN, SKype, GTalk), metaverse Second Life, etc., or

918

even in both. Then, sharing doubts, groups are formed, which gives rise to microcommunities. With the groups formed, one starts to plan the learning project and subjects list what they know about the problem and what they do not know and, therefore, they need to research, they describe the project objectives, how they will develop it, how they will collect data, what recourses and materials they will use, and how they will introduced it. The forum, blog, wiki, etc. may contribute for this organisation. There is no formal order or rule to be followed nor mainstream technology for structuring problem-based learning projects.

After this early phase of forming groups and planning the project, one needs to begin to search data to find elements that may help to solve temporary doubts and confirm or not provisional certainties concerning the problem to be investigated. In this context students make research and interviews using TDs such as Google Scholar, CAPES Dissertations and Theses, instant communication (MSN, Skype and GTalk), social networks, etc.

With data found and the use of different TDs allowing subjects' authorship, such as Web 2.0 tools (Wiki, PBWorks, blogs, eBlogger, etc.) and 3D Web technology (metaverse Second Life), the project starts to be built and the work runs the whole term in a collaborative and cooperative way between teacher and students. While the project is developed, the whole process of construction is available for all students in the class and the teacher to follow and contribute. Thus a truly collaborative and cooperative work is structured around different problems making up the subject 'Digital Education'.

In the term there are two specific moments for project presentation: first when subjects finalise the planning phase and second when they finish the project. Then a group examines de development of another group following some criteria the whole group defines and upon which projects were accompanied through all the term. Later every evaluated group restarts their project upon its evaluation to fix paths and do what was suggested at the evaluation.

In addition to the problem-based learning projects, other important activities make up the PA in the virtual learning community including all students such as forums, and weekly chats for discussing the theory that grounds the PA; learning diaries to register learning works, perceptions, doubts, difficulties and feelings towards them; weekly chats to solve doubts; the creation of a digital-virtual identity in Second Life and interaction on the island UNISINOS.

Thus PA 'Teaching and Learning in the Digital World' is based on a systemic interactionist/constructivist epistemological conception coming true by problematising methodologies such as problem-based learning challenges and projects. In this context, different digital technologies are used in an integrated way to open possibilities of understanding, making meanings towards how they can be used in teaching and learning.

The pilot project: PA Teaching and Learning in the Digital World in the project ECODI UNISINOS VIRTUAL

In the first term of 2010, in addition to the activities mentioned above, it was proposed a novel challenge: building a 3D digital-virtual space on the island UNISINOS to illustrate the understanding of some concepts. This challenge gave rise to the building of two 3D digital-virtual spaces representing different conceptions of school. One was represented by the 'Analogical Museum' and another one by the 'Pedagogical Cooperative' (names students gave). In the beginning, there was necessary a planning of spaces to be represented, involving making a list of concepts and research to find elements to build metaphors that would make up these spaces. The creation of these spaces was based on objects students built in the *Sandbox*, and objects from places giving freebie libraries.

The Analogical Museum was designed to represent the formal school with dark colours, students in cages, representing the locking of knowledge, the teacher as the only knowledge holder, lined up classes and old furniture.

The Pedagogical Cooperative was designed to represent the systemic interactionist/constructivist school, a colourful and joyful space with interactive panels for the visitor to create, browse through, contribute, solve doubts and giver suggestions. It is a type of school towards learning and knowledge building.

This space was developed weekly step by step in formal and informal meetings. The formal meetings were on every Friday in the morning (when data were collected) and then discussions and shared ideas occurred until the group agreed upon something to represent the imagery built by everyone (figure 3).
Figure 3: PA "Teaching and Learning in the Digital World" -ECODI UNISINOS VIRTUAL

This is an open student-built space that is not fully worked out, but rather represents so far built knowledge systematisations, small summaries, the conception in which this space is embedded. This space is also a challenge for future groups, who may continue the project, improving it, implementing it, giving it elements for knowledge building.

The project ECODI-PPGs UNISINOS: a proposal for training teachers-as-researchers
The project ECODI-PPGs UNISINOS concerns teaching and learning in Web computer environments in a context of digital technological hybridism. It focuses the creation of a Digital-Virtual Living Space – ECODI (SCHLEMMER (2006, 2008, 2009), SCHLEMMER et al. (2006, 2007)) to develop teaching practices and training processes for postgraduate teachers-as-researchers at UNISINOS. Research is based on the following problem: How the technology ECODI may maximise postgraduate teaching and learning processes? The chief objective is creating a space for information, interaction and research to develop teaching practices and teacher-as-researcher training processes in the postgraduate programme by using the ECODI.

The project ECODI-PPGs UNISINOS involves four domains: welcoming the project; PPG spaces; teacher-as-researcher training (including teachers, master and doctoral students); and continuing education (extension involving the community and master's and doctoral students and scholarship holders for scientific skills). The project is under work and thus far the following is occurring:

In the 'Welcoming the Project' a space for project presentation was created including information about the research project and spaces for general use for different PPGs such as Arena (figure 4)

Figure 4: space for welcoming the project ECODI PPGs UNISINOS

In 'PPG spaces' there are PPG representations in Education, Administration and Philosophy, and Communication and Applied Linguistics PPGs (figure 5) are under planning. In each representation general information is offered: PPG introduction, research lines, research summaries, selective process, publications, events, blogs, and other information every PPG may find important.

Figure 5: Representation of PPG spaces in Education, Philosophy and Administration

In teacher-as-researcher training, different activities have been developed: research group meetings, orientations, workshops, domestic and international events, PPG curricular offering in Education (seminars and directed reading), qualification and presentation of dissertations and theses, etc. (figure 6)

| GPe-dU Meeting | Orientation | Curricular offering - directed reading |
| Curricular offering – Seminar – Spaces built by Master's and Doctoral students | Workshop and Events | Qualification and presentation of dissertations and theses |

Figure 6. Education of teachers-as-researchers

In continuing education, many extension courses are developed. GPe-dU Master's and doctoral students and scholarship holders for scientific skills organised and developed them to show the research results and form teachers to make up the ECODI (figure 7).

Figure 7: Continuing education

In this context, some results have been achieved: creation of a space for information, interaction, and research, to develop teaching practices and Stricto Sensu postgraduate teacher-as-researcher training; the articulation between research, teaching (degree in Pedagogy by activities in the Learning Programme 'Teaching and Learning in the Digital World', as well as assisting graduation works, and scholarships for scientific skills; postgraduate programmes — course seminars and assistance for presenting doctoral theses and master's dissertations) and extension (extension courses for the educational community), production of pedagogical material to help teacher-as-researcher education, and scientific publishing in periodicals, events and books.

RESEARCH RESULTS: I-LEARNING MAXIMISATIONS AND LIMITS

When we have analysed data from these experiences, we have found some aspects that can be considered as empowering learning in these new contexts, which has led to deep discussions and reflections concerning technical pedagogical appropriation for online teaching.

The sense of being immerse in a third-dimensional space, with the avatar, makes subjects (teachers and students) have a more intense wish to learn, resulting in the extension of the time subjects devote to learning.

The pleasure of finding things out, the emotion of noting that learning is occurring, amplifies subjects' self-esteem.

The need to build something together in a space everyone was appropriating that stirred intense (textual, oral, gestural, and graphic) interaction, resulted in enhanced autonomy and authorship of subjects.

The pleasure of being the author/co-author of a world ('construction of our small PA island') nourishes and is nourished by enhanced autonomy, which grows wider at every new conquest.

The avatar-represented social presence empowers the socialisation of the achieved learning.

Awareness of the skill of built (or not built) concepts is favoured when subjects have to represent metaphorically these concepts.

The softening of the fear to make mistakes, touch something, and the perception that making mistakes, touching, is part of learning ('I learned a lot and I learned particularly not to be afraid of making mistakes, touching, that is, learning').

The avatar's social presence in a 3D immersive environment allows the enhancement of the sense of being safe in a context of online education.

It is important to be connected with other people and have a social presence in the interaction (enhancement of the sense of presence).

The reflection about learning enabled by the avatar's action causes the rupture with paradigms crystallised in the everyday living as a learner and enables the perception of the autonomy as empowering interaction and authorship, allowing the pleasure of finding things out, the freedom of learning by making new connections. ('Since the first class I allowed me to find new ways to interact and integrate the proposed activities (autonomy), and with satisfaction I have noted that my avatar has talents that were dormant in my 'analogical physical self': curiosity, courage to permit myself to click where I wanted to and so make connections I didn't imagine I could… I can say that Nynah (the avatar's name) helped me to admit I don't manage everything, but I can learn, I can dare, I can wonder trying to understand the universe around me and which I have learned to wish to belong to: the technological!')

In many experiences in the Immersive Learning, it was possible to check out the increasing student enthusiasm, in so far as findings and appropriation of new knowledge were occurring, which contributed to meaning making to learning practices. In this sense, we highlight the significance of methodologies and practices promoting interaction, growth of subjects' autonomy and authorship in a collaborative and cooperative context.

Immersion by The avatar's telepresence and digital-virtual presence in 3d environment enables the sense of presence, belonging and community life. The interaction in the i-learning context is much more significant, interesting and compelling, and the sense of belonging grows more and more intense. This showed to be critic for the online learning process. AVA users' saying such as 'I feel alone', 'I miss people', etc., evinces the significance of social presence for subjects interacting in these environments. Researchers have pointed up this issue as a successful factor for the student and a challenge for the current EaD.

In this process, we also identify some aspects that can be considered as limiting for learning in metaverse: some students' lack of digital technological skills; technological difficulties, particularly due to the graphic adapter low performance and internet speed, the latter at some moments causing initial difficulties in oral communication; the avatar's initial difficulties to move in this novel space, chiefly associated to the notion of space, direction; initial sense of 'being lost' in this space and having to count for too many novel simultaneous data.

It is worth noting that we are not defending the avatar interaction in 3D immersive environments, at the expense of subjects' interaction, with their physical bodies in natural environment, but rather we evince how the further can complement and empower the latter, that is, we understand that a context of hybridising the worlds may empower the subjects' learning.

DISCUSSIONS AND CONCLUSIONS

Now let's return to this paper title: 'Immersive Learning: a Current Future for Graduate and Postgraduate Programmes' and reflect upon the phrase 'a current future'.

Researchers in different continents have pointed 3D Web with its metaverses, MDV3Ds, MMORPGs, associated to mixed and enhanced reality, as a future internet, but we can notice that it is a current future because kids and teens are growing, living and living with in these new worlds, trying the simultaneity, the hybridism between worlds. So how should we think about education for this generation? How should be this teacher's training?

We know that different media enable the development of different skills (which encourages us further to think in the significance of coexistence of these media). So is it possible that 3D Web with the Immersive Learning is opening space for a novel world in Education, but what world is it? Where do we go to? Platforms like Active World, Second Life, OpenSimulator, OpenWonderland, and many others, are temporary, but 3D Web's concept, metaverse, MDV3D, Immersive Learning certainly are not, as they provide something very interesting, particularly for the education field: richer immersive and interactive experiences that may empower human education and training.

However, we have to understand the Immersive Learning not as a substitute for other possibilities in online educational environment, or physical presential education, but rather as a different, complementing possibility to coexist in relationships and interrelations in the educational context in contemporary society, in networks.

We need to consider that novelties emerging together with the different digital technologies such as Immersive Learning, Mobile Learning, Pervasive Learning, Ubiquitous Learning (or u-learning or ULearning) do not mean necessarily innovation in Education. However, they represent an effective possibility for fresh understanding of concepts like time, space, presence, distance, interaction, information, knowledge, leading to unbalance in the system of subject meaning, encouraging paradigm rupture and changing the way to develop particular processes.

We suggest teachers-as-researchers to appropriate these digital technological novelties to understand them in the context of their specific nature, and develop the digital technological and pedagogical skills necessary for their usage. Exactly this movement may cause digital empowerment for a better enhanced understanding of limits and strengths of each one in the educational context, which may help to provide innovation for methodologies, practices and pedagogical mediation. Otherwise, we can speak of a mere novelty, rather than innovation in education.

Therefore, observing trends like mixed and enhanced/augmented reality, creating avatars, playing MMORPGs, trying 3D Web in fixed and mobile networks, **attending meetings and events in different MDV3D**, integrating online research groups and communities, are useful initiatives when one wishes to know better this 'world' to identify its strengths and limits and, above all, approaching the digital culture, to which many students are members.

357 - The Potential of E-learning in ICT Training Teachers

Carla A. Martinho[1] and Paula Vaz Fernandes[2]

[1]*CAPP-ISCSP,* [2]*UAb, CAPP-ISCSP*

Abstract: This paper presents a case-study in both the areas of LLL and ongoing teacher training through e-learning in ICT. The training session "Introduction to Questionnaire and Treatment in Excel", which is the basis of this study, is aimed at primary and secondary school teachers and was organised by the Universidade Aberta (UAb) Science and Technology Department (DCeT). Excel is an integrated tool in the Office package, so it is accessible to everyone and can be used according to the needs of each one. The use of this package can serve multiple domains, is versatile and easy to use.

Both LLL and ongoing teacher training are strongly recommended in the European Union Memo (2000) and vastly used in classroom teaching in Portugal.

However, its usage in the e-learning process is rare. The UAb had a pioneer role in the diversified offer of LLL's in teachers' ongoing e-learning training by introducing in its 2006-2010 and 2010-2014 strategic plans lifelong training sessions as one of its main priorities. Nowadays, in Portugal, 90% of long-distance learning is promoted by the UAb.

The offer of distance training sessions by a state University is undoubtedly a guaranty of sustainability for the development of ongoing learning "for all". The distance learning, in particular UAb's Pedagogical Model offers: student´s centered learning, flexibility, interaction and digital inclusion.

This session was based on the UAb's Pedagogical Model using the MOODLE platform which is based on a type of distance learning through online mobility, in a virtual classroom environment. The virtual classroom is an organized space where both the contents and the didactic materials are made available, and where the following interactions (trainees-trainees; trainees-trainer; trainer-trainees) take place, with the aim to promote learning.

Asynchronous communication was privileged with an emphasis for discussion forums, whilst having in mind, readings, platform access, files download, possible research, individual thoughts, and participation in both group and final assessment assignment.

This training session was set up in its totality as e-learning and organised over four weeks, combining a total number of 26 hours of individual and group work. It was divided in five modules, numbered from 0 to 4. In the first week the first two modules took place: the first module named module 0 consisted in the adjustment to both the Moodle platform and the virtual classroom model; the second module named module 1 focused on the characteristics of asynchronous collaborative work, allowing the trainee to better understand what it means to be an online student.

The trainees that took part in this training session, the majority were female. The ages of all trainees ranged from 26 to 61 years old and more than half of the enrolled trainees had age upper 46 years old, showing evidence that older teachers seek further training in ICT.

The trainees were distributed in eight of the eighteen districts of mainland Portugal and the most often mentioned reason for participating in this training was the subject, flexibility and the acquisition of credits.

Keywords: ICT, e-learning, LLL.

INTRODUCTION

This paper presents a case-study in both the areas of LLL and ongoing teacher training through e-learning in ICT. The training session "Introduction to Questionnaire and Treatment in Excel", which is the basis of this study, is aimed at primary and secondary school teachers and was organised by the Universidade Aberta (UAb) Science and Technology Department (DCeT). Excel is an integrated tool in the Office package, so it is accessible to everyone and can be used according to the needs of each one. The use of this package can serve multiple domains, is versatile and easy to use.

Both LLL and ongoing teacher training are strongly recommended in the European Union Memo (2000) and vastly used in classroom teaching in Portugal. This memo emphasizes "The effective use of ICT will make a significant contribution to implementing lifelong learning by widening access and introducing more varied ways to learn, including through ICT-networked local learning centres open to a wide range of people of all ages.

However, its usage in the e-learning process is rare. The UAb had a pioneer role in the diversified offer of LLL's in teachers' ongoing e-learning training by introducing in its 2006-2010 and 2010-2014 strategic plans lifelong training sessions as one of its main priorities. Nowadays, in Portugal, 90% of long-distance learning is promoted by the UAb (Hassan and Laaser, 2010).

The offer of distance training sessions by a state University is undoubtedly a guaranty of sustainability for the development of ongoing learning "for all". The distance learning, in particular UAb's Pedagogical Model (Pereira *et al.*, 2007) offers: student´s centered learning, flexibility, interaction and digital inclusion (Pereira *et al.*, 2009).

This session was based on the UAb's Pedagogical Model using the MOODLE platform which is based on a type of distance learning through online mobility, in a virtual classroom environment. The virtual classroom is an organized space where both the contents and the didactic materials are made available, and where the following interactions (trainees-trainees; trainees-trainer; trainer-trainees) take place, with the aim to promote learning.

Asynchronous communication was privileged with an emphasis for discussion forums, whilst having in mind, readings, platform access, files download, possible research, individual thoughts, and participation in both group and final assessment assignment.

COURSE'S GENERAL ORGANISATION AND ITS INSTITUTIONAL SETTING

The training session "Introduction to Questionnaire and Treatment in Excel", was an initiative of the ongoing training programme for teachers of Mathematics in the DCeT, directed at primary and secondary teachers of the Portuguese school system. This session, just like all the other sessions offered by the UAb in this area, is accredited by the Scientific-Pedagogical Council of Ongoing Training / Ministry of Education and allows teachers who complete them successfully to obtain credits in order to progress in their careers.

This training session was set up in its totality as e-learning and organised over four weeks, combining a total number of 26 hours of individual and group work. It was divided in five modules, numbered from 0 to 4. In the first week the first two modules took place: the first module named module 0 consisted in the adjustment to both the Moodle platform and the virtual classroom model; the second module named module 1 focused on the characteristics of asynchronous collaborative work, allowing the trainee to better understand what it means to be an online student. The remaining modules addressed technical questions related to the training. The various modules were devised according to a chronological sequence. For each module the trainer defined a number of activities to be developed, partially or totally by the trainees, as stated in the learning contract. This document is presented at the beginning of the course and contains all the relevant information, namely, training objectives, competences, methodology, resources, environment, sequence, assessment, calendar: week 1, week 2, week 3, week 4.

Chronological Sequence of the Session and Competences to Attain

The chronological sequence of the modules, its identification and each of the competences to attain, are summed up below in Table 1.

Table1: Chronology, identification and competences of the session "Introduction to Questionnaire and Treatment in Excel"

Week	Module Identification	Skills
1st	**Module 0 -**Familiarity with the online environment **Module 1** - Work online as a team	Know and use Moodle as a resource for teaching and learning; Enable the interaction with the class, participating and setting out ideas and arguments in a clear and succinct way; Acquisition of knowledge about being a student online.
2nd	**Module 2 -** Introduction to the Questionnaire	Know and characterise a questionnaire; Enable to elaborate a questionnaire: distinguishing types of questions and response scales; Knowing the sampling techniques commonly used in research by questionnaire.
3rd	**Module 3 -** Introduction to Analysis in Excel	To Know enter data from a questionnaire in an excel file; Organize and show results using Excel; Statistical functions.
4th	**Module 4 –** Dynamics tables and charts using Excel	Learn how to build different types of graphs that helps interpreting the results; Enable to use cross-references allowed by the use of Dynamics Tables.

TYPE OF ACTIVITIES AND SUPPORT MATERIALS

Different types of activities were proposed for each of the modules. In reality, during online classes, the trainees were encouraged to take on the role of learners and to develop the activities in which they were active subjects in the process, instead of being isolated and without interacting with the remaining group.

Activity 1, presentation in the virtual classroom / being an online student equipped trainees with the basic and essential elements for the development of the work in the virtual class. To that effect, queries forums on the working of the platform as well as the texts – "Online Student Guide", "How to participate in a discussion online" and "How to manage time" were made available. Furthermore, instructions were given on how to participate in an online discussion after a reflection on the above mentioned texts. In this first collaborative forum all 30 enrolled students participated at least once with a total of 62 contributions. The group of activities in this first week was not assessed as they were part of the introductory module.

Activity 2 consisted in group work and started with the individual reading of texts available in the virtual classroom on the topic "Introduction to the questionnaire". A team forum, to which only one member of each team had access, was organised in order to write up a report based on the available information on the following topics:

1. listing of the more important and accomplishable procedures in the making of a questionnaire by a beginner.
2. analysis and solution proposal of a group of questions which not always verified validity or reliability. This activity took place during the 2nd week of the course and had a total number of 486 contributions.

Activity 3 included in module 3. Adding data to an Excel questionnaire, had as tutoring supports and explanatory video prepared by the trainer whose aim was to have trainees experimenting with adding data to a spreadsheet. To that effect, a forum was created and named "Adding data" and counted with 25 contributions.

Activity 4, Creating dynamic tables was similar to activity 3 and supported by a database supplied by the trainer in an explanatory tutorial on dynamic tables, the 103 contributions shower a greater commitment of the trainees as a way to overcome the complexity of this area. Included in this number of contributions was the challenge set by the trainer which consisted in sharing the work produced individually in a specific forum, thus allowing each trainee to better improve his / her performance through the direct observation of other colleagues' work.

The last activity, final assignment, based on a questionnaire suggested by the trainer, allowed the creation of a specific database shared by the class. This database was the starting point to the analysis of the results when you create a questionnaire. The results of this analysis were presented in an individual report which had to include charts, tables and statistical measurements which would allow us to draw conclusions related to the starting questions and, as a result, had to be followed by their specific interpretations.

ASSESSMENT AND CLASSIFICATION

The assessment is based on two criteria – virtual classroom and discussion contributions, as well as, the final assignment.

The assessment of the discussion contributions is based on the following criteria: meaning/quality of the contributions; time/opportunity; frequency of the contributions; cooperation with colleagues.

The final assignment consisted in the creation of a small database in Excel and its statistical/graphic treatment using the functions mentioned during the training. The report was assessed having in mind the following factors: scientific correction; knowledge of the fundamental concepts applied in the assignment; knowledge of data handling in Excel: ability to critically analyse results, presentation of results and conclusions.

Classification was decided taking into account the following: contribution in the discussions, including collaborative activities: 30% and Individual final assignment: 70%.

Assessment was conducted according to the UAb pedagogical model which envisaged the completion of an individual final assignment. A qualitative and quantitative rating scheme was used according to the revised nº 3 of article 13 of the RJFCP, obtained by the trainee, according to the following marking scale which ranges between 1 and 10 marks: EXCELLENT: 9 to 10 marks; VERY GOOD: 8 to 8,9 marks; GOOD: 6,5 to 7,9 marks; SATISFACTORY: 5 to 6,4 marks; FAIL: 1 to 4,9 marks.

TRAINEE CHARACTERISATION

Out of the 30 trainees who took part in this training session, 90% were female and 10% male with ages ranging from 26 to 61 years old (chart 1), 50% of the enrolled trainees had ages ranging between 46 and 56 years old.

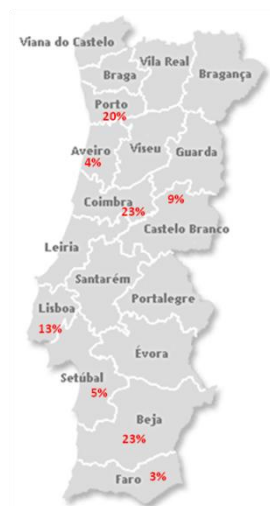
Chart 1: Age characterisation of the trainees

With regard to academic qualifications in this group of teachers, trainees, 90% had a degree, 7% a Master's degree and 3% a PHD (chart 2 A). Their training areas were very diverse, but the greatest number was of Maths teachers (chart 2 B)

Chart 2: Trainees characterisation regarding qualifications and teaching subjects

With regard to the levels at which these trainees were teaching was also very heterogeneous and there is a greater representation of teachers from secondary schools, 47%, followed by teachers teaching 2nd cycle, 23%, 3rd cycle, 20% and pre-school 10% . The absence of teachers attending the action of the 1st cycle was noted in this analysis.

Our trainees were distributed in eight of the eighteen districts of mainland Portugal, and its representation by districts as follows:

- Aveiro   4%
- Beja   23%
- C. Branco   9%
- Coimbra   23%
- Faro   3%
- Lisboa   13%
- Porto   20%
- Setúbal   10%


As shown in Figure 1.

Figure 1: Geographic distribution of trainees

Summary of the main evidence

The trainees were from various regions of Portugal. Mostly the group consisted of women, which is expected, since this is a training for teachers (in Portugal the majority of teachers are female). Most trainees were older than 46 years, showing evidence of being older teachers to seek further training in ICT.

The main motivation for attending this training is summarized in the data presented in the graphs belo

Chart 3 A: Motivation for attending the course

Chart 3 B: Motivation for attending the course by age

■ Flexibility ■ to obtain credits in order to progress in career ■ Subject

The motivation most often mentioned was the subject, 67%. Flexibility was the second choice, 23%, and only 10% indicated the acquisition of credits as the main choice.

The engagement of trainees in all activities was very expressive of the interest and enthusiasm of its holdings. It was more dynamic and participative when was conducted the group activity. One possible reason for this adhesion is to be a short course and where the subject was the main motivation of participants.

Most trainees had never participated in a training online and were very pleased with the results of learning.

In our opinion a key aspect of this type of training course is the introduction of structured model, with specific timings regarding activities, in order to motivate learners and decrease a physic distance thus maximizing both individual and work group contributions.

Undoubtedly work group activities showed more dynamism, enthusiasm and collaboration. It must be noted that learning and teaching of any software exclusively through online distance learning and directed learners with different levels of knowledge is not easy. As a result this can lead to practically no interaction amongst them.

Nevertheless in LLL ongoing teacher training although students had different levels of knowledge about Excel and some of them never experienced online distance learning or knew the Moodle plataform, an excellent level of interaction and dynamism was achieved, namely if we compared this course with other lengthier courses.

Furthermore, as a trainer I noticed that the final assignment had the same level of quality of a final assignment produced in a face-to-face classroom course.

This shows once again that online distance learning namely in LLL ongoing teacher training allows sustainability in learning.

388 - Continuous Teacher Formation in Virtual Learning Environments: Risks of Depersonalized Pedagogical Relations

Marcus Vinicius Santos Kucharski

Nucleus of Research on Interactive Pedagogical Processes – NUPPEI, School of Human Sciences, Languages and Arts, Tuiuti University of Paraná – UTP (Brazil)
marcus.kucharski@utp.br / marcus_kucharski@yahoo.com.br

Abstract: Bringing the best possibilities of digital technologies to the benefit of education is a positive trend we observe nowadays. Many continuous formation courses for teachers are offered by numerous schools and educational groups all over the world. In Brazil, we had the opportunity to research the establishment of interpersonal pedagogical relations in one of the most innovative initiatives in this area, and the conclusions we came to were disappointing from the standpoint of those who firmly believe that, digitally-enhanced or not, educational processes are, above everything else, personal, and taking this characteristic away from them leaves little or no significant progresses in building new or remodeling meaningful knowledge.

Keywords: Continuous teacher formation. Virtual learning environments. Interpersonal pedagogical relations.

INTRODUCTION

Continuous formation is a major challenge in times of scientific and technological improvements that demand teachers to develop competences for working with the wide array of possibilities brought into their schools – as well as into their own lives, for that matter – by digital technologies. Students are ever more rarely resourcing to traditional libraries for research, preferring to use online search engines to access and select contents; multimedia, pictorial and textual materials related to any conceivable school subject are freely accessible in numerous websites, blogs and online broadcasting services, usually being a lot more attractive than our presence and voice alone could ever be – potentially valuable additions to our traditional classroom dialogical competence; new or revised scientific knowledge is immediately made available through the Internet, creating an amount of relevant (and not seldom controversial) information that can be nearly impossible to keep up with in its extent and implications. Nevertheless, the advent of such possibilities has been constantly – and misguidedly, as we see it – sensed by teachers rather as an invasion of their space and a threat to their established knowledge and professionalism, to the extent of being pointed out as being the inescapable formula of a disguised proletariat (Antunes & Braga, 2009).

Given that younger students have been pervading schools with their digital lifestyle and revigorated way of working and collaborating (Veen & Vrakking, 2006), a more defensive attitude from their teachers has been a common and reasonable way of responding to the aforementioned "invasion". Reasonable as far as it is expectable from anyone who perceives himself surrounded by innovations too many to take in at once; it is unreasonable, though, when it seals schools from what is trending in science, technology and, consequently, in life. The use of digital networks for communicating, researching, exchanging and expanding knowledge can no longer be a stranger to any actor of the pedagogical processes.

Research has proven that creating and supplying rich multimedia laboratories in schools is far from sufficient to guarantee that they will be properly used to educational profit. Teachers need to know how to bring technological advantages into their professional practice without underrating and, thus, underusing them to their own (and their connected students') disappointment. Negative experiences with technology frequently result in negative views of its adequacy for formal learning.

If we agree about the existence of a significant gap between students' and teachers' grasp of digital technologies with advantage for the firsts, then a solution for it is promoting digital literacy among the latter. Currently, a widespread way to do so, considering most teachers' hectic work schedules, has been encouraging them to take part in continuous formation courses with the prevalent use of such technologies. We are not referring to courses on how to incorporate digital technologies to their classes or methodologies, but to those which invite them to review, discuss and improve their existing competences in their own fields of knowledge with ubiquitous use of digital technologies to achieve it.

Between 2009 and 2010, a relevant public-private partnership between the government of an economically prosperous city from the state of São Paulo (Brazil) and one of Brazil's largest educational content and technology developers resulted in an experimental project that tended to 405 (four hundred and five) public elementary school teachers in free, internet-based and multimedia-enriched courses on current issues of Language and Mathematics teaching strategies, the successful completion of which would be a key element considered for career advance. As they participated in the courses, they would be exposed to and need to make use of numerous intuitive multimedia learning objects, thematic blogging, online search engines, libraries and dictionaries, discussion forums and collaborative activities. The project was closely accompanied by researchers from the Pontifical Catholic University of Paraná (Brazil), resulting, among other research documents, in a doctoral dissertation which explored the striking discrepancies between the proposal's outstanding pedagogical theoretical framework, its actual management and poor results, centering its analysis on major failures caused by the depersonalization of the process, a contradictory educational procedure to that of the project's original foundations (Kucharski & Torres, 2010).

PRESENTING THE COURSES' PROPOSAL

The terms of the aforementioned public-private partnership left the private educational multimedia group with the responsibility of creating an innovative, intuitive, easy to understand virtual learning environment (VLE) through which the proposed courses would be available and where all interpersonal contacts should happen (participant-participant / participant-tutor / tutor-participant / tutor-tutor). The pedagogical logic underlying the methodology of choice for each one of the courses' classes (or units, as they were called in the VLE) should mirror updated pedagogical research on each theme and on the use of digital technologies to enhance learning.

The VLE created to contain the courses featured all major modern possibilities of information and communication technologies (ICT): the capability of lodging and streaming audiovisual files, tools for synchronous and asynchronous written communication among all actors, immediate feeding of selected news relevant to the courses' areas, pages for presenting, illustrating and discussing pedagogical theories, links to interesting additional web pages, online educational databanks and libraries and more. But the most admirable features of all this package were the pedagogical principles that underscored the proposal as a whole.

General guidelines of the project proposed that each topic presented would stem from teachers' most frequent classroom difficulties while working with the contents listed in the National Curricular Parameters (Brasil, 1997 & 1997b), which are official documents from the Ministry of Education that list and discuss selected contents and the methodological approaches to work them in the disciplines of Portuguese and Mathematics in the first four years of Elementary School. Thirty-six multimedia study units were then developed to build the courses: 17 (seventeen) for specific Portuguese teaching topics and 19 (nineteen) for Mathematics.

Each study unit obeyed a sequence of activities meant to reflect the best practices and state of the art pedagogical thought on the specific subjects, on continuous, lifelong teacher formation and on distance education principles, especially those about collaborative, constructive working attitudes based on codependence and shared experiences and responsibilities for building new or deeply modified pedagogical knowledge.

Philippe Perrenoud's (2000) principles were central to define the didactical and pedagogical sequence of facts for the units. Each one would start with a multimedia presentation of a common classroom problem-situation related to the teaching of the topic discussed in that unit; the second step would include sections in which empirical and theoretical perspectives on the topic would be exposed and contrasted so that participants would be naturally encouraged to move to the third – and perhaps most meaningful – methodological step: online collaborative research and discussion that would promote renewed, negotiated views on the problem by establishing direct (though not necessarily synchronous) contact among participants and of those with experienced tutors. Next would be going back to classrooms and working or reworking the topic under new, more informed and intensely discussed perspectives. The fifth step involved returning to the VLE and sharing viewpoints on the recent experiences, either positive or not, providing reflexive feedback, confirming results or restarting the discussion cycle as needed. Such steps confirmed the logic of moving from practice to theory and back to practice, recommended by many celebrated authors and adequately presented by Marguerite Altet (in Perrenoud, Paquay, Altet & Charlier, 2001).

The aforementioned participants, then, voluntarily enrolled at no cost for the courses and were given two months to work on the thirty-six study units, fulfilling individual and collaborative activities, at the end of

which period they would undergo an electronic evaluation covering the topics of all units, as well as fill out a self-evaluation form discussing their impressions of the experience as a whole.

FOLLOWING THE EXPERIMENT: METHODOLOGICAL APPROACH

Following the courses in real-time, as they happened and participants interacted, came up as a rich possibility for research on interpersonal pedagogical relations in a virtual continuous formation environment, a possibility that was quickly overturned by the private educational multimedia developer, which suspected that the virtual presence of the researchers could be perceived as lurking, shying participants from more natural involvement. Given that their position would not change even before the possibility of having the researchers totally unidentified, the option offered was the elaboration of a research questionnaire that would be made available to participants and, later, total access to their answers to the survey plus all written materials produced by the participants during the course: comments, forum and blog interventions, questions and answers *to* and *from* tutors and students. Once these materials amounted to all interactive production on the VLE, the researchers acquiesced to the possibility.

The approach to the data whose access was granted to the researchers would have to be built from a combined methodological choice. The content itself would necessarily be first scrutinized using Content Analysis procedures (Bardin, 1995) having Atlas.ti as the analytical software of choice. This first reading would allow the surfacing of discursive categories whose deictic and contextual implications could be more deeply examined and understood under concepts of Pragmatic Linguistics (Lozano, Peña-Marín & Abril, 2002). Group interaction implications would be better evaluated from a methodological standpoint that considered the participants' community of practice as an effective discursively-bound societal formation (Mey, 2001) in which all written interactions would be valid expressions of cultural nature, following principles of Optimal Relevance (Sperber & Wilson, 1996) and being suitable material for an exercise of Virtual Ethnography (Hine, 2008). This combined, qualitative approach that would allow important changes of analytical focus as information grew in quantity and quality fitted the principles of Development Research (Van Den Akker, 1999).

A disappointing discovery

As the data were closely analyzed, troublesome facts soared. In quantitative terms alone, active participation in the units' proposed activities was far less than sufficient. Each one of the thirty-six study units proposed at least one discussion forum and one blog entry per participant for the minimum necessary work to finish them to be considered done. If we keep in mind that 405 (four hundred and five) participants signed up for the courses, we should have, after they were finished, at least 29,160 (twenty-nine thousand, one hundred and sixty) collaborative, discursive entries in forums and blogs, but all we could find were a mere 979 (nine hundred and seventy nine) entries from students (3.35% of the expected minimum participation). Qualitative inspection of all entries showed that only 112 (one hundred and twelve) of all 405 originally enrolled participants became actively involved with the courses' collaborative activities, while none was able to complete all of them. When asked for the number of people certified for their participation in the courses, neither the client city nor the certifying educational group answered. This clearly called for deeper investigation and understanding of the fact.

It was decided, then, that, together with the proposed discursive analysis of all written materials resulting from the established pedagogical interactions, a deeper, qualitative approach to the answers on the research questionnaire would be carried out for everything provided by all 112 effective participants; answers were sent back from 20 (twenty) participants (16% of the sample). Their positions were rather disturbing. In terms of the perception they had of each instance of the study units,

➢ theoretical instances of the courses, where all study efforts were essentially individual in nature, were preferred by 73% of the respondents;

➢ the first of the courses' instances that valued contextualization of the discussion topics did not do better than fifth of nine possible positions;

➢ the specific instance that called for active collaboration among participants came up in the penultimate position, *after* the Bibliographic References and just one vote above the units' self-evaluation exercises.

As they were asked about their qualitative perception of collaborative discussions and knowledge-sharing moments of the courses,

- ➤ 41% of the respondents said they simply did not exist. 33% of them said there were few;

- ➤ only one of the respondents said that, when in doubt or wishing to widen the discussion of a course topic, she would look for the teacher responsible for tutoring the virtual group. All others affirmed they would look for colleagues who worked in the same schools.

The last answer seemed contradictory with the seemingly large number of 979 entries in the collaborative activities; they were, though, proportionally few when compared to the minimum expected from 405 enrolled participants (3.35%), and represented no more than 13% (thirteen per cent) of the minimum expected from the 112 effective participants. Nonetheless, these "few" interactions were definitely meaningful. The pragmatic content analysis of the deictic aspects of the written interactions in the VLE showed that:

- ➤ in only 52 (fifty-two) of them, tentative collaboration could be perceived, being 32 (thirty-two) personal, *student to student* comments (mostly giving practical advice on pedagogical procedures) and 20 (twenty) of *student to ideal reader* type – being the ideal reader an impersonal entity with which one establishes a unidirectional "conversation", usually in the form of personal opinions not directed to anyone specifically but to everyone, potentially, where neither the participant nor the ideal reader are personified by first or second person pronouns, in a referential type of text. This ideal reader was the focus of a total of 741 (seven hundred and forty-one) entries.

- ➤ In 194 (one hundred and ninety-four) entries, the participants made discursive moves toward a *character-narratee* (Jouve, 2002), representing themselves in first person and the narratees in second person (singular or plural), usually encouraging the latter to provide any continuation to what was being exposed, but not necessarily counting on it.

- ➤ In 690 (six hundred and ninety) entries, there was a clear prevalence of the discussion topic, as theoretically presented, over the participants' perceptions or opinions about it, reducing the textual entry to a mere repetition of what had been presented in the courses' units. In only 60 (sixty) entries did the participants' perceptions or opinions were strong enough to propose a new perspective over the discussion topics, starting collaborative discussions that, unfortunately, were rarely ever continued.

Courses meant to generate digital inclusion and awareness of technological possibilities for teachers failed immensely to follow a basic principle of contemporary educational theory: being a collective, collaborative exercise where anyone's perspective is just as important as anyone else's for discussing and reconstructing a common-interest topic. In failing to do so, these courses faced great evasion and became a symbol of loss of intelligence, time and resources. It became tempting to search and discuss probable causes for their failure, and it was clear that concentrating our focus on the non-established interpersonal pedagogical relations was a promising path.

Failing to establish relations where they were needed
The noticeable dysfunction between the courses' pedagogical proposal and what could be perceived from analyzing their interactional data drove our attention to the search of the mechanisms used to ensure the best conditions for collaborative interactions to take place. Such mechanisms should be visible embodiments of the theoretical proposal, beyond the simple presence of collaborative tools as forums and blogs, encompassing especially methodological directions toward collaboration. This was where we found the most significant failures of the process.
Perhaps the most outstanding of these failures was the textual construction of the courses' units. Purely referential, impersonal texts prevailed in all units, never leaving openings for any linguistic strategy to put writer and reader in closer contact. This played against every possibility of establishing a more conversational tone, amplifying what Michael Moore calls transactional distance (Moore, 2008), adding psychological distance to the territorial one, far from all best practices for collaborative distance education activities – at least from the standpoint of whomever opposes the lonesome, prescriptive, self-instructional approaches to it.
Such impersonality certainly came as a shock for people who were, in most cases, for the first time in touch with the educational possibilities of the digital world, and whose professional lives had historically been centered on human interaction – independently of how traditional, teacher-centered their methodological

approach might have been. Following those course units did not seem to differ from reading a book in which the rare invitations to think and discuss are not but rhetorical. The voice of authority, that should represent the active participation of a more experienced peer (the author, in this case), always came with the weight of being totally extra-diagetical (JOUVE, 2002), unseemingly from a "real person" which could be perceived as an amiable instance, but rather as the infallible, not-debatable voice of a higher establishment.

Whenever individual people or small groups feel put up against a higher, stronger establishment, they tend to feel diminished in their possibilities of feeling uncertain about its principles, let alone trying to bring them into wider discussion. In the specific case of the analyzed courses, the prevalence of this kind of voice of authority contributed to shrink the possibilities of the perception of knowledge as a result of conscious efforts based on collective values, culturally and historically-bound and, thus, prone to change, evolve.

One could reason that such impression of solidity and undisputability is quite important to maintain an aura of trustworthiness to cultural or scientific knowledge; but that would mean to miss the point on the fact that knowledge is trustworthy for just as long as it serves its community well. If methodological approaches to certain school contents seem to be problematic enough as to generate continuous formation efforts, it is an important sign that not all is well, thus, should not have options presented as undisputable facts. This reinforces our certainty of having come across a remarkable inconsistency by analyzing the "inversed coherence" present in these courses.

This depersonalization of the voice of authority in the courses was also true to the opening texts of the forums and blogs, (in)directly forcing participants to assume the same tone, in a defensive disposition, preferring the safety of not exposing themselves to open criticism because of a different point of view. In such cases, establishing no interpersonal relations at all was preferable to undesired exposition, which, if on one hand made "survival" in the courses a nearly risk-free experiment, on the other hand was fundamental to the maintenance of a status quo where nothing could be deeply changed in the participants' pedagogical competences, either for better or worse.

The way teachers in charge of tutoring the courses were presented in the collaborative activities was not better. They would only be identified as Language Teacher or Math Teacher, differently from all other participants, whose names were always visible to everyone. This was part of a sorrowful institutional policy from the part of the content provider who, in spite of all recent research and publications saying differently, demanded that the tutors be as low-key as possible, leaving almost all the research, activities and thinking to participants alone; this included keeping tutors anonymous, and asking them to provide as little interference as possible. This resulted in great distortion of the function, which can be assessed by the following:

  ➢ the nearly non-existent moments in which tutors were directly sought by participants in order to solve a doubt or expand a discussion about any given topic;

  ➢ an explicit preference for self-study strategies verbalized by 80% (eighty per cent) of the interviewed participants in spite of the courses' theoretical endorsement of dialogical relations and collaborative attitudes toward knowledge building;

  ➢ the transactional distance reinforced by the tutors' wrongly encouraged absenteeism from discussions. In Language collaborative activities, there was one entry from tutors to every nine from participants; in Math, one from tutors to every four and a half from participants. Interestingly, the Math tutors adopted not only a policy of being more present, but also more dialogical in their entries, which did not necessarily brought participants to more effective partaking in the discussions. This seems to point to a crack in the general tutoring policy of the courses, once this specific group of tutors seemed to stray from it in the direction of a position that seemed more adequate to them;

  ➢ a total of 45 (forty-five) passages in which participants made serious conceptual mistakes for which they were not approached or corrected by the tutors, fragilizing the teaching/learning process.

The immediate consequences of the depersonalization of pedagogical relations in the observed courses went far beyond the high evasion numbers; it also prevented the establishment of rich dialogical relations, not allowing the free flow of information and the arising of renewed knowledge. What could be concluded from the observation of all available data was an eye-opener to all involved with the new methodological and epistemological possibilities of digital solutions applied to education.

CONCLUSION

The rich interpersonal pedagogical relations, as praised in the VLE's and its courses' theoretical frameworks, simply did not take place. The depersonalization of the relations established within the courses made it

almost impossible for the participants to realize that they should interact freely and constantly among themselves and with the tutors in order to solve real problems that they face daily in their classrooms with the help of a rich presentation of new theories about such difficulties. By means of an impersonal voice of authority that prevailed in all courses, and of an unfortunately passive attitude from tutors, participants felt more comfortable in approaching the opportunity the same way they would reverentially read a book, being passive recipients of information instead of active builders of their own competences.

The opportunities of establishing long-lasting productive relationships among teachers with similar interests (new societal formations) were (in)directly devalued, impoverishing the relativization of time and space, the most valuable pedagogical possibility of virtual environments.

Adopting a neutral textual persona in textual interferences throughout the courses' collaborative spaces was another negative consequence of depersonalized relations. According to meaningful (Ausubel, 1978) and andragogical learning theories (Knowles, Holton & Swanson, 2005), there is nothing impersonal about learning and teaching, once they result from individual and group interests, selections, negotiations and basic agreements, just like science, and every knowledge is then accommodated into everyone's knowledge structures the way it will fit them best – personalized, then. If the whole process of negotiating meanings to build new understandings happens in a rather neutral fashion, we reach an unsurpassable incoherence and become tied up to the non-enriching possibilities of repeating the already-known.

From what we have been able to see in the last few years of dedication to researching digitally-enhanced teaching and learning, the tendency of depersonalization in VLE-based courses is more of a trend than not, specifically so when educational initiatives face the challenge of providing formation to large, geographically-sparse groups. This usually results from a combination of factors, some of which come into view almost immediately:

> *Time constraints* make it more attractive to give participants a more passive role, so they can be fed a whole lot of information in less time; this variable makes us think if quantity is not being perceived as quality, which would be a major mistake. Fewer contents with more time for collective reflection and reconstruction usually bring better, more relevant results.

> *Financial calculations* tend to signal against having larger, more active groups of tutors following the discussing/learning processes of participants. Here, there is a significant ideological component to the reflection; while entrepreneurship in education is not disqualifying in terms of the potential quality of its courses, the financial balance must be rethought from a different perspective: quality courses with greater participation are usually better spoken of in the long run, combining educational quality with positive, long-lasting results over time.

> *Lack of specific formation* for teachers acting as tutors is another contributor to less relevant action from their part in virtual courses. Working in traditional classrooms bear little (if any) resemblance to the kind of work necessary in virtual environments. Students in virtual courses must be constantly, positively provoked to participate, their answers must be commented, put up for further discussion, be considered and pointed as relevant at all times and a specific learning unit or activity can not be finished before some wrapping up and trimming is performed, not to leave any reasonable doubts unnoticed and not discussed. Tutorial silence is the near equivalent, in virtual classrooms, of a traditional classroom without a teacher.

> *Uncertainty of tutors* about the subjects they are responsible for in virtual courses is a key factor for less relevant contribution to the teaching/learning process. This is not true for virtual courses only, but just as vital for the traditional classroom. Virtual courses, in their own turn, usually unite groups of different understandings and competences in terms of their subject, and this is guaranteed to bring up all levels of questioning from participants, from the most basic to the most elaborate, intricate questions and opinions. Tutors should not be freely hired based only on their formal education on the area of the offered courses, but should represent a higher variety of thought, research and development in that area. Of course there are no people capable of offering definitive answers to all questions about a specific subject, but an extensive repertoire of reading, discussing and publishing about the most recent trends of science is a fundamental ingredient to directing discussions to higher, more adequate levels. What we usually see when researching virtual courses are tutors whose command of their areas is only a notch above other participants', causing forced silence or less significant input to the discussions.

All these factors, combined with less-visible ones, were defining for the negative results in terms of establishing a real group of collaborative work in the courses we researched, causing high evasion and less significant (re)construction of knowledge, taking an opposite road to that planned in the theoretical framework of both the VLE and the courses offered therein. Here is an interesting contradiction we perceived: there were no theoretical discrepancies between the theoretical proposals of both, but a procedural one when the courses were effectively happening.

Many participants were rapidly driven to withdrawal from the activities and, for those who insisted on going on with the courses, a more unattended to, lonesome position was reserved, bringing no more gain than a trip to a local library could offer. All these sad results stemmed from a mix of factors that determined a near totally depersonalized approach of the courses' topics and, especially, of the participants. This is not what we expect from initiatives that propose to make significant use of new technologies for the benefit of learning.

Here is one thing we could learn from today's generations Y and Z representatives' approach of their common online activities (Veen & Vrakking, 2006): overcoming obstacles is learning, so interesting challenges move them toward a common goal. This movement involves a lot of discussing, negotiating and strategical thinking that takes place in virtual environments, synchronously or not, but goal-oriented and focused. In such environments, more experienced peers take turns in helping less experienced ones, not unusually by allowing them some minor mistakes until they are ready to discuss what they feel is being performed inadequately – and it always happens in very personal scenarios: though nicknames and avatars usually take up the place of the actual people behind them, these personas usually act in very predictable and coherent ways, as real names and real people could and should in online courses. None of it was present in the courses we researched – neither in numerous other ones we have come across in our line of work , but seem to be the yet indiscussed way to better using technology and its possibilities for really significant, *personal*, learning.

401 - Teacher Learning in Transition: Participatory Practices in Digital Age Environments

Catherine McLoughlin

Australian Catholic University, Canberra, Australia
catherine.mcloughlin@acu.edu.au

Abstract: The development and uptake of digital tools and social software is bringing about massive societal and economic change. Web 2.0 technologies have been widely recognized and promoted for their affordance of easy publishing, sharing, socializing, and communication. Web 2.0 practices are activities that use Web 2.0 technologies, embrace a learning paradigm that values participatory culture, emphasize collaborative learning and peer-to-peer interaction, involve active participation and engage learners in knowledge creation activities. Web 2.0 practices help individuals develop essential skills needed for success in today's world, such as critical thinking, problem solving, communication, and collaboration.

Although higher education has been taking advantages of Web 2.0 applications to create technologically-enriched learning experiences for students, most of the existing Web 2.0 literature shows that educators do not use those applications to their full potential. That is, the participatory, interactive, collaborative, and social aspects are often missing from learning activities. Furthermore, the impact of social media on teacher education has been rather limited. While expectations have run high about web-based instruction, virtual worlds, social media and the raft of "Web 2.0" tools, the impact on professional learning is not well documented. Recent research globally indicates that change is constant and that challenges educators need to be fully aware of include the adoption of Web 2.0 applications to support teaching and assessment in meaningful and authentic ways. The recent emergence of approaches to learning that are based on self-determination and networking such as heutagogy and connectivism help us understand learning as making connections with ideas, facts, people and communities. Learning for the professions has grown beyond mere consumption of knowledge and become a knowledge creation process. The new effective teacher must think more about process than content, enabling learners to operate in the digital world rather than learn a discrete body of facts. The paper will present the teaching and learning possibilities accompanying the social, participatory and collaborative tools that have emerged in the Web 2.0 era. For beginning teachers, competence in e-learning and the capacity to employ these tools to support lifelong professional learning. As technologies continue to change, there is a now a stronger emphasis on teacher learning and that is proactive, experiential and mediated by digital tools. The processes that are involved in teacher professional development are discussed, and linked to the enabling affordances of digital technologies. The complexity of teachers learning and teachers' knowledge is acknowledged and theorised, and evidence is presented that digital tools and their affordances can enable and support teacher learning in a number of productive ways.

INTRODUCTION: TEACHER KNOWLEDGE AND LEARNING

With the growth and expansion of the Internet and social computing, digital tools are widely used to mediate social interactions and communication. Social networking sites such as MySpace and Facebook are part of a larger suite of social computing tools that collectively fall under the label of Web 2.0. Extensive research indicates that these technologies are widely embraced and that the majority of students now carry a mobile phone, PDA and laptop. These technologies break down barriers at a number of levels, such as private and public space, learning space and social space. Along with the ubiquitous uptake of social networking tools, there has been an increased focus on the importance of students learning social media skills and digital literacies (Siemens, 2007).

In this ever changing context, mediated by digital tools, the expectation so that teachers become experts in the use and application of ICT tools. As described by ISTE (2009) teachers are now expected to ensure that they can support digital age learning by developing fluency in the use and application of digital tools and social media in the classroom. The aim of this paper is to identify the aspects and processes of the professional learning of teachers, and what part digital tools may have in the learning of teachers. The paper argues that there is enormous value in exploring the potential of web 2.0 tools for profession learning. While several models of teacher professional development have been applied to identify teachers' needs, digital age

thinking and networking have changed expectations of what it is to teach and learn in 21st century classrooms. There is currently little research that investigates how teachers learn with social media and digital tools. To address this gap, the paper considers pedagogical change and presents a number of theories of learning linked to digital age technologies and greater global connectivity. Next, the paper investigates what is known about teachers learning, and compares a number of theoretical models that provide insight into the nature of teacher knowledge and learning. Following this review, the core components of these models will be distilled and linked with the proposal that digital tools and their affordances can enable and support teacher learning in a number of productive ways.

Pedagogical change and professional development in the information age

Behind Web 2.0 is a vision that involves using the internet in more creative, social and participatory ways than was previously the case. Web 2.0 can exploit the internet's educational potential for social learning and teaching, as well as informal learning, and brings in an increased emphasis on autonomy, interactivity, creativity and collaboration (Alexander, 2006). One of the ways in which Web 2.0 is making an impact is through the creation of internet-based communities of teachers, through services such as blogs and wikis. While this might be considered an indirect mode of influence on learning, it is probably a significant one. Dissemination websites aimed at practitioners can create a community of discourse for teachers who have a shared interest in the practices and the adoption of innovative pedagogies. To assist teachers in their own professional learning, many websites are beginning to support the exchange of shareable learning objects (see for example TeacherTube). This is consistent with a trend for teachers to seek professional development activities online, achieve efficiency and effectiveness, through access to shared ideas and lessons plans. The theme of this paper is to conceptualise how teacher professional learning might be supported and enhanced through the affordances of web 2.0 technologies. By applying social-cultural and connectivist learning theories, and by examining innovative views of learning that are gaining currency it is possible to reconceptualise teacher professional learning, as social, experiential, reflective, participatory and constructive, and capable of being supported through distributed networks and mediating artefacts.

Emerging terms, theories and pedagogies

There are distinct calls for a rethinking of pedagogy to meet the demands of an era in which ubiquitous computing and social connectivity mediated by ICT are reshaping academia. This is evidenced in the emergence of a myriad of buzzwords and terms accompanying ongoing debates on issues depicting changing priorities in pedagogy. For instance, Ashton and Newman (2006, p. 828) note that we have *pedagogy* (teaching of children) *andragogy* (teaching adults), *ergonogy* (teaching people to work). However, none of these terms captures the imperative of innovative knowledge sharing and creation required in the 21st century. Nevertheless, a number of concepts now in use signal the change from traditional pedagogies to forms of teaching and learning engagement where learners having greater levels of agency, social connectedness and autonomy. For example, some theorists consider *heutagogy,* in which learning is completely determined and directed by the learner, to be the next stage in the evolution of andragogy (Hase & Kenyon, 2000; Aston & Newman, 2006). Heutagogical approaches place the ultimate responsibility for learning on the learner and are aligned with the expectation that individuals must attain learning-to-learn and self-direction in order to succeed in the knowledge society. They are based on the premise that an individual learns continuously through interaction with his/her environment and throughout his/her lifespan, often in the face of ambiguity and need. These conceptualisations challenge us to maximise the potential for teacher learning by employing the right blend of metaphors, frameworks and paradigms that capitalise on contemporary social networking tools and ICTs that people use in their everyday lives. Table 1 summarises a number of theories and paradigms of learning that have emerged in recent education and teacher development literature.

Table 1: New and emerging learning theories

Author/date	Theory	Principles	Scope for teacher learning
Lave and Wenger (1991); Wenger (1998)	Communities of practice	Members of a community of practice are practitioners who develop a shared repertoire of resources: experiences, stories, tools, ways of addressing recurring problems—in short a shared knowledge base	Engagement in "legitimate peripheral participation" so that through participation, building of social and intellectual capital of the community is enabled
Hase and Kenyon (2000)	Heutagogy	Goes beyond andragogy by advocating self-directed learning, capability and pro-active participation	Focus on knowledge sharing and creation of new knowledge from existing experience
Tangney, FitzGibbon, Savage, Mehan and Holmes (2001)	Communal constructivism	Teachers actively create their own knowledge, but are also active in the creation of knowledge for a wider learning community	Create tasks to engage learners in knowledge creation
Laurillard (2002)	Conversation theory	Teacher learning occurs through conversations about a subject matter which serves to make knowledge explicit and to promote reflection	Teacher learning is enabled by conversation, reflective and reciprocal dialogue.
Siemens (2005)	Connectivism	A theory that combines and integrates principles explored by chaos, complexity theory and networking. Making and sustaining connections is more important than simply knowing	The learning process is characterised by connecting information sets and by making the connections between events and ideas on a global scale
Brown (2005, 2006)	Navigationism	Teachers should be able to find, identify, manipulate and evaluate information and knowledge and be able to share in the knowledge production process.	Navigationism is a broader and more inclusive term than constructivism but includes knowledge creation. Teachers develop skills in navigating digital landscapes

Each of these theories hold some promise and scope for consideration when thinking about the development needs of teachers. The pedagogies depicted in Table 1 signal the change from traditional pedagogies to forms of teaching and learning engagement where learners having greater levels of agency, social connectedness and autonomy. For example, some theorists consider *heutagogy,* in which learning is completely determined and directed by the learner, to be the next stage in the evolution of andragogy (Hase & Kenyon, 2000; Aston & Newman, 2006). Heutagogical approaches place the ultimate responsibility for learning on the learner and are aligned with the expectation that individuals must attain learning-to-learn and self-direction in order to succeed in the knowledge society. Similarly, conversation theory and constructivism indicate that learners learn continuously through interaction with their environment and throughout the lifespan. A theory that has emerged to describe the social, interconnected and community-based characteristics of learning in contemporary times is connectivism. Connectivism strives to overcome the limitations of behaviourism, cognitivism and constructivism, by synthesising the salient features and elements of several educational, social and technological theories and concepts to create a new and dynamic theoretical construct for learning in the digital age. These conceptualisations of pedagogy and learning challenge us to maximise the potential for learning by employing the right blend of metaphors, frameworks and paradigms that capitalise on contemporary social networking tools and ICTs that teachers can use in their everyday lives for understanding creation and reflection.

MODELS OF TEACHER KNOWLEDGE AND LEARNING PROCESSES

Teacher knowledge is best seen as dynamic, and hence inseparable from the processes of learning. Teacher learning in turn is an active, experiential process, through which knowledge is enacted, constructed and revised. This does not however mean that teacher knowledge is only to be developed through experience and reflection. Hargreaves et al (2003, pages 197) commented that teachers are agents of change and that

"teachers are having to learnt o teach in ways that they have not been taught". Furthermore, lifelong learning for teachers as been recognised as essential according to Nonaka (1991).

> Personal knowledge is comprised of a network, which feeds into organisations and institutions, which in turn feed back into the network and then continue to provide learning to individual. This cycle of knowledge development (personal to network to organisation allows learners to remain current in their field through the connections they have formed.

Shulman's (1887) model of pedagogical reasoning was originally developed as a foundation for teaching reform. The model comprises actions that a teacher undergoes during the teaching process including comprehension of subject concepts, transformation of subject knowledge into teaching and instruction, evaluation of learning, reflection and new understanding of the learning process, self and the teaching process. The most original and significant part of Shulman's classification of teacher knowledge is the category of pedagogical content knowledge (PCK), indicating that teachers do possess a specialised knowledge base. As teaching continues to evolve, several researchers have revisited Shulman's model with a view to exploring how its relevance in the age of Web 2.0. Starkey (2010) has modified Shulman's (1987) model in order to reflect the evolution of learning theory since that time. The original model is grounded in constructivism, while the revised model includes connectivist approaches that assume that teachers create knowledge through connections in an open, digitally connected world where they operate in many overlapping communities. Teacher knowledge is complex and multi-faceted, and the nature of teachers' professional learning needs to be made more explicit. More recently, research attention has been given to expanding traditional notions of behaviourism and cognitivism, and to considering the nature of social interaction between people. Thus, the theories depicted in Table 1 draw together the ideas of distributed cognition (Brown, Collins & Duguid,1989), situated learning, and communities of practice, and are linked to a view of knowledge that suggests that cognitive functioning, rather than residing in individual minds is dispersed among people, objects, tools and technologies. In addition, this socio-cultural perspective leads us away from thinking about knowledge as a state of mind, to "knowing" as a social process.

How do teachers learn?
The phrase "professional knowledge" is used widely among teacher educators with the assumption that the definition and the processes of acquiring this knowledge are obvious. At the same time, published standards specify the performative criteria against which teachers are expected to demonstrate their teaching skills. The language used about teacher learning i.e. "training" and "development" suggest that the process itself is instrumental and unproblematic. Researchers have on the other hand, shown that the learning process is considerably more complex and that the global, digital age context is bring about massive changes in how teachers learn (Goodson, 2003). As concluded in the previous section on emerging pedagogies and theories, teacher knowledge is dynamic rather than fixed and constructed rather than transmitted.

Teacher learning is multifaceted, and includes component processes of experience, reflection and social construction, as teachers' work is cyclical and dynamic. Schön (1987) critiqued the ideas that education consisted in the transmission of data. Being able to reproduce codified knowledge was no guarantee of being able to apply it because so many problems existed in "indeterminate zones of practice - uncertainty, uniqueness and value conflict" (Schön, 1987, 8). He also emphasised that reflection on action was a significant means of learning from experience, and that the knowledge gained from reflective practice can be drawn up in future situations. Another aspect of how teachers learning through Vygotsky's (1978) "zone of proximal development" when for instance there is a process of mentoring and coaching of new skills. The context and environment for teacher learning is also important and is encapsulated in the idea of "situated learning" whereby the development of skills, knowledge and competencies may be supported by individuals, peers, objects and tools. Somekh maintains that professional knowledge building flourishes in environments that enable purposeful activity and distributed cognition (Somekh, 2001). In order to understand the role that digital technologies play in learning, we need to adopt a model that takes into account the elements of learning derived from a number of learning theorists. These elements would include purposeful activity, the social and interactive dimensions of cognition and the enabling role of digital technologies.

Models portraying the complexity of teacher learning
A number of models have been developed in an attempt to portray the complexity of teacher knowledge and learning, and all have overlapping features. These models are compared and summarised in Table 2.

All three models recognise that teacher learning is multifaceted and complex, and that development of teacher skills and knowledge is highly interactive, individualised social and interactive. All acknowledge that teacher learning and teacher knowledge are two sides of the same coin. Teacher learning involves active, experiential activities and through the processes of engagement and learning, knowledge is created, enacted, considered and revised. Pedagogical thinking is subject to many different influences and factors, and is a constant interplay between formal and informal learning, personal constructs and professional expectations, objective and subjective experiences. Therefore, the development of professional skills and competencies is very much an individual learning trajectory, and that it may be enabled by interplay of factors, including practical experience and participation in communities of practice. In the following section, the five competencies described by Shulman & Shulman (2004) as reflection, vision, community, capability, motivation, will be considered in the context of how digital tools can be used to mediate and to support teacher learning.

Table 2: Comparison of models of teacher learning

Theorist and model	View of the teacher	Type of knowledge
Banks, Leach & Moon (1999) [Four categories of teacher knowledge]	Teacher seen as knowledge professional Complex and individual	Subject knowledge School knowledge Pedagogic knowledge Personal constructs
Hoban (2002) [Professional learning System]	Teacher knowledge as constant construction	Transformative and generative
Shulman & Shulman (2004) [Ready, willing and able]	Having vision, reflection, motivation, community, practice, understanding	Ready (having vision) Willing (motivated) Able (knowing and begin able to do)

AFFORDANCES OF DIGITAL TOOLS AND SOCIAL MEDIA

Web 2.0 applications like blogs, wikis, online social networking sites, photo- and videosharing sites and virtual worlds have known an exponentially increasing development and popularity over the past few years. Web 2.0 is what we call the democratized Internet or the Internet for everybody, since anyone in the world can easily go online and create and share files. This empowerment of the masses and engagement in mass participation is the fact that all the Web 2.0 technologies make it almost effortless for individuals to contribute to the web based discussion and provides accessible support for social interaction and exchange of one form or another. Web 2.0 tools (blogs, wikis, podcasts, social bookmarking, mash-ups) have transformed the Internet into a place for networking, community building and sharing collective experience, some have been led to describe this new phenomenon of massively distributed collective intelligence as "the wisdom of crowds". Social media and Web 2.0 can be seen as tools which afford learners the potential to engage in meaningful activities for learning. Such activity may be autonomous or collective, and can encourage communication beyond text-based media with easy publication of user-generated artefacts. Stimulating enquiry, supporting collaboration, engaging with new literacies and generating multimodal artefacts are all novels ways of developing knowledge and comprehension. The use of Web2.0 tools can enhance users' abilities mad can enable activities and provide structure. Several views of the affordances of these tools prevail. For example McLoughlin & Lee (2007, p.3) note how blogging entails typing and editing, which are not affordances in themselves, but rather enablers of affordances which include idea sharing and interaction. They identify the following categories of 'affordances' associated with Web 2.0 or social software:

a. Connectivity and social rapport
b. Collaborative information discovery and sharing
c. Content creation
d. Knowledge and information aggregation and content modification.

They also make the crucial point that social software affordances do not, by themselves, guarantee that effective learning will occur. This requires 'careful planning and a thorough understanding of the dynamics of these affordances' (2007, p.4). Conole & Dyke suggest taxonomy of features as follows: speed of change, diversity, communication and collaboration, reflection, multimodality, immediacy, risk, uncertainty. Much of

the research investigates how teachers can be better prepared to use these activities in their teaching rather than exploiting these tools as part of their own learning. It is therefore useful to weave together particular types of Web 2.0 affordances with the opportunities for learning that they might offer, and to provide exemplars of tasks. A useful way viewing this is to present a number of purposeful activities with the affordances of Web 2.0 (Fisher, 2006). These activities are not discrete, but are rather overlapping and interwoven (See Table 3).

Table 3: Linking meaningful/purposeful activity with affordances of digital tools

Distributed Cognition	Accessing resources
	Discovering and inquiring
	Composing, creating and presenting multimodal texts with digital tools
Engagement	Playing and exploring uncertainty
	Taking risks
	Responding to immediacy
	Learning though multidimensional interactivity
Knowledge creation	Creating and adapting ideas in dynamic ways
	Modelling
	Representing ideas in multimodal forms
Community and communication	Sharing ideas and resources
	Engaging in reflective dialogue
	Participating in local and global communities

Burden (2010) gives some examples of how Web 2.0 tools such wikis and virtual worlds can be used to support teacher professional learning. Collaborative wiki learning environments can be used by teachers to write and share their perspectives on a particular pedagogical problem. The wiki space provides an alternative context for learning and reflection where the teacher is freed from the constraints of the staff rooms and classroom and is afforded the space to articulate and share ideas. In addition, participation in wiki is a self-generated form of professional learning and can bring the teacher into global networks for sharing ideas.

Teacher learning through experience and construction in virtual worlds and 3D VLEs is enabled by the provision of alternative learning spaces which provide participants with "the ability to explore, construct and manipulate virtual objects, structures and metaphorical representations of ideas" (Dalgarno &Lee, 2010, p. 11). These authors identify five specific affordances that 3D VLEs might generate for learners:

- spatial knowledge representation;
- experiential learning;
- engagement;
- contextual knowledge; and
- Collaborative learning.

Each of these affordances might generate a learning task that correlates with the aspects of professional learning identified by Shulman & Shulman (2004: Table 3). The potential of virtual worlds such as Second Life to host alternative learning experiences for teachers is gaining momentum as the learning process is highly experiential.

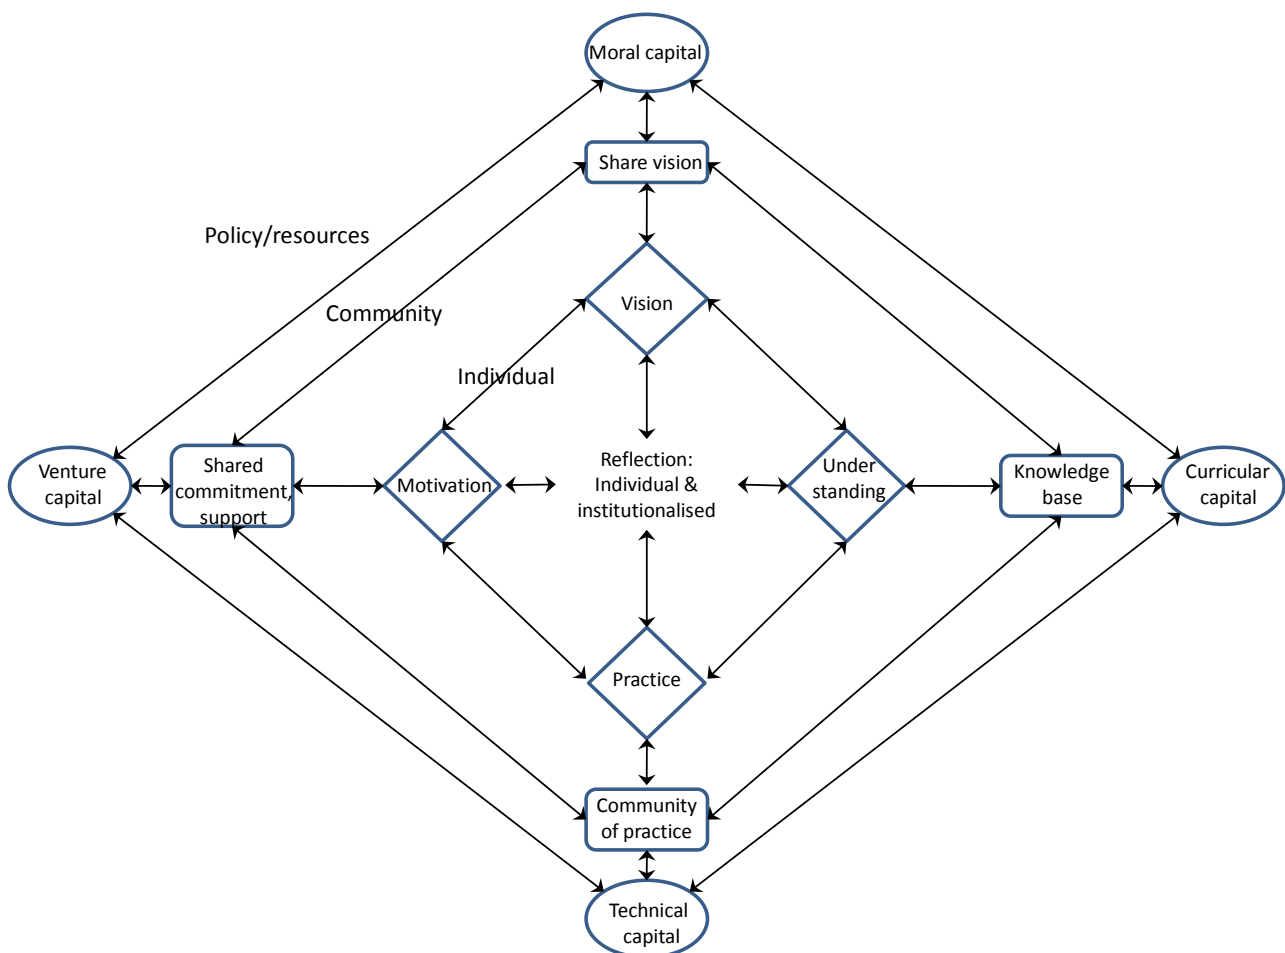
The next step is to demonstrate how these digital tools can be integrated into models of professional learning for teachers. While three different models of teacher professional learning was those of Hoban (2002), Banks Leach &Moon (1999) and Shulman & Shulman (2004). The latter describe teacher competencies as "ready, willing and able" and its aim is to assist in identifying and explaining teacher learning in a more explicit manner. As this model encapsulates the core ideas of both Hoban & Banks & Lee, it will be used to explore how digital tools can be used to enable and develop the attributes of vision, motivation, understanding, practice and reflection and community. This approach can also illustrate how experiences can be designed to support teacher reflection and professional learning in the information age. Given the affordances of digital technologies how might we best apply web 2.0 tools and social media in developing professional knowledge? Similarly Burden (2010) asks the question "Which aspects and affordances of Web 2.0 technologies are capable and suitable for mediating the elements of professional learning as depicted in Figure 1?


Figure 1: Model of teacher knowledge and learning (motivation, vision, practice, community, understanding and practice [adapted from Shulman & Shulman (2004) p 268

USING DIGITAL TOOLS TO SUPPORT TEACHER PROFESSIONAL KNOWLEDGE

According to Shulman & Shulman (2004) the accomplished teacher must have vision, a clear sense of classrooms as learning communities and motivation. In teacher education, vision means having a view on the purpose of education within society; views of learning and teaching; and positive proactive views on their own professional learning. The affordances of digital tools and social media have had a major impact on the social, economic and cultural aspects of society and education. Web 2.0 can support the five features of an accomplished teacher outlined by Shulman & Shulman (2004). Each feature is listed below and an example is provided of how social media can enable these characteristics:

Vision: Digital tools give teachers access to a global bank of ideas, views of learning and teaching and alternative strategies for teaching, learning and how schools operate in supporting learning and personal growth. Teacher vision is developed though informal learning and exploration of the multitude of websites offering professional development and teaching learning resources. Social networking sites allow individuals to connect, develop rapport, share interests, create community, and collaborate with peers. Many of these sites (for example, *Facebook* started off among small communities of college students in the USA, but have now spilled over into the professional worlds of work (e.g. *LinkedIn*).

Motivation: In the Shulman model motivation is defined as being willing to expend the energy and persistence to adopt teaching strategies that are aligned with their vision. Teacher capacity to engage with innovation and change is fundamental to the development of professional identity. There are many ways that digital tools can stimulate motivation to learning and grow as a teacher. For example, the web provides access to information and resources and allows participation in global e-communities of practitioners who share ideas and experiences. Through the affordances of distributed cognition, teachers can be motivated to expand their own frameworks for assessment and pedagogy.

Professional knowledge, understanding and practice: The openness of the web provides multiple representations of traditional disciplinary knowledge and can also mediate and amplify understanding when teachers engage with tools such as webquests, wikis, PDA's and mobile devices. These tools playa part on teacher representation of pedagogic content knowledge, and its implications for practice. McCormick & Scrimshaw for example, argue that teaching practice may change with digital tools in a number of ways i.e. by improving the efficiency of teaching, by extending the reach of teaching and learning and by transforming views of the subject itself.
.

Reflection: Critical reflection is regarded as a core component of teacher professional learning and Schon (1983) emphasises the need for teachers to learn from their own practices and from the experiences of colleagues and mentors. Reflective practice can be supportive by a range of digital tools and social media. Digital video and podcasts for example, can enable teachers to capture, observe and review episodes of teaching and to use them as levers for reflection, critical commentary and analysis.

Learning in a community: Digital tools can play a role in gaining access to communities at local and global levels, where they can express shared visions, and review emerging practices. By providing social online spaces for professional communities to communicate and share ideas, digital tools enable teachers to sustain a community orientation to their professional learning. Tools such as shared databases, online conferencing and discussion forums are ideals spaces for knowledge creation and connectivity.

CONCLUSION

This paper has outlined the various processes that underpin teacher learning within a broadly situative perspective based on socio-cultural views and theories of learning. Key features or affordances of Web 2.0 technologies are identified as being particularly valuable and harmonious with teacher learning, even though most of these applications were not designed originally for teacher education or even education in the wider sense: Innovative practices supported by social media provide an opportunity for teacher educators to look at wider implementation issues around technical infrastructure, but they must also address pedagogical challenges such as the integration of informal learning experiences, the limitations of existing physical and virtual learning environments and the personalisation of learning experiences. There may be a culture shock or skills crisis when "old world" educators are confronted with the expectation of working with participatory web 2.0 tools, and technologies with which they lack expertise and confidence. For these reasons, there is a need to make time for talking, awareness raising, and discussion of what pedagogic approaches and tools best support the key competencies identified by Shulman & Shulman (2004). The goal is to facilitate learning, to blend the formal and informal, to support knowledge building and distributed cognition and engagement. The affordances of web 2.0 tools and digital technologies can support the growth of a reflective learning community to enable critical dialogue and communication while nurturing creativity, independent inquiry and communication. This can be achieved by employing the tools, resources and opportunities that can leverage what teacher do naturally – socialise, network and collaborate.

THEME 5
Challenges in Higher Education

81 - University Students and Teachers International Mobility - Is it Worth?

Dana Linkeschová

[Institute of Structural Economics and Management](#) - Faculty of Civil Engineering, Brno University of Technology,
linkeschova.d@fce.vutbr.cz

Abstract: In our turbulent world there exist a number of exchange programs around the Globe. One of the most popular with the students in the Czech Republic is an exchange programme called Erasmus. The existence of ECTS (European Credit Transfer System) allows us to count the modules taken at the host university towards the student's total credit score at the home university. Another one is CEEPUS for some European countries. What has been the impact of teacher and student international mobility on educational practice and research? I think that nowadays it is one of the real challenges not only in Higher Education.

We are [witnesses of](#) changing roles of managerial work so as in education of future managers. There is more and more important initial and continuing learning not only in schools but in different enterprises as well. We are moving away from classical didactic classroom and various workshops to enquiry-based learning, E-learning and learning by doing.

In this article we can compare some numbers and graphs. The most valuable are experiences of several people who have taken the mobility chance. The extracts are based on my individual empiric research in the years 2009 - 2010. All participants are or have been students in the Czech Republic across various majors. I do hope that their own words best illustrate losses and benefits of this kind of mobility.

I am teacher in Faculty of Civil Engineering teaching future managers who are prepared mainly for Construction Companies. When I ask the question: "Who from my students has spent at least 1 month alone somewhere abroad?" I can see only a few hands up. What a pity! Today they have such a lot of possibilities. Yes, I know: Teaching and learning process in BUT has lots of obligations, which are comparable with any other Technical University at least in Europe.

I have several reasons to believe, that international mobility shall be another necessary challenge maybe the new obligation... I strongly believe that a university degree means not only gaining some knowledge and information but mainly an ability to be a strong and enthusiastic person. Or at least it shall represent some level of personal development.

After about 30 years of my university teaching I can say that a student who has spent at least one month abroad alone is usually quite recognizable. He or she had the possibility to feel and discover new emotions and learn what you cannot find in the textbooks. It is a personal way how to look at the world with new eyes.

Keywords: Learning by doing, sharing and gaining experiences in a foreign country, language and personal development, education

SOME FACTS ABOUT EXCHANGE STUDENTS IN EUROPE

We are [witnesses of](#) changing roles of managerial work so as in their education. There is more and more important initial and continuing learning not only in schools but in different enterprises as well. We are moving away from classical didactic classroom and various workshops to enquiry-based learning, E-learning and learning by doing.

In our turbulent world there exist a number of exchange programs around the Globe. One of the most popular with the students in the Czech Republic is an exchange programme called Erasmus. The existence of ECTS (European Credit Transfer System) allows us to count the modules taken at the host university towards the student's total credit score at the home university.

Erasmus

"The ERASMUS programme is targeted at higher education institutions and their students, teachers and other staff and also at enterprises and other representatives of working life. The ERASMUS programme encourages students and staff mobility throughout Europe and promotes multilateral cooperation between higher education institutions in Europe and between higher education institutions and enterprises." [1]

The Erasmus programme is offered to the students since 2007 (before it was Socrates/Erasmus programme from 2000 to 2006). In the Czech Republic there are the programmes coordinated by NAEP (National Agency for European educational programmes).

Erasmus programme participants

The Erasmus programme is not offered only to students. The universities across Europe are keen to host research assistants and tutors as well. In the table below we will show the number of participants of the Erasmus programme coming in or going out of the Czech Republic.

Table 1: Total number of students and staff mobility in Europe in 2008/2009 ([2], [3])

	Total number of students (studies and placements)	Percentage of Europe's total student mobility	Total number of staff (teaching assignments and staff training)	Percentage of Europe's total staff mobility
Czech Republic	6 045 students	3,0%	2 580 staff	7,1%
Germany	27 894 students	14,0%	3 134 staff	8,6%
Spain	27 405 students	13,8%	3 695 staff	10,2%
Hungary	5 945 students	3,0%	1 147 staff	3,2%
Belgium	4 057 students	2,0%	1 224 staff	3,4%

The previous table shows us the mobility in the past year (the data from 2009/2010 are unfortunately not yet publicly accessible). The below shown graphs are indicating the trend of mobility within Erasmus and Socrates/Erasmus between the years 1998/1999 and 2007/2008.

Graph 1: Erasmus student mobility trend in the past 10 years [4]
Graph 2: Erasmus staff mobility trend in the past 10 years [4]

As it can be seen on both of the graphs, the interest for the exchange is rising each year. However, it is not easy for a student or a staff member to actually participate on the exchange programme and there are many difficulties. Some of them are mentioned in chapter 3 with the specific students and teachers experiences.

How Czech universities mobility stands within Europe?
In the table bellow, from the European institutions that are sending out or accepting students, top 5 and some Czech are listed in the order of the number of exchange students either way.

Table 2: Top institutions for incoming / outgoing students in Europe ([5], [6])

WHY GO ABROAD?

I strongly believe that a university degree means not only gaining some knowledge and information but mainly an ability to be a strong and enthusiastic person. Or at least some level of personal growth (development). I have been a university teacher for nearly 30 years. A student who has spent at least one month abroad alone is usually quite recognizable. It is a personal way how to look at the world with new eyes. It is the possibility to feel and discover new emotions and learn what you cannot find in the textbooks. For example "By respecting our differences we learn how to appreciate ourselves as well as honour other people. Because we see things differently both of us can be right." [7] By my own experience, mobility is one of the most effective methods to get much more than only study experience.

THE CULTURAL SHOCK AND ACCULTURATION

Meeting of different cultures bares with it the problem of a "cultural shock". The most common environment for those are either working or studying long term exchanges in between countries. It is important to realize, that the worker or the student himself is not the only participant in this exchange, but often his family members or children, if travelling with him.

A temporary residence abroad and a different culture environment is a stressful situation for a lot of people. Cultural shock may be a cause of psychosomatic problems (fatigue, headache, increased necessity of sleep...), depressions, fear, squeamishness, aggression and defiance. Some people are coping more successfully than others. The intensity can vary in every household, the magnitude of the differences and the length of the stay. Some of the less flexible and adaptable individuals may not even adapt at all and they simply refuse the foreign culture. However most of the people will go through the culture merging process, which is also known as "acculturation". The stages of the culture shock can be the following:

- pre-stage – the time before departure
- "honeymoon" – take place just after arrival, in the first moment, the reactions are positive and the individual is full of expectations
- culture shock – the negative perceive of the changes and possible symptoms
- progressive adaptation to the foreign culture environment
- full adaptation – the stage of acculturation
- the return shock

The issues and themes of intercultural education, intercultural management, international diplomacy, cultural shock etc. is the topic of "intercultural psychology" discipline.

SOME EXPERIENCES OF THE PEOPLE, WHO HAVE TAKEN THE CHANCE

In this chapter I want to share experiences of several people. The extracts are based on my individual empiric research in the years 2009 - 2010. All participants are or have been students in the Czech Republic across various majors. I do hope that their own words best illustrate losses and benefits of this kind of mobility.

BSc. et MA. Luděk Knittl – University Teacher

"It is difficult to imagine NOT having foreign exchanges for students and teachers alike... I can see many positives in spending time on a foreign exchange for anyone. For my students, this is often the first time when they can experience a foreign country from the point of view of a "local" rather than a tourist. Setting the issue of the language they are going to improve completely aside, there is a variety of challenges facing anyone who has being plunged into a different cultural and social environment. From trying to find one's way to accommodation and working out how the timetable works, to negotiating with teachers, administration staff or even a bus driver. Before our students go on their "year abroad" their focus is usually primarily on the language, however, they very soon find out that they are learning much more. Extending this... They do things differently. Well, this is exactly what our focus should shift to: doing things differently. There are certainly things we observe at other universities abroad that will not work for us back at our workplace but there just might be something that could potentially improve our work and, in turn, the student experience. And even if we come to a conclusion that there is nothing new or inspiring that we can implement (and I doubt that this would ever be the case), at least we can confidently say we have learned this first-hand.

I would encourage everyone to give a foreign exchange a go. Having experienced life and work in a foreign country's university, I personally feel that my horizons are much broader than ever before. As for my students, when they come back from their stay abroad, they are aware of a number of new skills they have learned and that they then bring into their further study but also into their future careers."

MgA. Michaela Plachká – AMU graduate, maternity leave

"(...) These experiences had a lot of benefits for me. From the professional point of view: I compared my own creative work with foreign authors and I saw it in a wider context. As well I have used the archives and music libraries which are bigger than in the Czech Republic. I visited a lot of concerts with composition unknown in Czech Republic and I was inspired by the enthusiasm for contemporary music. As to the language skills, it was an important benefit especially in the sense of direct communication and understanding. From the social side: learning of different mentality; new professional and personal contacts which I see as a big enrichment and investment for the future; contact with non-post-communistic society and faster friendly relations without barriers.

Apart from those above, my interest for the country increased and I gained a deeper understanding of its culture. And last – my personal growth: mental refreshment and improvement of my memory; improvement in self-reliance; training in proactivity; revaluation of my opinions, way of thinking in different fields of life; revaluation of my own possibilities, aims and goals; betterment of searching information; I came to realize the responsibility for my life; Inspiration."

Mgr. et Mgr. Karel Ouroda, Ph.D. – University Teacher

"Thanks to all the proclamation I have anticipated, that it will be easy... The only thing missing – the agreement between the universities... I have arranged all the necessities with the relevant people, I wrote the agreement, got it translated into English and both copies checked by the legal department. As to the formal side – everything was OK. It has been sent to the foreign university – but nothing has happened. How can you leave some ten thousand km away, if you are responsible for an EU grant worth 7 million CZK, a number of unfinished theses and all the other work that needs to be supervised in person thanks to the student mentality? (...)The biggest problem was to obtain the permit from the old employer for the new one and on top of that – I was responsible for all the substitute tutors for the time being.

A few weeks of medical examinations followed. Fortunately, everything went smoothly, but none of the doctors has given me the appropriate documentation or certification. Abroad, no private doctors are accepted, everything must be from a state hospital with the result confirmed. So after the arrival – the whole jazz again – multiple screening, blood samples, etc. And what have I learned? "Never give up. No matter what!"; "It is necessary to work on your own personal development, don't always sacrifice for others."; "The only thing you have is the one you have done yourself."

Recently, I have cooperated with local professionals and nowadays a book is being prepared. I am publishing articles, visiting sights, meeting new people – for the past few years – I didn't time for that back in Brno. On top of that I got to know, (...) who is a friend and who was only pretending to be... and the price paid: One yearly salary at the university – but that's not the issue. The ten-year preparation and facing the nearly-lost hope... As one wise man has said, "Three years of hard work – ten thousand years of happiness". I am looking forward to my return and I hope that no one else will have to improve his qualification facing the obstacles I have had. And above all I will succeed in developing cooperation in my field of study, that didn't exist before"

Bc. et MSc. Klára Marečková – Ph.D. student

Studying abroad is like a long experiential learning course. It's a decision to explore the jungle of life and let it become your big adventure. Being open and having courage will enable you to cross boundaries between countries as well as the boundaries in your mind: Turn a page, follow your bliss and doors will open for you that you never knew were there before.

My own study abroad started with one big loss: The loss of my horse, followed by the loss of my boyfriend and dreams. I felt terrible - angry, grumpy, and lonely. I needed to turn a page and go somewhere far. Oh, that's it - somewhere far! Travelling - wasn't that what I always wanted to do? Something I've never done though because of all our trainings? Let's study abroad! Now!

The earliest deadline for a study abroad was coming just in three days. It was an International Student Exchange Program (ISEP), a network of 300 colleges and universities from 42 countries around the world, advertised through the Centre of International Studies at Masaryk University. I wanted to improve my English and therefore the US became the country of my choice. I've spent my weekend searching through the websites of US universities till I chose and ranked 10 of them. The last step was to get a bunch of signatures on Monday morning and submit my application before 5 p.m. All went smoothly and couple of weeks later I've received a message that my classes at East Tennessee State University start on 23rd August.

My first flight ever and there I was, in the sunny and beautiful region of Great Smoky Mountains. There were plenty of parties and trips organized by the university at the beginning of the semester and everybody was very friendly and helpful .The year of my life has started. It was only a few weeks after the semester start when I got a part-time job at the Office of Career and Internship Services. Other international students became my family and several unique friendships with Americans made my time an unforgettable experience. I took overload of classes and used every opportunity to travel. My motto was: "I'm international, I want to see everything!"

Going abroad taught me to detach myself from the sense of ownership and to realize I'm a guest. I've started to explore this generosity and felt happiness – from the nature, new friends, and the little things of life. I felt a privilege to be there and that's why I was trying to do my best. I've learned to live my life and realized what does mean to love my home country, family and friends. I felt like a year abroad gave me so much that I've decided to study abroad even the following year. I did a master program at the University of Nottingham, UK. I'm doing my PhD in Toronto, Canada now and I'm still in the flow.

This is my story. Yours is completely different. But the point is: Got an idea? Does it seem crazy? Do it!

Ing. Helena Foltýnková – PR Account Manager

Having the chance to study abroad has been the only "real life experience lesson" that I had during my 5 years of University studies. And I bet it would be the only one I will remember and profit from even years after...

I have attended a study semester in Austria during my fourth year of University. It has been the last chance that I had before I graduate and I took the chance even though I think it could have been even better benefit if I travelled abroad sooner. Many of my colleagues at the University didn't have the courage to go and they regret it all ready. But was it really such a hard decision to make?

Studying abroad is of course a challenge. But as soon as you make the decision to go the worst is over. It is the biggest "but" on the way and as soon as you have this solved out, everything else should be much easier. There are many positive reasons to go - your CV begins to be more attractive for employers, you try to live by yourself in a different environment, you improve your language and your networking. Once, one of my very senior colleagues at DHL said: "life is all about networking". She was right.

I know that everyone who takes the chance is all ready a winner. There will be obstructions on the way but you will always remember the positive. And what's worse - there might not be any other chance later. You will have your careers, your families, your loans and your responsibilities. Benefit from what is now being offered to you and take the chance! It is your investment in the future...

Bc. et Mgr. Darina Čejková – PhD. student

"As everything, living beyond the comfort of your homeland has its own pros and cons. When I arrived to the US I was full of fear, especially about my language skills. In the first four months I hardly recognized the words I had learned at school. Communication, especially through the phone was terrible. (...) The Americans never correct you, they are very professional in the business and service fields and try to understand and serve you. What about our behaviour to foreigners? I also never heard from Czech folks that science is useful, many Czech people think it's just wasting of money. (...) Many things are solved only through email, especially at work. After work the Americans spend their spare time among themselves, it's very difficult to improve English very fast.

The start of a "new" life brought mind cleaning to me. I had to think about my stuff, my life and all the troubles from home, work, school etc. were so far. Finally, I had time only for myself. I think when not disturbed or surrounded by friends, family, I had to face up to all my good as well not as good qualities. I do believe I have been learning to improve on the bad ones, because there is nobody else to hide them. Thanks to luck (God?) I stay so far away, that there is no easy way to hop on a plane or a train and get back to the home stereotype and safety. The decision of a year-long stay means a real decision, including the price of air-tickets and a 12-month rent."

Ing. Ondřej Malovaný – BUT graduate

"Student mobility as another professional working experience abroad can enrich you in many aspects: One of the aspects of studying abroad is to gain knowledge of foreign language. When you study abroad you use foreign language in every day communication among your schoolmates, friends and you use it in the most natural way.

The majority of the biggest construction companies in the Czech Republic are likely subsidiaries of foreign companies nowadays. At certain level of management the foreign language is often used. In the near future the cooperation might be more intensive. It is possible that you will have to work with project documentation, do financial reports or deal with corporate regulations in a foreign language.

(...) It is important to experience cultural differences. Every country has a different culture, which is related to the way of living (historical and geographical conditions), communication, economical effectiveness and development. (...)You can experience different systems and attitudes both in education or work, evaluate them and gain the best of it. You might change some points of view on our country after living abroad."

Bc. Jana Nováková

To succeed in today's world, it is essential to be adaptable and to differentiate you from the others. International experience is definitely one of the ways, how to achieve both. Therefore I have been Au-pair several times and considered the Erasmus program a must. I was looking for a new, non-English challenge and I stated to learn French. I remember all the worries I had. Studying in a foreign language, all the paperwork which needed to be done… But I knew that when working hard, I will make it.

But in the end, the Erasmus program was like a vacation, compared to the experience that followed. I always wanted to be more specialized, but in the Czech education system, I knew that I will finish five years later

with the same major. In France, the system is different. I decided to trade my Czech studies to French and obtained a diploma in international HR management.

Being a regular student abroad is something very different. In addition, in France, a 6-month traineeship in a company is mandatory in order to validate your studies. That year was the most difficult of all. No hobbies, limited contact with home, all the foreign environment – basically a lot of work and nothing much else. But it did pay off. Due to the traineeship experience, I really discovered myself, my strengths as well as my weaknesses. Since then I have found a new job with responsibilities in the field of Human Resources, and time to time I am also responsible for a trainee.

What all these international experiences have taken me? And what are the gains?

When I come home, the people, who have never been abroad, think "that it is easy, if you know the language". The contrary is true, even if you know the language very well, it is difficult indeed. You are a stranger. If you don't look for and don't try to make friends, nobody will go towards you. You will be alone. Even if you make friends, you can't replace the friendships at home. In some way, I lost my friends in the Czech Republic. I don't really loose them, but when I speak to them, I have no common issues to discuss. The problems they have are not really problems from my point of view. Today, I have no home country; I am a stranger in France, but also in the Czech Republic. But on the other side….

I have learned two foreign languages on a professional level and discovered how the culture is influencing the work environment. I am more open-minded, I adapt easily to new situations and I communicate much more to prevent possible misunderstandings. Abroad, you're basically starting a new life which gives you an opportunity to do things what you'd have never done before. Today, when solving problems, I look at the problem from different perspective. These international experiences gave me an opportunity to learn things that I simply can't learn at home. I became a different person, independent, self-confident and more assertive, for instance. I'd have never found a job with responsibilities at my age, if I would not go to England couple years ago.

There was a life "before" and "after" an international assignment. It is really difficult to express by words what I feel; only people who lived abroad can really understand...

CONCLUSION

I agree with Luděk who said: "I would

 encourage everyone to give a foreign exchange a go. Having experienced life and work in a foreign country's university, I personally feel that my horizons are much broader than ever before. As for my students, when they come back from their stay abroad, they are aware of a number of new skills they have learned and that they then bring into their further study but also into their future careers." Helena added: "I hope that everyone who takes the chance is already a winner. There will be obstructions on the way but you will always remember the positive. And what's worse - there might not be any other chance later. You will have your careers, your families, your loans and your responsibilities. Benefit from what is now being offered to you and take the chance! It is your investment in the future..."

I am very grateful for having my own experiences abroad. I do hope that one day mobility will be a compulsory part of the university study. I think that we can pump all the goodness from this source because we have to support the professional development and various competences to our future managers, practitioners so as their teachers, mentors and trainers.

107 - Educational Policies in Brazil and Portugal: *The Local Government*

Martha Abrahão Saad Lucchesi

Associate Researcher: in Center for Public Policy Research - NUPPs – (Higher Education),
University of São Paulo, Brazil.
mgrlucchesi@uol.com.br

Abstract: The overall objective of this study[128] is to establish a possible comparison between authors from Portugal and Brazil, regarding the policies of transferring responsibilities from the State to the local (municipal) level. The specific objective of this paper is, following a theoretical analysis, to enter the data already collected on municipal institutions of higher education (IMES) in the State of São Paulo, showing that they are spread throughout the interior of the state in midsize cities (education at the local level). The expansion of higher education necessarily involves municipal (communal) teaching, at least in countries with a large territory like Brazil. These institutions have the advantage of being linked to issues of research and teaching needs in the region where they operate.

Keywords: autarchy, higher education, communal

INTRODUCTION

Education and urbanization are words which are historically and essentially linked, because formal education, as it is known today, has always taken place in the cities. Since ancient times, it was major cities like Athens that gave rise to prominent research centers. In this context, some cities stood out as centers of production of knowledge, as was the case of Alexandria. In the Middle Ages, the history of European education was characterized by the first universities, which came into being in cities such as Bologna, Heidelberg (1386) and Paris. In the nineteenth century, the German university emerges as a model to be followed by the Americas: bringing together teaching and research in one and the same institution to produce and disseminate knowledge. In comparison to Europe and the Americas, Brazilian university emerged much later.

In Brazil, the first higher education courses were only created in the nineteenth century and until 1930 they did not include universities. The first Brazilian university to be effectively institutionalized was the University of São Paulo, founded on January 25, 1934, integrating existing autonomous colleges in the city.

Only in the 1950s were the first municipal higher education initiatives recorded. "Overcoming this condition and catching up with a historical backlog in higher education is a constant challenge for the Brazilian State, because education is the basis of the continuing process of economic development and social justice that the country is seeking." (Lucchesi, 2010b, p. 2)

The expansion of Brazilian higher education is articulated by an effort towards modernization which began with the Kubitschek[129] Administration. It is against this background that the Municipal Institutions of Higher Education emerge. With the 1961 National Educational Bases and Guidelines Law (LDBN) and subsequent legislation, the IMES proliferated in various legal formats: autarchies, public foundations and private foundations. For their maintenance, they counted on public (municipal) resources and, in many cases, on the tuitions paid by students, which were only prohibited by the 1988 Constitution.

The overall objective of this study is to establish a possible comparison between authors from Portugal and Brazil, regarding the policies of transferring responsibilities from the State to the local (municipal) level.

The specific objective of this paper is, following a theoretical analysis, to enter the data already collected on municipal institutions of higher education (IMES)[130] in the State of São Paulo, showing that they are spread throughout the interior of the state in midsize cities (education at the local level).

---

[128] This survey is part of a larger post-doctoral project on the IMES, which was carried out at the University of São Paulo Public Policies Research Center,2010. Thanks to the Fundação de Amparo à Pesquisa do Estado de São Paulo (Fapesp) for funding this project: nr. 2008/09712-5. Available at: www.fapesp.br. Retrieved: Feb. 2, 2011

[129] Jucelino Kubitschek was elected President of Brazil in 1955.

[130] In this paper, the IMES comprise all institutions created or transformed by municipal law, regardless of legal category, and supervised by the São Paulo State Board of Education.

The key questions discussed are: Can the theoretical approach of Brazilian and Portuguese authors demonstrate the relevance of *local government* in education? Currently, how important are municipal institutions of higher education to the *local government* and their move inland in the State of São Paulo, Brazil?

Linking national and local experience with the international theory that addresses this issue, as its theoretical framework, the survey took into account studies conducted by the following authors: Neto-Mendes (2004), Fernandes (2003), Souza (1999) on decentralization of education in Portugal;Di Pietro(2009), Lucchesi (2002, 2009, 2010) on an analysis of the Constitution of the Federative Republic of Brazil and Law 9394/96 - National Educational Bases and Guidelines Law -, in addition to a documentary analysis of Reports by São Paulo's State Councils of Education in order to describe regional and local authorities with regard to Municipal Higher Education.

Portugal's contribution, which in the opinion of Neto-Mendes (2004) "demands attention to the historical process of state building and its relationship with the 'peripheral powers' (the *local* and the *regional*) on the one hand, and, on the other, the current political, social and economic conditioning factors of global society governance", a contribution which will make for a better analysis of the local situation of municipal higher education in the State of São Paulo, Brazil.

MUNICIPALITIES AND AUTARCHIES: PORTUGAL'S AND BRAZIL'S PERSPECTIVES

Currently, from a European perspective, Portugal may be compared to Brazil regarding the policies of transfering responsibilities from the state to the local (municipal) level. Although much more sparsely populated than Brazil, "Portugal has, as it is known, the legal instruments which grant the local government an important and inequivocal status, simultaneously ensuring its political, administrative and financial autonomy: the Constitution, the Local Finance Law, and the European Charter of Local Autonomy created by the Council of Europe, signed by Portugal among other countries in 1985 and ratified in 1990. " (Martins, 2001, *apud*, Neto-Mendes, 2004). And it is still Neto-Mendes (2004) who addresses the role of local autarchies in public administration.

Fernandes (2000) relates the intervention of municipalities in education with the role assigned to them and also to schools in designing a democratic state, which the author considers specific and not the only possibility. In his opinion "within a certain conception of democratic state" there is a place granted to schools and to the municipality "in all state institutions and in that case, municipal intervention in education would be appropriate." (Fernandes, 2000, p. 33).

For Silva (2006, p. 48), autarchy comes from the Greek etymon meaning "self-government, self-direction." Legally, in Santi Romano's classic definition, it consists in the "ability a public body has, regarding the State, to manage its own interests by itself " (Moreira, 1997, p. 67 *apud* Silva, 2006, p. 48). Local autarchies are public bodies that enjoy that autonomy under present law.

Many of the IMES in the state of São Paulo, Brazil, are municipal autarchies. Although the two concepts are not exactly equivalent, since the two countries are distinct national states, they are similar in some respects, especially with regard to state education. Neto-Mendes quotes Martin (2001, p. 18), who states that currently the concept of democracy is linked to the idea of decentralization of power and it is in this context that the importance of the local autarchy emerges. The author claims that the decentralization of power (and hence of education) is part of a very broad discussion about the redistribution of power in the modern State. In Portugal this decentralization must follow the Constitution of the Republic, being also regulated by the Local Finance Law, which specifies a framework of duties and responsibilities. Neto-Mendes notes that the balance of forces between local power and central power is not static, rather it sets a dynamic and, of course, political process.

Portugal is also a signatory of the European Charter of Local Self-Government, established by the European Council, signed by Portugal in 1985 and ratified in 1990.

In Brazil, due to its vast territory, the development of local government has a long history, also because it was quite difficult for orders issued by the central government to reach certain remote corners of the country. In the late twentieth century, when the development of communications had already contributed to solve this problem, the 1988 Constitution of the Federative Republic of Brazil, by political choice, reassured the importance of the municipality as locus of power. It should be noted that since the Republic was proclaimed in 1889, Brazil has adopted a federative system in which each state enjoys a certain amount of autonomy and specific laws, as well as a State Constitution, a governor elected directly by universal suffrage and a State Legislature with members representing each region of the state.

According to the doctrine established under Brazilian law, autarchies are legal forms of indirect rule and, therefore, linked and submitted to the government, but they enjoy certain autonomy. They can be federal, state or municipal.

The Constitution (1988) provides in art. 37, XIX: "only by means of a specific law shall an autarchy be created and shall a public company, a mixed capital company, and a foundation have their creation authorized, it being necessary, in the latter case, for a complementary law to define the scope of action" (Brazil, 1988).

Autarchies are created by law, like many IMES in the state of São Paulo. They have their own legal status, capacity for self-government and are specialized in their purposes and activities, while this activity – higher education –, in the case of the municipal institutions envisaged in this study, is subject to control or supervision of the State so as to prevent them from deviating from their goals.

In Brazil, decentralization has a general regulation: The1996 National Educational Bases and Guidelines Law, in art. 8, provides that "the Union, States, Federal District and Municipalities shall collaboratively organize their educational systems," when it establishes the responsibilities of the States and the relaxation of regional and local public policies.

Comparatively, the issue of decentralization in Portugal and Brazil presents some similar aspects but others are quite different. This is because formal education in Portugal enjoys a much older tradition than in Brazil. Tradition is a positive aspect when it highlights the importance of education in society, but it can also be an obstacle to change. In the case of Brazilian IMES, they arose and proliferated when Brazil needed higher education and this existed only in some state capitals. In the case of Portugal, Neto-Mendes (2004) states that the issue of decentralization of powers is not limited to the participation of municipalities in educational administration. In his view, regionalization, which is foreseen in Articles 255 to 262 of the Portuguese Constitution, is still in debate, and this, in practice, affects the distribution of power to municipalities. In any case, the legislation only partially explains the dynamics of local government, including what regards municipal participation in education.

Levy (1997, p.51) states:

> The role of *local government* varies in each period of time and circumstance, according to the actors who participate in setting the political scene and the functions performed by the State in which that *local government* (emphasis by author) is inserted.

In Portugal the municipality attends preschool and elementary education, and more recently, professional education, but it has been recognized as an educational agent since 1996. "The approval of the Basic Law for the Education System has imposed a new orientation when it achieved, as the system's organizational principles, the decentralization of the structures and of the educational activities, '*so as to provide a proper adaptation to the realities, a strong sense of participation by residents, an appropriate insertion in the community and efficient decision-making levels*' (article 3, paragraph g)" (Almeida, 2004, p. 6) and "*for the creation of pre-school education establishments (art. 5, Nr. 5), the development of educational activities in the realm of special education (art. 18, nr. 6), in vocational training with the development of protocols with autarchies (art. 19. nr. 6, paragraph b) and in non-school education (art. 23 nr. 5)*" (Almeida, 2004, p. 7).

According to Grilo (1996, p. 11 *apud* Silva, 2006, p. 70) a new phase of municipal intervention in education began with the *Educational Pact for the Future*, which features among its nine objectives the goal to "modernize, regionalize and decentralize the administration of the education system" (Grilo, 1996, p. 11). The first of the ten commitments for action under the Pact is: "*to decentralize educational policies and transfer responsibilities to local authorities*." To accomplish this decentralization proposals have been made for "*a territorial rearrangement of levels of government intervention in the management of the school network*", and the "*transfer of powers and responsibilities to local authorities in the field of infrastructures, of social action of the intersectorial coordination of social levels and types of training, of socioeducation enhancement and curricular complementation, at the preschool and basic education levels.*" At last, Local Councils of Education are supposed to become more dynamic and the value of autarchies is to be recognized as local education partners.

One must agree with Silva (2006, p. 59) when the author states that the municipality has long ceased to be seen as merely the local representative of central power, but it is still a long way from being accepted as the representative of local needs. In Silva's view, it is still necessary to modify the legal political framework so that local autonomy becomes a fact, because the "transfer of duties, responsibilities and means" to the autarchies has been very slow so that it will still take sometime before their objectives can be reached. For Lucchesi (2002, p.51) "the reverse of globalization is the strengthening of ties between closer and smaller

communities. The municipality will be more important than the nation in the twenty-first century. This will pave new ways which may be positive for future society."

According to Touriñán López (2004, p. 35), strengthening the ties between closer and smaller communities is the opposite of globalization. He calls this movement of promoting local culture "glocalización" and it consists of what allows people to keep their identity through culture (Lucchesi, 2009, p.4).

METHODOLOGY

This survey was conducted with the data available, collected and organized by the CEE-SP and published in 1999, and the national data which are updated annually by the Ministry of Education. These were compared with each other and complemented, demonstrating the distribution and relevance of municipal institutions of higher education.

There are differences between the criteria of the State Board of Education (CEE) and those of the MEC / INEP in the classification of the municipal institutions of higher education, as the CEE-SP (São Paulo State Board of Education) includes all institutions that were founded by municipal law, and are supervised by the CEE, regardless of their present legal status, while INEP classifies as private the IMES that have chosen to be private law foundations, because the 1988 Federal Constitution prohibits public institutions to charge tuition.

Given this divergence, the study was based on the IMES list of São Paulo's CEE, adding further data collected from MEC / INEP, to generate a database that would come closer to present reality and allow for the preparation of tables and a more accurate analysis of the data.

In the quantitative survey, the gathering of information was continuous and the data were compared during the period studied (1999 to 2007), namely, the data on the number of institutions, types of courses compared to the total number in all higher education in the State, enrollment data, number of students beginning and concluding courses, location of the IMES, all resulting in unpublished new data. This is the frame of the broader research which aims to portray the situation of the IMES in the state of São Paulo, in the transition from the twentieth to the twenty-first century.

Municipal Institutions of Higher Education in the State of São Paulo (IMES): the survey.

The IMES: legal categories

For Maria Sylvia Zanella Di Pietro (2009, p. 422-423), the State may need to create legal entities to carry out indirect administration, and yet, despite being private corporations, they have almost all the characteristics of public entities. This is justified because their existence depends on the needs and goals of the State, which creates an institution to perform a certain activity which is actually the State's responsibility, among such activities is education.

In Brazil, since the 1988 Constitution, elementary education is the responsibility of the municipality, secondary education rests with the States of the Federation and higher education is the responsibility of the Union. However, other federal entities are not prevented from setting up educational institutions that are not within their specific competence. The case of municipal institutions of higher education is very peculiar because they appeared while other constitutional charters were in force.

The municipal educational institutions have gone through several phases in their history with regard to legal aspects. Prior to the 1961 National Educational Bases and Guidelines Law (4024), they were created and accredited by federal decree, as was the case with the other institutions of higher education in Brazil. After 1961 and until the promulgation of the 1988 Constitution of the Federative Republic of Brazil, the IMES were able to proliferate in various legal formats: as autarchies, public law foundations, private law foundations, but always created or transformed by municipal law.

A foundation, when created by the government, has a patrimony that is totally or partly public. Its legal status can be either private or public, as accorded to it by law, but its goals are mandatorily public. When it enjoys public status, it resembles an autarchy, and is even called a "foundational autarchy" (Di Pietro, 2009, p. 425).

The creation of local authorities meets the need to decentralize public administration, making it more agile, as highlighted by Decree Law 6016 (Brazil *apud* Di Pietro, 2009, p. 429).

Autarchies can serve several purposes (economic, industrial, corporate, social welfare), among which education and culture stand out, thus including universities (Di Pietro, 2009, p. 430).

The Brazilian concept of autarchy differs from the Portuguese and European concept in general. Sá (2000, p. 22) and Silva (2006, p.47) consider that the countries of Western Europe and Central Europe share many similarities with regard to regional and local distribution of power which characterize local autarchies.

Although there are differences from one European country to another, all autarchies arise from a pluralist and participatory view of democracy. For that reason, in 1985 the European Charter of Local Self-Government was drafted; it extends the role of local autarchies in democratic states, prizing the principle of local autonomy, which is already recognized by the Constitution in Portugal. According to the Charter, a local autarchy consists in the "right and [in] the effective capacity of local autarchies to regulate and manage, under the law, under their responsibility and in the interests of their respective populations, an important part of public affairs" (point 1 of article 2) and "necessarily implies that this public entity should be based on decentralization, self-administration, self-direction, self-management or self-governing of communities located in a territory. Paragraph 2 of article 2 of the same document stresses the importance of local power in democratic regimes, as it allows citizens to have a more direct participation in the management of public affairs that concern them, because the administration becomes closer to the citizen and at the same time more effective.

Maria Sylvia Zanella Di Pietro (2009) argues that in the case of private-law legal entities, i.e. ones "created by an act of Government", "**private law is partially repealed by norms of public law**" (p. 425). [emphasis by the author]

The table below shows the legal categories of IMES in accordance with the State Board of Education of São Paulo's legal acts authorizing their operation.
Source: CEE 2007
Chart 1: Administrative Categories on the Legal Act of The IMES SUPERVISIED by THE CEE-SP

The IMES can be organized into four administrative categories. The chart shows a preference for Municipal Autarchy, followed by Private Law Foundation. Both are forms that offer greater administrative autonomy. Autarchies, being the model that best serves the interests of the institutions, add up to almost 50% of all IMES.

The parameters that categorize whether an Institution of Higher Education is public or private cannot rely on mere conceptual interpretations or policies; the only way to do this is by legal provision, according to Brazilian law.

The Relevance of IMES in the State of São Paulo.

The expansion of higher education necessarily involves municipal (communal) teaching, at least in countries with a large territory like Brazil. These institutions have the advantage of being linked to issues of research and teaching needs in the region where they operate. In parallel, they need to be inserted into national and international networks of research, otherwise they will not be able to fulfill their role as institutions of higher education.

According to Lucchesi (2010a, p.10), "The sub-system of higher education in Brazil is constituted of universities, university centers, integrated colleges and colleges or individual institutions." Some IMES in the 1999 - 2007 period acquired another status as Integrated Colleges, University Centers or Universities.

The institutions of higher education have been motivated to change their academic category under pressure from the very system and also from the market which has become more demanding; in these disputes higher education loses its character of "**public asset**". The competition for students seems to be more intense, and the autonomy to create new courses is shown in the intentionality of the action; every year there are new courses in the institutions of higher education, although one can not prove their geoeducational necessity. However, the change is taking place, because "a new educational project and even a new law will only succeed when it sets aside the legal aspect and enter the field of culture (Lucchesi, 2002, p.101).

Nevertheless, the IMES of the state of São Paulo continue to be predominantly individual institutions of higher education.

In 2007, the São Paulo State Board of Education supervised 34 IMES.

Table 1: Comparison Between the Number of Students in Federal, State and Municipal Institutions of Higher Education with Data from INEP and CEE-SP [131]

YEAR	STATE		FEDERAL		PRIVATE		IMES		TOTAL	
	N	%	N	%	N	%	N	%	N	%
1998	69.422	10,23%	6.609	0,97%	555.949	81,91%	46.726	6,88%	678.706	100
1999	53.078	7,26%	6.754	0,92%	618.698	84,58%	52.992	7,24%	731.522	100
2000	50.629	6,26%	7.114	0,88%	692.751	85,70%	57.841	7,16%	808.335	100
2001	49.347	5,56%	7.358	0,83%	767.536	86,49%	63.207	7,12%	887.448	100
2002	65.108	6,69%	7.570	0,78%	830.846	85,40%	69.369	7,13%	972.893	100
2003	68.458	6,67%	7.832	0,76%	876.128	85,31%	74.592	7,26%	1.027.010	100
2004	68.838	6,38%	7.729	0,72%	919.790	85,22%	82.964	7,69%	1.079.321	100
2005	71.036	6,18%	7.687	0,67%	985.102	85,66%	86.196	7,50%	1.150.021	100
2006	73.840	6,00%	8.111	0,66%	1.065.820	86,61%	82.844	6,73%	1.230.615	100
2007	78.691	6,02%	10.139	0,77%	1.139.828	87,15%	79.210	6,06%	1.307.868	100

¹ Excluding enrolment in Centers of Technological Teaching (CET) and Technology Coleeges (FaT)

The enrolments in "IMES" includes Private Law Foundations created by Municipal Law and Supervised by CEE.

Source: INEP e CEE/SP

The IMES, percentage-wise, show numbers that are slightly below those of the state institutions[132] over the period 2000 to 2007, while both categories are well above the federal institutions in the State of São Paulo, but significantly below the percentage of private schools. Table 1 shows that in the last year surveyed (2007), enrollment in state institutions covered 6.02% of total students in higher education in the State of São Paulo and in the IMES, it reached 6.06%. The latter receive roughly the same number of students than the former, but their relevance to higher education in the State of São Paulo has been little noticed, because they have been poorly studied. The intense and meaningful scientific production of São Paulo's state universities brings them to the foreground not only in Brazil but also around the world (in particular, the University of São Paulo - USP), overshadowing the role of the IMES.

FINAL REMARKS

The analysis showed that the phenomenon that helped cities to become a **political arena** was the contemporary immigration of rural workers to the municipalities, which only occurred as of the mid-twentieth century, especially in Brazil.

The migration of rural populations to the cities in Brazil led to the move inland of educational centers, which arose in cities able to attract the population of the region where they are located. These were not only economical centers rather the very supply of education meant that a city became a center of populational attraction, especially of young people and qualified adults (teachers).

The IMES designed a new geography for higher education by contributing to the move inland, especially and early on in the State of São Paulo. The boundaries that restricted the Institutions of Higher Education to the Capitals of the States were displaced by initiative of the municipalities.

Local autarchies are already common in Portugal, but in Brazil, autarchies may be federal, state or municipal. In the case of IMES, they are municipal autarchies, although not all IMES have opted for this

---

[131] Table 1 was created by the author in agreement with CEE-SP's guidelines, where institutions of higher education created by municipal law, even though as private law foundations, belong to the IMES category. The data are distinct from those of MEC / INEP, but were adapted to the CEE-SP list.

[132] The table includes 1998 because that year still showed a significant difference between the IMES and the state institutions. In the following year they lost approximately 3% of their total students in the State to private institutions and almost 1% to IMES

legal status, becoming public law foundations or private law foundations. The variety of legal status that is possible for Brazilian IMES makes our educational panorama very different from what is seen in Portugal. However, it is noteworthy that this case study refers to institutions of higher education. The situation of elementary education in Brazil has another legal status as public, free and secular education, which is beyond the scope of this study, which addressed specifically the Municipal Institutions of Higher Education of the State of São Paulo.

It can be seen that this is quite a peculiar case and that the subject deserves a more thorough study as part of a fuller discussion about sharing power or centralizing it.

160 - Current Demands for Teaching in Higher Education - The Role of Students

Leanete Thomas Dotta

lea_1971@hotmail.com

Abstract: This paper is a highlight of the new demands placed on teachers of Higher Education, based on his views on current behaviors and needs of students. The central argument in defense of the article is that the new characteristics of students, described by teachers, play a fundamental role in the formation of identity and who are carriers of offers of new teacher identities. This argument is based on empirical data collected through semi-structured interviews with the trainers of teachers working in three different types of institutions of higher education in Brazil. The corpus data was subjected to categorization according to the theoretical content analysis with the aid of appropriate software for qualitative analysis - the NVivo 8. The theoretical framework used to support the analysis and discussion of the data was the identities, whereby the identity constitution results from two heterogeneous processes. The first refers to the role of identities by the institutions and agents that directly relate to the individual, the *virtual identities*. The second process is the incorporation of identity by the individual making use of legitimate categories for yourself and for others, the *real identities*. The mismatch between the two processes results in the development of identity strategies. The great **heterogeneity** student is referred to unanimously by the trainers, the latter involving mainly contrasts, especially the living in the same class of young students and older, with very few technological mastery and with prior knowledge, with special education needs, students, workers with little time to devote to studies, which make long journeys every day so they can study. These situations interfere directly in the class dynamics change and require some time-honored practices of teachers that mobilizing identity strategies can target, or the accommodation of *identity for themselves* the *identity to others*, or the assimilation of *identity to other* for *identity for himself*. Thus, students are actors as bearers of new requirements for teachers, requirements for which are often not prepared placing the student in a prominent position on the staff's initial and ongoing formation.

Keywords: Trainers of Teachers - Students - Professional Identities

INTRODUCTION

The purpose this paper is to highlight one of the new demands placed on teachers of Higher Education, based on his views on current behaviors and needs of students. The central argument in defense of the article is that the new characteristics of students, described by teachers, play a fundamental role in the formation of identity and who are carriers of offers of new teacher identities.

The considerations proposed in this paper result from some of the results of an investigation about the trajectories of identification of teacher educators in undergraduate courses. This research aims to identify and analyze the professional identities of teachers who train teachers of undergraduate courses, built on the administrative organization and academic organization institutions where they work, the disciplines they teach and the field of knowledge of the course to which they belong.

Data collection was circumscribed in the western region of Paraná State, Brazil, focusing on trainers from three types of institutions - two private colleges, a private university and a public university, undergraduate courses common to all three types of institutions, which are : Degree in Physical Education, Degree in Mathematics, Degree in History and Degree in Pedagogy. In total was due to take place twenty-four interviews – course defined by two professors from each institution, one of a specific discipline and one of a pedagogical discipline, however, since some teachers work both in specific disciplines and pedagogical and even more of a course, the interviews, the total was reduced to twenty.

The interviews were audio taped and transcribed, as a result were subjected to qualitative analysis software - the QSR - NVivo where the data was entered into previously defined categories. By categorizing the data were organized in tables that allowed readings vertical, horizontal and transverse, as well as their analysis.

To attain the goal of this article was selected category Concepts and Practices and Students in this subcategory. However the data analysis was not restricted only to the category mentioned above, since in the course of the interview as a whole, emerging data on students' conceptions.

To compose the framework reflective of this article we present some initial discussions about teaching in higher education. We also present the central themes of the theoretical framework on professional identities that underlies our reflections and methodological approach followed for obtaining and analyzing data. Following are presented the data on students' conceptions and their analysis in the form of concluding remarks.

TEACHING IN BRAZILIAN HIGHER EDUCATION

Teaching in Brazilian higher education has attracted increasing interest from researchers in the educational field. With the advent of the Evaluative State presence in Brazil (Freitas, 1999, 2002, 2003), the requirements focused on quality and excellence in teaching attracted the eye for that theme. Research groups are formed, and several researchers are mobilizing towards the establishment of the field research of teaching in higher education.

For most of these researchers, one of the strongest determinants of teaching in higher education, is the institution in which the teacher carries out its activities. The institution's mission and roles prioritized determine the type of activity to be performed[133]. In an institution, private or public, federal, state or municipal, is the organization that sets the academic thinking and practice of teaching in different ways.

Thus, according to the type of institution in which the teacher works, their teaching will suffer different constraints. If the institution you work allows you to participate in a research group, it is likely that his vision of teaching has a strong research component. If your institution acting only in the field of teaching, the condition is likely to be the teaching without research.

In the case of universities, there is a tendency that considers the professional identity built around the scientific, since teaching is an activity seen as having less prestige. According Zabalza (2004), one worrying aspect in relation to teachers in higher education is the fact of having a professional identity uncertain, since their preparation for practice has always been focused on the scientific field, an aspect that hinders the establishment a professional identity tied to teaching.

For the same author as specialized activity, teaching in any grade, includes expertise, or requires specific preparation for the exercise. Teaching is a task taken by the complexity, since it requires detailed knowledge about the specific content and how students learn, among other skills.

Considering the complexity of teaching, Cunha (2007) highlights the need for conditions of justification of actions developed, based on knowledge based on arguments and theoretically sustained. Thus, the teaching profession requires a special formation to identify the amateur status of the profession, which tends to keep the culturally-installed being reproduced every day. Definitely not enough to be a teacher with expertise in one area of expertise to bring about learning for students, first of all, it is necessary to recognize the multiple demands of work and complexity of its activity.

The professor of higher education is the only professional which does not require specific formation for the profession, which leads to bad consequences for the teaching process. The increasing massification of higher education, the reduction in investment, the new demands of the labor market, the adoption of new technologies of information and communication require revisions to current models of performance and teacher formation. It is necessary that teachers pass their disciplines for specialist teachers of those disciplines, a movement that involves specific and pedagogic knowledge, with the main objective of student learning.

---

[133] Higher education in Brazil, according to current legislation, is organized as administrative, academic and the formation as follows:
Administrative Organization
Public institutions are created or built, maintained and administered by the government: federal - maintained by the Federal Government, State - maintained by national governments, Municipal - maintained by the municipal government.
Private institutions are maintained and managed by individuals or legal entities under private law and are divided into: private for-profit institutions or strictly private, nonprofit private institutions, which may be community, religious or philanthropic.
Academic Organization
University Institutions: multidisciplinary institutions, public or private, formation of high level professionals who develop regular activities of teaching, research and extension. They are divided into universities, universities and specialized medical centers.
Non-university institutions, which can be CEFETs (Federal Centers for Technological Education) and CETs (Technical Education Centers), Integrated Schools, Colleges Isolated and Higher Education Institutes.

Cunha (2010) presents the following organization of teacher knowledge needed for teaching, related to the educational field:

- knowledge related to the context of pedagogical practice;
- knowledge of the size of the relational and collective work situations and processes of formation;
- knowledge related to the ambience of learning;
- knowledge related to the socio-historical context of the students;
- knowledge related to the planning of teaching activities;
- knowledge relating to the conduct of classes in multiple possibilities;
- knowledge related to the evaluation of learning.

The author stresses that different knowledge are likely to link with each other and are defined by mutual dependence.

The need for specific knowledge for teaching in higher education is also indicated by Masseto (1998), for whom the teacher, in addition to competence in a specific area of knowledge, you need the field on pedagogical as well as the exercise of political dimension.

Similarly, for Zabalza (2004), familiar with the discipline itself is fundamental to teaching, but not unique. Thus, besides knowing the content, teachers should be able to analyze and solve problems, analyze, describe and make content understandable to identify the best way to approach the contents of the ways to address them, select appropriate methodological strategies and resources that facilitate learning, organize ideas, information and tasks for students. The author also provides skills that relate to the character interact with the students. Therefore, instructors must know how to identify what the learner already knows, communicate clearly and friendly with students; act appropriately with the characteristics of the group of students who have to work, being able to stimulate learning, group work and thinking of them.

The author notes that different knowledge likely to link with each other and is defined by mutual dependence. The need for specific knowledge for teaching in higher education is also indicated by Masseto (1998), for whom the teacher, in addition to competence in a specific area of knowledge, you need the field on pedagogical as well as the exercise of political dimension.

Also for Zabalza (2004), know well the discipline itself is fundamental to teaching, but not unique. So, besides knowing the contents, teachers should be able to analyze and solve problems, analyze, describe and make the contents understandable to identify the best way to approach the contents of the ways to approach them, select appropriate methodological strategies and resources that facilitate learning, organize ideas, information and tasks for students. The author also provides skills that relate to the character interact with the students. So, instructors must know how to identify what the learner already knows, communicate clearly and friendly with students; act appropriately with the characteristics of the group of students who have to work, being able to stimulate learning, group work and thinking of them.

Shulman (2005) believes that restrict teaching the basic skills, knowledge of content knowledge and general teaching is to consider teaching as something trivial, regardless of their complexity and their needs.

The teaching process begins when the teacher understands what should be taught and how to teach. In the process, involved at least seven types of knowledge: content knowledge, teaching general knowledge, knowledge of curriculum, didactical content knowledge, knowledge of students, knowledge of educational contexts and knowledge of the objectives, purposes and values of education and its philosophical and historical. The author also considers that among the categories of information presented, the teaching of contents knowledge occupies a prominent place, since it represents a blend of content and didactics.

The professional knowledge of the areas of knowledge into action, the second Ponte (1993 *apud* Traldi JR, 2006), breaks down into four main areas: knowledge of the contents of education, including the relationship with other disciplines, knowledge of curriculum ; student knowledge, involving characteristics, learning forms, needs and interests, and knowledge of the instructional process, namely which refers to the preparation, condition and evaluation of their teaching practice.

The teaching in higher education is usually understood as a consequence of other activities: in the case of teachers who work in the labor market, as a result of acting in his profession, in the case of teachers who work in other levels of education, as a result of teaching these other levels, and in the case of teachers who are dedicated exclusively to working in higher education, as a result of its relationship with the research. So, teaching takes a naturalized form of exercise. Such naturalization refers to the maintenance of the processes of cultural reproduction as a foundation for teaching, in other words, the teacher teaches based on his experience as a student and / or inspired by his former teachers.

Every teachers were formed by experienced teachers and pedagogical practices of them, so absorbed world views, epistemological conceptions, political views, postures and didactical experiments. This context contributes to their formation and for the organization, consciously or unconsciously, their cognitive and affective schemas that underlie their teaching.

The intervention in this process of naturalization requires professional reflection based on the deconstruction of the experience. The practices are changed only by reflection of the subjects about themselves and about their formation, the main effect of formation of teachers, whether initial or continued.

PROFESSIONAL IDENTITIES

The theoretical framework field of identity that underlies the discussion presented here is the statement by Claude Dubar, which understands identities as a result of "both permanent and provisory, individual and collective, subjective and objective, biographical and structural, the various processes of socialization that, together, build individuals and institutions define" (Dubar, 1997, p. 105).

The conceptualization that Dubar (1997) is about the notion of identity that assumes the perspective of social identity from the combined two transactions: one internal to the individual, and another, external, established between the individual and the institutions with which it interacts. This division intrinsic - for identity itself and identity to the other - is both inseparable and at the same time, problematic. Correlativity inseparable from the identity for himself to the Other and its recognition, that is, I just know who I am through the eyes of another. And problematic because one can only trust on communication between individuals to inquire about the identity that attaches to one another and so forge your identity. Because communication with others is marked by uncertainty, can't be sure that the identity of an individual's identity to coincide with the Other. You can then conclude that identity is never pre-defined: it is constantly construction and reconstruction, a move more or less uncertainty and more or less durable.

The constitution of identity results from two heterogeneous processes: the first refers to the attribution of Identity by the institutions and agents that directly relate to the individual and can't be analyzed out of action systems in which the individual is involved, resulting relations power between all the actors involved and the legitimacy of the categories used.

The second proceeding concerns the incorporation of identity by individuals and can't, in turn, be considered outside the social trajectories by which individuals construct identities for themselves, using categories that must be fair to the individual and the group from which to define their identity-for-itself.

The two processes do not necessarily coincide. There may be a disagreement between the virtual social identity to an individual identity and social reality that it assigns. Reducing the deviation between the two identities are promoted by identity strategies, which can take two forms: a form of external transactions to the individual and significant others in order to accommodate itself to the identity of identity to others - called objective transaction, and the way internal transactions of the individual, between the need to preserve some of their previous identifications (which are the identities inherited) and willingness to construct for themselves new identities in the future (target identity), in search of identity assimilation the other-identity for self- identity - this transaction called subjective.

The articulation between the objective transaction and subjective is the key of the construction of social identities. The transaction objective set up because, in a confrontation between the demands and offers of possible identities. This is a real negotiation between those seeking an identity in a situation of openness in their field and who can offer an identity in a situation of uncertainty with regard to the proposed virtual identities. This negotiation of identity involves a complex communication process, where the quality of relationships with others is a criterion and an important challenge in the dynamics of identities.

The formation and work contexts are some of the action systems that transport proposals of identities that come into contact with the trajectories of individuals with real identities. The formation of professional identity is the result of a process of secondary socialization, namely the acquisition of knowledge related to the specialized field of activity to which it refers.

Professionally, according to Lopes (2001), highlights the relevance of the professional identity of first base or professional identity, which corresponds to a trajectory and a strategy, considering it is a projection of themselves, present and past to the present the future, putting into play the self-image, assessment of their capabilities   and   realization   of   desires.

The space for the recognition of identity is inseparable from the spaces of legitimation of knowledge and skills associated with identities. The objective transaction between individuals and institutions are organized around the recognition and non recognition of skills, knowledge and self images that constitute the core of the claimed identity (cf. Dubar, 1995 *apud* Lopes, 2001).

COURSE METHODOLOGY

The study from which data were taken for analysis presented in this article is embedded in a sociological perspective, considering the categories of analysis proposed by Claude Dubar (1997) for empirical studies in the field of professional identities.

The data were collected through semi-structured interviews that were audio taped and transcribed.

The richness that exists in communication, especially in human speech, vision allows a "polysemic and valuable" (Campos, 2004, p. 612), which allows wide possibilities of interpretation. Therefore it is necessary to search a content analysis, nor extremely linked to the text or the technique - which could undermine the researcher's intuition and creativity - being too subjective, which would bring the danger of imposing one's own ideas and values researcher intentions expressed in the speech of the researched.

Certain data about the contents of a communication has no value until it is bound - by some form of theory - to another. So, "making inference in content analysis, means not only make assumptions about a certain subliminal message, but I base them with various theoretical conceptions of the world and the concrete situations of their producers or receivers." (Campos, 2004, p. 613).

Initially the treatment of data from the interviews was conducted with the aid of suitable software to analyze qualitative data - QSR NVivo. The software used on the one hand, served to support the organization and categorization of the interviews, providing an interactive work to exploit the information contained in articulation with the theoretical frameworks used in the study. On the other hand, also enabled the cross checking of different categories, linking, parallel and simultaneously, a horizontal analysis - all the interviews, by categories, sets - reviews and vertical, namely each interview, understood in its uniqueness.

Considering the theoretical framework and methodological approach used was constructed a set of categories and subcategories, so a priori. The software allowed us to create, like a tree, a codification scheme that allows the visualization of relationships between the various categories and subcategories, as well as the establishment of connections among themselves. For purposes of discussion to which we propose in this article was elected subcategories – "Student" - housed in the category called "Concepts and Practices". The subcategory used with respect to concepts and practices of teacher educators in relation specifically to students. Another subcategory used was called "What the students think and manifest", housed in the category "The importance of being teachers in higher education". The data emerged from questions asked to the teacher educators about students the major problems encountered in their teaching practice.

The definition of the research universe, as well as the choice of subjects was based on the following parties: the administrative and academic organization of the institutions working in the trainers, the hierarchies that are established in higher education with respect to the different courses, and greater or lesser appreciation of the pedagogical disciplines and specific.

In total was planned to take place twenty-four interviews - two teachers for each course in each institution, one specific discipline and one pedagogic discipline, however, since some teachers work both in specific disciplines and pedagogical, and even more of a course, the interviews, the total was reduced to twenty.

During the presentation and analysis of data, the teacher educators interviewed will be referred to by the sequence of subject 1 (S1) subject to 20 (S20).

DATA RESEARCH AND FINAL CONSIDERATIONS

From the information gathered through the instrument of data collection, we present an overall profile of teacher educators participating in the research, taking into account gender, age and academic title.

In synthesis, we can say that the subjects in this investigation are divided almost equally between men and women, mostly aged between 36 and 45 years; In terms of titration academic, most - seventeen teachers - a master's degree, only five professors have doctoral degrees and only three teachers have specialization.

Through analysis of the worlds built mentally by individuals from their social experience, it is possible to identify the professional identities. "These 'active representations' structured discourse among individuals in their social practices 'specialized' thanks to its mastery of a vocabulary, the internalization of 'recipes' to the incorporation of a 'program' (Dubar, 1997, p.100).

Among the dimensions of such "active representations" is the relationship with language, namely the categories that the individual uses to describe a situation experienced as articulates the external constraints and internal wishes, obligations outside and personal projects requests from others and personal initiatives.

Thus, for the same author, the identity constitution results from two processes that are heterogeneous: the first refers to the role of identities by the institutions and agents that directly relate to the individual - are the virtual identities. The second process is the incorporation of identity by the individual making use of legitimate categories for yourself and for others - are the real identities. The do not correspond between the two processes results in the development of strategies that can target the accommodation of identity for

themselves the identity for other, or the assimilation of identity for other for identity for himself. These are, respectively, of the objective and subjective transactions.

The way individuals articulate the acts of attribution and acts of belonging have led the construction of specialized knowledge or professional knowledge. Try to learn this knowledge, considered as results, both biographical and relational, can give clues to how subjects articulate acts of attribution and belonging.

Reading of data has allowed us to initially view the subjects of private colleges are those that refer less to the characteristics of origin of students, three teachers speak of the situation of their students as workers, a teacher speaks of differences of age and a speech about students who discover they are in the wrong. At private universities, teachers are more detailers about the students, referring to family problems, problems of identification with the course, students are very young, "rulers" of technologies, lack of previous knowledge workers from various professions With different age groups with special needs or who live far from the university. At public universities, the teachers mention some other features: the immaturity of students, students young and active, "computer" with "historical characteristics", rather politicized, with lack of knowledge about the course, there are differences between students of evening classes and daytime, different age groups, students with little cultural baggage.

In terms of relations with the studies and the disciplines, teachers of private colleges say their students are inquisitive little bit and participatory, with some difficulties in learning, disinterested, do not enjoy studying, reading and reflecting. At private universities, teachers also say that many students have learning difficulties, are uninterested, they lack the curiosity to learn, question the importance of the pedagogical disciplines, value more the specific disciplines, have difficulty reading and writing, comprehension and interpretation texts and are unruly, but on the other hand, some of these teachers believe that students are committed and responsible. For teachers of public universities, many students are disinterested, they have difficulty reading and writing, are not in the way that would show little interest in the educational disciplines, are unruly, disinterested and not very committed, but on the other hand, some Teachers consider that "most students are responsible, diligent and interested" (S14, S15, S17, S20).

Among the knowledge to teach, according to Shulman (2005), is the student's knowledge and its characteristics. The data show that, at least in general, the study subjects have knowledge about learners and their characteristics. The characteristics of the students mentioned by the subjects, resemble that authors like Zabalza (2004), Alarcão (2001) and Anastasiou & Pimenta (2005) show in their studies.

Zabalza (2004) believes that higher education is no longer social privilege for few. While in Brazil, access and retention in education is still relatively small, the statistics show significant increases in the number of young adults entering higher education[134]. This range does not occur only in the horizontal direction - young people from different social classes and different geographical locations - but also vertically - individuals of different ages. Such a situation may result in the need of care for larger groups, the heterogeneity of the groups, in little motivation for the study, the recruitment of new teachers - not always adequately prepared for teaching - at least the possibility of more individualized attention to students.

The greater heterogeneity of students involves the fact that they have to answer the demands of others strictly geared to the objectives of the studies, as in the case of spouses and family obligations, students who work or live far from the place of study. Such situations can directly interfere with class dynamics and require special attention from teachers.

The student of higher education, according to analysis Alarcão (2000), presents to psychosocial problems - represented by the family and social rootlessness, feelings of emancipation and liberation, conflict of values in different spheres of life; methodological problems - frequent absences, acceptance of failure as normal, dispersed among too many activities and inadequacy in the methods of study. For the author, these factors impose new demands on the teaching level in question.

To that end, Pimenta & Anastasiou (2005) indicate the results of a study of 140 teachers working in an institution of higher education with six courses, predominantly nocturnal. The description of the problems perceived by teachers for students similar to those reported by the subjects of the research reported here. The authors systematized the results as follows: lack of interest, motivation or commitment to their own learning, passivity, individualism, interest on the note and pass the year and / or get degree, lack of discipline and study habits insufficient; level of knowledge or insufficient prerequisites to follow the course; difficulty in

---

[134] According to data of the evolution of higher education - Graduate - 1991 to 2007 (provided by INEP - www.inep.gov.br) in 1991, they entered through the entrance exams and other selection processes, 426,558 students, in 1995, the inflow was 510,377 students, in 2000, 897,557 new students, in 2005, enrollment was 1,397,281 students, and in 2007 were 1,481,955 students.

interpreting, writing and reading, difficulty thinking, lack of critical, high heterogeneity and diversity in each class of general maturity, lack of time to study, with little extra contact class, student-workers.

The same authors, in addition to features found in students, denounce characteristics of institutions for students, especially towards the lack of reception that have been generating some of the negative features presented by the students. The institutional organization and the teacher's practice can generate negative attitudes among students, such as:

- Lack of clarity in the area of knowledge, its epistemological universe and professional relations with the world, society, life;
- Lack of clear information on the formative trajectory that will perform and on the demands made upon them;
- Strictly targeted formative routes to courses and classes, without prospects for understanding the development possibilities for research, study in other places such as schools, cultural spaces, in general, labor camps, and no prospects for establishment of interpersonal relations and working with colleagues and teachers.

In the last three issues, linked to institutional issues, we can see many of which are implicit concepts and practices that can be observed in the data from this research. This situation is a clear indication of how the process of perpetuating some of these concepts and practices. With regard to the expectations that teachers have towards the students, It is noted from the data, that among the teachers of private colleges, are the expectations that students learn the content taught, who wish to learn, they have aware that there are no ready-made recipes, learn the content, but also learn where to find them. Faculty members at private universities, there are the expectations that students learn content, they have good performance as professionals, they are better people, and know at least how a school. Teachers at public universities expect their students to acquire the discipline that is fundamental, it becomes apparent that the chosen course is what you really want to life that are better than the teacher.

If the space for recognition of identity is inseparable from the spaces of legitimation of knowledge and skills associated with identities, the objective transaction between individuals and institutions are organized around the recognition and non-recognition skills.

To Dubar (1997), the process of seeking recognition means possible conflict transactions between individuals - who have desires for the identification and recognition - and institutions - offering statutes, category and forms of recognition. They are put in play spaces where individuals identify priority are considered sufficiently recognized and valued. Being able to play with different spaces and to negotiate and manage investments belonging is an essential element in the transaction objectively. The possibility of multiple partners in the pursuit of recognition can put space of the classroom and the students in a prominent place.

Obviously, see the student how significant other indicate conceptions of teaching and student that the teacher has. If the student is seen as a central element in the process, a subject that has an active role in defining teaching, then it is possible that it is seen as a significant other, and thus occupies the central role in maintaining the social reality of the subjects. Anyway, it is possible to assume that peer recognition is more visible and safer than the recognition of students.

In relation to what students think of teacher educators study subjects, according to the trainers themselves, the data show predominantly positive references. One subject says he is viewed negatively by students, but that's not what they say, another subject that indicates a more positive or more negative, by students depends on the discipline, or can be viewed positively in discipline and unlike another.

Among the questions that guided the interviews with the subjects of this study, some were prepared with the aim of causing the subject to clarification of the identity for himself, considering his correlativity to the other and his recognition. Thus, teachers have focused identities for themselves, specifically, to be "demanding", "committed", "hard" and "good teacher" directly linked to the other identified as the student.

The research data allowed us to identify and highlight one of the factors that can be understood as a bearer of offerings of new identities as teacher educators. Students, either by their different characteristics and require appropriate treatment by teachers, both for its central role as a significant other in identity constitution teacher. Thus, students are actors as bearers of new requirements for teachers, requirements for which are often not prepared placing the student in a prominent position on the staff's initial and ongoing training.

170 - Crafting Programs to Stimulate Student Engagement and Persistence in Higher Education

Clelia Pineda Báez

School of Education, Universidad de La Sabana, Bogotá, Colombia
clelia.pineda@unisabana.edu.co

Abstract: This mixed descriptive and interpretative study sought to identify aspects that contributed to students' engagement with their academic and social milieu in Colombian higher education settings. Responses provided in a questionnaire and interviews conducted with coordinators of retention programs indicate that students' sense of engagement is fostered when they take part in activities and projects crafted to stimulate their participation in the research and innovation agenda of faculty. Also, when those projects go beyond the classroom boundaries, students tend to engage and persist on their academic endeavors and display a strong sense of social responsibility and leadership. The results indicate that there is an imperative need to transform traditional pedagogical and curricular practices. They should be oriented towards establishing connections between the education institutions and the contexts where they are located so that all members of the academic community can actively participate in the social dynamics of their regions.

Keywords: Student engagement; higher education retention programs, teacher and student partnership.

INTRODUCTION

Promoting development worldwide requires that higher education institutions focus on guaranteeing access, equity and quality (UNESCO, 2009). Consequently, nations around the globe have begun or continue to examine their education policies and practices to improve the access of students to universities and the quality of their academic experience. Colombia has developed and implemented different strategies intended to increase the number of individuals entering the higher education field. However, student dropout rates remain close to 45% (Guzmán et al., 2009), which implies that only half of the students who enter an academic program complete it successfully. This loss of students minimizes the opportunities of development for the country as there are less qualified people to enter the workforce and increases social exclusion and inequality (Donoso and Schiefelbein, 2007). Furthermore, it has a grave impact on students' self-concept and personal life, on their families and on the universities themselves. Among other aspects, students who abandon their career experience frustration because their professional and economic aspirations become limited, and this consequently hinders their possibilities to ascend socially (Rivera et al., 2005). Families are affected not only in terms of their economic investment, but in the positioning and prestige that is usually associated to earning an academic degree (Pinto et al., 2007). Student attrition also impacts the financial stability and the sustainability of academic programs and becomes an aspect to examine in connection to the quality and effectiveness of higher education institutions (Fike & Fike, 2008).

The results of various studies conducted in Colombia to identify the contributing factors in the high rate of student attrition parallel those obtained worldwide. They are associated to financial support, mistaken vocational selection, weak academic skills that are mainly connected to critical reading, writing and mathematics, social adaptation barriers, disaffection from school, lack of academic engagement, students' degree of maturity, and reduced family support (Guzmán et al., 2009; Rojas, 2008; Rojas & González, 2008; Castaño, Gallón, Gómez & Vásquez, 2008; Pinto et al., 2007; Ministerio de Educación Nacional, 2006; Ramírez, 2002).

Higher education institutions in Colombia have proposed different programs to respond to the obstacles detected and to increase student graduation rates. They include, but are not limited to, economic and academic support programs, vocational orientation, transition programs aimed at facilitating the adaptation of students from high school to the university, and recreation, sports and cultural programs usually grouped under the label 'student welfare'. However, little is known about how those programs are functioning and the results they are yielding so that student retention policies can be formulated more accurately.

This paper describes the findings of a study carried out by a group of researchers from the School of Education at Universidad de La Sabana in Colombia that sought to identify the characteristics of successful higher education retention programs. More concretely, the report focuses on programs designed to cultivate

student and faculty collaboration and partnership in research and community projects, the role they played in fostering student engagement and the perceptions of coordinators regarding the programs as a contributing factor in student retention. The study was sponsored by Colciencias, a government agency that provides financial support for research projects.

STUDENT ENGAGEMENT AND PERSISTENCE

The word engagement has a plethora of definitions. However, the literature in the field of student retention shows three distinctive interpretations of the term. The first one, which is known as behavioral engagement, centers on student participation in both academic and social activities. The second one, emotional engagement, embraces attitudes, values and feelings towards academics, the school, teachers and classmates. The third one, cognitive engagement, "draws on the idea of investment; it incorporates thoughtfulness and willingness to exert the effort necessary to comprehend complex ideas and master difficult skills" (Fredricks, Blumenfeld & Paris, 2004, p. 60). According to Zyngier (2008) these definitions pose a problem as they emphasize displays of behavior of what students do and what the school does for them, which may lead to having passively compliant and ritualistically engaged students. The author states that a critically transformative perspective is necessary to truly engage students. This implies attending to their cultural world and responding critically to their lived experiences, fostering ownership and empowerment to strengthen the belief that they can impact their own lives.

Early work on student engagement (Astin 1993; Pascarella & Terenzini, 2005) showed that purposeful educational activities increase the possibilities of students to learn, and in general to achieve cognitive development. The relevance of those activities in retention is highlighted by Crosling, Thomas and Heagney (2008) who claim that a striking factor in students' decisions to abandon their careers is the significance of the learning experience. In the same vein of thought, Kuh, Kinzie, Schuh and Whitt (2005) highlight the importance of formulating meaningful educational practices to boost students' motivation so that they invest time and energy in their academic tasks. They also point out the need to allocate the necessary resources to organize learning experiences and invite students to take an active part in them.

Chickering and Gamson (1999) pointed out that those practices should be built around the following seven principles: Contact between students and faculty, cooperation among students, active learning and time on task, immediate feedback, high expectations and acknowledgment of diverse ways of learning. Vaughan (2010) shares the same view and states that effective institutional practices should be centered on "active and collaborative learning, student interactions with faculty, level of academic challenge, enriching educational experiences and supportive campus environment" (p.60). Hence, a supportive institutional atmosphere is crucial to open opportunities for students to be part of the academic community. It is by strengthening integration with the institution that students are more likely to persist on their academic endeavors. Tinto's interactionalist theory emphasized this idea and proposed that student persistence "hinges on the construction of educational communities in college, classroom, and classroom levels which integrate students into the ongoing social and intellectual life of the institution (Tinto, 1987, p. 188).

There are various enriching educational experiences available to engage students. One of them is to involve them with faculty members in research and innovation projects. Learning communities help to achieve this purpose. They have been created to foster the design and organization of curricula that bring together teachers and students' intellectual and social growth. Besides, they offer unique experiences that enrich team work and drive student participation in research and the construction of new knowledge. Barefoot (2004) points out that these communities have an impact on student involvement and interaction; particularly in commuter institutions. Janusik and Wolvin's research (2007) indicates that learning communities "can provide students with a sense of identity and with connections to faculty" (p. 169). Besides, they provide a strong sense of self-direction and motivation and increase the opportunities to develop attitudes and qualities for team work.

Experiential learning is another alternative to promote student engagement. Kolb (1984) defined it as "the process whereby knowledge is created through the transformation of experience" (p. 41). It incorporates concrete experiences, fosters reflection and abstract conceptualization, promotes experimentation and stimulates the connections between concepts and classroom discourse and the prior experiences and knowledge of the learners. Chaves (2006) states that "educators must include experiential learning in curricular designs and coursework and create opportunities for dialectical learning experiences whereby students and teachers can challenge or affirm old knowledge and at the same time create new understandings" (p. 150).

According to Fall (2006), experiential learning is closely connected to community-oriented projects at the tertiary level. These types of projects include civic-engagement and service-learning oriented activities that

become a route to connect the institution, its students and the faculty with the members of a community. They also serve as a foundation for the development of civic skills, appointed citizenship and commonwealth (O'Meara & Kilmer, 1999 as cited by Fall, 2006). The author also claims that there has been an abundance of literature that accentuates the role of civic engagement in responding to the needs of the society. In that sense, service learning is "an approach to experiential learning, an expression of values-service to others, which determines the purpose, nature, and process of social and educational exchange between learners (students) and the people they serve, and between experiential education programs and the community with which they work" (Belbas, Gorak & Shumer, 1993 as cited by Fall, 2006).

Pineda (2010) and Pineda and Pedraza (2009) demonstrated that students who participate in retention programs that foster interaction with the community improve their social skills and generate a strong sense of personal and professional commitment. The experiences of those students, who showed vulnerability and who were considered 'at risk', revealed that they developed competences that helped them to communicate more effectively with others both inside and outside the university. Moreover, their active participation in community projects of their interest generated awareness of social issues and empathy with the members of those communities. Students indicated that they had an opportunity to develop and apply their professional skills and that being part of those programs created a sense of identity with the institution that led to strengthening their academic persistence.

To sum up, an important aspect to consider when discussing engagement and persistence is that they are completely dependent upon the actions the institution proposes to empower students to achieve their full potential (Zyngier, 2008). In that regard, teachers play a very important role as the formal or informal interaction they hold with students significantly affects students' level of confidence and trust in their abilities (Vogt, 2008). Therefore, as Fabela-Cárdenas (2009) claims, it is teachers' responsibility to search for ways to foster communication, involve students in active learning and give them a 'voice' to express themselves about the processes in which they are involved.

METHODOLOGY

This study analyzed higher education programs in Colombia that optimized student retention. The main objective was to identify convergent and divergent points between the programs that showed efficient results in decreasing student attrition rates. One of the specific objectives was to document the manner in which problems associated to social and academic integration were confronted. This goal embraced the idea of examining aspects that pertained to students' social and academic engagement and their influence on their trajectories. The study was framed in a mixed descriptive and interpretative perspective and was conducted from January to September 2010 in Colombia, South America.

The project consisted of two phases. The first one focused on the collection of quantitative data by means of a questionnaire that measured variables associated to student retention. The second one utilized qualitative data; more specifically information gathered by means of in-depth interviews conducted with the coordinators of the retention programs selected. The information collected in the second phase allowed to have an ample vision of the role some programs played in engaging students from the point of view of those in charge of leading them.

Sample

A data base was elaborated considering the information provided by the Colombian Higher Education National Information System (SNIES) that indicated that there are 309 tertiary institutions in the country. Due to the fact that the system was not updated, the web pages of the institutions were explored to locate information such as the name of the president, e-mail address and the names of the individuals in charge of the retention programs. Additionally, 13 more institutions, which did not appear in the data base, were included. The questionnaire was sent to all 322 institutions. Out of these, 121 entered the online system where the questionnaire could be located and 72 responded it, which corresponds to 22.33% of the total population. Forty nine (68.1%) of the ones that answered the questionnaire were private and 23 (31.9%) were public.

Table 1: Type of institutions that responded the questionnaire

Type of institution	n	Percentage
Private	49	68.1
Public	23	31.9
Total	72	100

Specific criteria were used in order to select the institutions for the second phase of the project. Those that evidenced a decrease in their attrition rates or that did not show an increase in their dropout rates for six consecutive years were included. This criterion was examined by means of an item included in the questionnaire that requested data on dropout rates from the years 2003 to 2008 as reported in the SPADIES system. This is a software application used by the Colombian Ministry of Education to gather information about higher education student dropout, predict students' degree of vulnerability and trace their academic trajectories. Unfortunately, very few institutions reported their student dropout rates. This may be due to the fact that they were in the process of systematizing the information that the Ministry of Education was requesting at the time. A second plausible explanation for the reluctance to share this data was the feeling of apprehension at the idea of generating a negative institutional image as high dropout rates are considered a sign of school ineffectiveness.

A total of 19 institutions that met the criteria were identified. Also, 7 more were included in the interviews and were selected by means of the snow-ball sampling technique (Merriam, 2009). Members of the research team asked retention programs coordinators to recommend others who they may know and who were working on programs that fostered social and academic engagement. The names suggested were also confronted with information that appeared in the web page of the National Ministry of Education that highlighted the efforts of institutions that were working on initiatives to stop students from abandoning the higher education system.

Data collection instruments and procedures

A questionnaire was designed to gather information about the specific action plans of higher education institutions to confront student attrition. The first part of the questionnaire dealt with demographic information that included student dropout rates. The second part examined aspects connected to financial support, recruitment and transition programs, student services, and curricular and pedagogical practices to foster student academic and social engagement. This last part is the focus of this paper. The items were developed considering the most relevant aspects discussed in theory and research articles about student retention. Two experts in the field examined the validity of the instrument and adjustments were made based on their observations. The questionnaire was also piloted at a private university that willingly decided to use it. The final version was administered to the higher education institutions via e-mail in a message that included a link to access the questionnaire. The application was open from March until September, 2010 and the data gathered was stored in a repository of the Universidad de La Sabana.

The second instrument was an open-ended interview that served to examine, in depth, the characteristics of effective retention programs. This instrument was also piloted in the same institution where the questionnaire had been administered. Based on the piloting, adjustments were made and the research team proceeded to conduct group interviews with coordinators of retention programs who willingly consented to participate in this research. Each interview lasted from 90 to 120 minutes, was audio and video-taped, and later transcribed using orthographic transcription.

DATA ANALYSIS

Frequencies of responses to the items in the questionnaire were calculated to obtain a general panorama of the types of programs students were mostly involved. Percentages of responses were also calculated to identify the degree of contribution of those initiatives to student retention. For the qualitative phase, the researchers used the guidelines of the grounded approach framework (Corbin & Strauss, 2008) to analyze the data from the interviews. Open coding was done line by line in each of the interview transcriptions and recurrent themes were identified and grouped into categories. Relationships between the categories that emerged from the data were established and explanations for those relationships were then built. The members of the research team discussed the visual displays that were created to examine the relationships between the categories until reaching a consensus on their possible interpretations. These discussions served as a means to examine possible biases in the analysis, contradictions, or any other issues that could affect the interpretation of the data.

RESULTS

Because the theoretical framework behind the project indicated that engagement was fostered when students were involved in learning communities and teachers' research and innovation projects, the questionnaire requested information about the existence of these practices (different from thesis or other graduation requirements). Table 2 shows the number of institutions that responded this part of the questionnaire. The responses indicate that 95,1% (n= 39) had students participating in learning communities, 72,5% (n= 29)

included projects that connected students to teachers' research projects, and 61,5% (n=24) had innovation programs in which the students were involved.

Table 2: Institutions that reported students' involvement in different types of projects

Type of Program	n	%	Total that responded the item (n)	Total %
Involve students in learning communities	39	95,1	41	100
Involve students in research projects	29	72,5	40	100
Involve students in innovation projects	24	61,5	39	100

The higher education institutions that answered the questionnaire were also asked to rate the degree of contribution of each of the three forms of engagement in a 1 to 4 scale than ranged from high contribution to no contribution to student retention. The following table shows that 53,8% and 52,4% of the institutions that responded this part of the questionnaire considered that learning communities and research led by teachers, respectively, contributed in a medium degree to student retention. In a less proportion, 40% of the institutions indicated that innovation projects oriented by teachers had a medium contribution to retention.

Table 3: Perceived degree of contribution of student involvement in 3 types of practices to student retention

Degree	Learning communities led by teachers	Research projects led by teachers	Innovation projects led by teachers
High	23,1%	42,8%	40,0%
Medium	53,8%	52,4%	40,0%
Low	23,1%	4,8%	18,7%
None	0%	0%	1,3%

Involving students in academic work that transcends the classroom

Harper and Quaye (2009) point out that a key aspect in student persistence is the capacity of institutions to generate interaction and integration in meaningful practices that transcend the classroom. This is certainly an aspect that emerged in the interviews conducted in this study. The higher education institutions that did not have an increase in dropout rates stimulated the involvement of students with their social and academic milieu through participation in what has been known as research '*semilleros*'. The term builds on the notion of 'seedbeds' and is used metaphorically to refer to study groups that are the starting point for future development. The objective of those '*semilleros*' is to refine young researchers' skills and provide them with professional development opportunities so that they shape their abilities and become permanent members of the research groups led by teachers. The institutions allocate financial resources to teachers interested in creating these study groups and invite students who have began their fourth semester in their career to be part of the groups. Call for participation is also done by the teachers themselves in their classes.

A characteristic of those study groups is that teachers develop research proposals that foster liaisons between the university and businesses, industries and organizations located in the region. Teachers conduct research that responds to their needs and interests and promote the participation of students as research assistants. An example of such partnerships can be found in the tourism industry. Colombia has been working on creating favorable conditions for people from different parts of the world to visit the country and explore the territory and the touristic attractions that the nation offers. Various universities have been working on identifying 'corridors', a label used to name the zones in the municipalities and provinces where tourism can be fostered. Once those areas are identified, teachers and their students, along with members from the tourism organizations, work together in the implementation of diverse projects that also embrace studying the negative impact of the development of tourism. More concretely, the projects focus on children prostitution, a problem that has been affecting the country recently. The following excerpt from an interview refers to involving students in initiatives aimed at working in education to prevent children prostitution:

> *When we think about organizing innovation and research projects, we begin by thinking about how we will impact the region. We think about who will be benefited by the project and how we can contribute to what they do. Then we identify the 'corridors'. We go to the municipalities, identify their characteristics and with that information we try to respond to the needs and the interest of the people in that context. There is the intention to promote projects that respond to the situation of our region. I refer to tourism and to problems associated to the development of tourism. An impact such*

as the prostitution of children. We are interested in working with education institutions to develop prevention processes, and in this project we involve our students. (Translation done by the author of this paper, interview institution 15, p. 12-13).

Implicitly, the projects aim at fostering social responsibility. It is evident that in many of the institutions interviewed, the projects in which students participated intend to promote awareness of social reality and invite them to take action. A participant mentioned, for example, the partnership created between students in early childhood education programs and 'community mothers' (women that take care of children at their homes on a daily basis and who receive a stipend from the government for this work). Teachers guide students in the implementation of pedagogical alternatives to enrich the work that is done with children and their caregivers. The development of the projects implies becoming aware of social and cultural issues that may affect the implementation of the pedagogical practices proposed:

> *In early childhood education programs we seek to integrate the work of students and community mothers. The goal is that the university impacts the social sector. A series of synergies result from this. Students in their undergraduate programs are not in a bubble. They become immersed in their realities, to which they are expected to respond. (Translation done by the author of this paper, interview institution 1, p.14).*

Fostering networks

An aspect that apparently impacts student engagement is the close association that some teachers have with members of the industry and the business sectors. Many universities hire teachers who used to work or were working in enterprises, laboratories, factories, non-governmental and governmental organizations, just to mention a few. This results in possibilities to generate networks that facilitate the insertion of students in their selected professional fields. In one institution, for example, there are 'technical visits' that are proposed to have contact with key agents in those contexts so that the students relate to their future professional environment. Students obtain first-hand knowledge of the processes implemented in the places they visit and with this information they make decisions about the projects in which they would like to participate.

In another university, students work under the supervision of managers and teachers who, in a partnership, design and implement projects according to the development plans traced for the region. One of such plan is known as 'peace and competitiveness' which aims at working with communities in remote areas or regions that were once affected by violence and poverty. The programs request that students live in those areas for a period of time, which results in a deeper knowledge of the realities of the country, as expressed in the next sample:

> *It is a very enriching experience. It's very valuable and it is an adaptation space because many students face a hard time when living in a municipality for six months. Besides, it's an interesting interdisciplinary work. You have the future designer, the mechanical engineer and the therapist together. They talk about everything, they live. They coexist. It's an experience in which get to know their country (Interview, institution 7, p. 9).*

Contextualized curricula

A recurrent issue that emerged from the interviews was the need to permanently revise and update the curriculum so that it responds to the context in which the students are expected to work as professionals. The contents of courses must be coherent and pertinent to the prospective working environment of students. They should allow students to carefully examine issues such as history, identity, socio-cultural and political aspects of the regions and their people. By reflecting upon these issues students strengthen their ties with the communities they intend to be involved with:

> *We insist on the idea that the curriculum responds to a concrete region. That region has a name, its own needs, geography, history, identity and its own socio-economic and political conditions. We expect teachers to be aware of that and maintain a pertinent curriculum (Translation done by the author of this paper, interview institution 5, p 20).*

CONCLUSIONS AND DISCUSSION

This study showed that some higher education institutions in Colombia are engaging students in research and innovation practices that foster partnership with teachers, organizations and members of the community

where students are expected to work. From an institutional point of view, such practices apparently affect students' academic persistence and they have a medium to high degree of contribution to student retention. The analysis of the interviews allowed distinguishing two clear means by which universities are engaging their students. One of them is by stimulating participation in research study groups called '*semilleros*' in which students develop and refine research skills with the permanent orientation of teachers. The second route is by cultivating collaboration between teachers and students in projects that transcend the boundaries of the classrooms and that are targeted at responding to the specific needs of the communities where the institutions are located.

Both routes to engage students have positive consequences. First of all, the partnership with teachers can foster students' commitment to their personal and professional development. If students feel they are valued and accepted by their teachers, they will work more eagerly and effectively on the tasks proposed. It is important to note that the contribution of this relationship is twofold. As Elgren and Hensel (2006) point out, student and faculty collaboration benefits from the "natural synergistic relationship between two primary objectives: ensuring good student learning outcomes and advancing the research agenda of the faculty mentor" (p.5).

Second, the involvement of students in business, industry and community projects leads to open opportunities for them to acquire knowledge about the processes and experiences that take place in real life scenarios. Besides, such participation fosters a sense of ownership and social responsibility. In relation to the first point, the contact with different agents and their expertise provides valuable insights to nurture their professional development. Regarding the second aspect, when projects are crafted to stimulate the analysis of reality and to actively participate in the formulation of solutions to specific problems, needs or interest, students feel that the work done acknowledges them. This aspect is consistent with the ideas proposed by Zyngier (2008) who state that engagement involves owning, a term that refers to students seeing themselves represented in the work. The findings also parallel those of Fall (2006) who indicates that engagement in meaningful practices embraces participation in community-oriented projects in which students consider they are making a difference. The same idea is emphasized by Zyngier (2008) who states that engagement requires "empowering-students with a belief that what they do will make a difference in their lives and the opportunity to voice and discover their own and authoritative life" (p.1773).

The results highlight the importance of reflecting upon the pedagogical models used in higher education institutions. First, it is indispensable to design multiples possibilities that allow students to become involved in hands-on experiences, and innovation and research projects oriented by teachers. Second, the myriad of pedagogical practices in and outside the classroom should promote students' intellectual and creative growth. Becoming involved in projects that address the needs or interest of the communities where the institutions are located is an optimal choice to reach that goal. Third, it is relevant to consider that creating and maintaining partnerships between teachers and students is a daunting enterprise that requires institutional commitment and support. This implies developing policies to allocate financial resources and time frames for teachers to shape their plans and adjust them to their pedagogical needs.

Teachers are at the heart of student engagement. Therefore, it is imperative to count on professionals capable of establishing networks in which students contact and communicate with members of the industry or business sectors and members of the community in general. It is teachers who exert their capacity to orchestrate the complex tasks that are required in learning communities, innovation and research projects, and the relationships that are weaved with different people involved in those projects. So, it is imperative to implement professional development programs for educators to optimize their abilities and assume the challenges of collaborative work. Underpinning this issue is the need to examine if higher education institutions are providing opportunities for teachers to refine their pedagogical competence and the extent to which students are directly affected by such competence.

204 - Teachers' Assessment at the University of Alicante: Prospects and Actions

V. Carrasco-Embuena[1]; I. Lozano-Cabeza[2], and M. J. Hernández-Amorós[3]

Department of General Didactics and Specific Didactic Areas
University of Alicante, Spain
[1]vicente.carrasco@ua.es, [2] ines.lozano@ua.es, [3]josefa.hernandez@ua.es

Abstract: Universities in Spain have the responsibility to guarantee the training and competence of their teaching staff. On the other hand, educational administrations ensure –through assessment agencies– the compliance with quality standards among those who wish to become teachers, by means of processes developed prior to their selection.

Seeking to favour teaching assessment, the Agencia Nacional de Evaluación de la Calidad y Acreditación [National Agency for Quality Assessment and Accreditation, ANECA for its Spanish initials] has developed the Programa de Apoyo a la Evaluación de la Actividad Docente del Profesorado Universitario [Programme of Support to the Assessment of the Teaching Activity performed by University Teachers] known as DOCENTIA, which has as its aim to make it easier for universities to design mechanisms to manage the quality of the teaching activity carried out by their teachers and favour their professional development as well as its recognition. The DOCENTIA Programme follows the recommendations for quality assurance made by the European Association for Quality Assurance in Higher Education (ENQA). Furthermore, its design includes the standards established by some international organisations, such as the Joint Committee of Standards for Educational Evaluation.

One of the values which pervade overall behaviour at the University of Alicante (UA) is its commitment to the promotion and assessment of quality oriented to improvement. In this paper, we deal with the objectives of the DOCENTIA programme, established at the UA on an experimental basis, its dimensions and elements, the process through which the evaluation must be performed and the analysis of the documents generated by its implementation and, finally, the results derived from its application.

Keywords: quality assurance, teaching and learning assessment, Higher Education

INTRODUCTION

Despite the difficulties and the newly-emerged challenges, Spanish universities are making progress in the process of convergence towards the construction of the European Higher Education Area (EHEA). One of the main goals during that journey is to achieve teaching and learning excellence at university education through a high-quality teaching and research action.

In the document entitled *Realising the European Higher Education Area* (2003), better known as the Berlin Communiqué, it was stated that Higher Education quality was the heart of the European Higher Education Area. For that reason, the document laid special emphasis on the support to quality at the different national and European institutional levels, and an explicit mention was made of the need to share criteria and methodologies oriented to quality assurance. On the other hand, and in keeping with the principle of institutional autonomy, the main responsibility for quality assurance at university education falls upon each one of the institutions.

As years go by, while the Bologna process keeps moving forward, the criteria, guidelines and methodologies which the European Quality Agencies (ENQA) –and the National Agency For Quality Assessment and Accreditation (ANECA) in Spain– have been designing and implementing permit to shape and make available to universities a number of transparent, comparable procedures with which they can check if the degrees, the teachers, the services, etc. reach the quality standards required.

Within this context, the University of Alicante (UA) has convincingly recognised the need to supervise the teaching activity performed by its teaching staff in order to guarantee quality regarding both teaching and student learning. More specifically, its statutes explicitly say that "*The University will look after the quality of the teaching imparted together with its adaptation to the society's needs and will ensure evolution in the teaching activity carried out by its teaching staff*" (Art. 103). In turn, its Strategic Plan (2007) assumes that one of the main values in its operation is to guarantee teaching quality, assuring comprehensive training and the accreditation of studies by means of a high-quality educational offer which can guarantee that students will acquire the academic and professional competences needed to develop their skills and favour their incorporation to the professional world.

Therefore, within the framework of the guidelines established by the aforementioned agencies, the University of Alicante sets itself as an outstanding goal to achieve on-going improvement and promote quality in its formative offer, evaluating all its areas (teaching, research and management) as well as its global operation. This is the context where we must situate the proposal for the assessment of the teaching activity performed by its teachers as part of the improvement process which guides the institution's general behaviour.

TEACHERS' ASSESSMENT AT THE UNIVERSITY OF ALICANTE: THE DOCENTIA PROGRAMME

Teaching assessment at the University is carried out by means of the DOCENTIA-UA Programme (2007). This programme forms part of a consistent evaluation system which is aligned with the policies that affect teachers, especially in the processes for their selection, with their training, with the development of their professional careers, with their promotion and, also, with their salary. Its main objectives are:

g) To effectively achieve teaching and learning quality through monitoring and improvement actions linked to the assessment results.
h) To support the training and teaching professional development of teachers.
i) To make available information for their promotion.
j) To provide data for the distribution of economic incentives for the teaching staff as well as for departments, in accordance with the *Plan de Ordenación Integral (POI)* [Overall Organisation Plan] of this University.
k) To encourage and reward teachers for their teaching effort through the recognition of best practices.

Seeking to achieve this aim, the University has established the dimensions and elements that form the Programme, which derive from the orientations suggested by ANECA (2007) and included in the *Manual de Evaluación de la actividad docente del Profesorado de la Universidad de Alicante* [Manual for the Assessment of the Teaching Activity of Teachers at the University of Alicante (DOCENTIA-UA, 2007), summing up:

Table 1: Dimensions and elements in the teaching assessment procedure (adapted from ANECA, 2007 and DOCENTIA-UA, 2007)

DIMENSIONS	ELEMENTS	
I. TEACHING PLANNING	1. Teaching organisation and coordination	Organisation modalities
		Coordination with other teaching actions
	2. Teaching and learning planning	Foreseen learning results
		Foreseen learning activities
		Assessment criteria and methods
		Materials and resources for teaching
II. TEACHING DEVELOPMENT	3. Teaching development and learning assessment	Teaching and learning activities performed
		Assessment procedures
III. RESULTS	4. Results in terms of formative objectives	
	5. Teaching activity review and improvement: training and innovation	

The dimensions are assessed using the gradation scale suggested by ANECA, which distinguishes four categories or grades (1-4). They respond to the following parameters: **adaptation** (referred to teaching activity; to the organisation, planning and development of teaching and to the evaluation of their students' learning, as well as to the professional competences described in the syllabuses); **satisfaction** (expressed by the opinion of interest groups: mainly students); and **orientation towards improvement** (reflection on the actual teaching activity carried out by teachers).

EXPERIMENTAL APPLICATION OF THE PROGRAMME

The first experimental phase of teaching assessment started in 2007. During this transitional period, it was compulsory for full-time teachers who reached between five and ten years' experience working at the university in 2008. Nevertheless, teachers involved in promotion, accreditation or qualification processes could also participate in the process voluntarily.

Figure 1 shows the participating teachers according to the centre they belong to. We can see that the seven centres which form the University are represented, a majority corresponding to those who belong to the Faculties of Science (29.49%) and Letters (25.64%). These centres are the ones which have a higher number of teachers with tenure, which underlines their importance a priori, taking into account the conditions established for the participation in this experimental phase.

Figure 1: Participating teachers distributed by centres

On the other hand, various agents were involved in the process:
o) The participating teachers, who carry out a self-assessment of their teaching activity.
p) The academic leaders (Heads of Department and Deans), who assess the extent to which the activity performed by teachers adapts to their teaching assignment.
q) The students, who express their opinion about the teaching imparted by a specific teacher.
r) The Centre's Assessment Board, which is responsible for issuing a summary-report of the comments made by the previous agents. The Board was formed by two evaluators from the centre or faculty in question, one from another University centre and two external evaluators who did not belong to the University of Alicante. They all had to demonstrate that their teaching activity had been evaluated positively for at least two years. The Board issued a global assessment, which was expressed using the terms: very favourable, favourable and unfavourable.
s) Guarantee Board. In charge of settling the allegations presented against the evaluation reports drawn up by the different Boards. Formed by seven members appointed by the University's Governing Council in accordance with the criteria based on candidates' teaching and assessing experience.
t) Quality Technical Unit (UTC for its Spanish initials). A technical and support element for the different agents involved in the process. It is responsible for the preparation of the information and evidence available at the institutional databases of the University.
u) Education Sciences Institute (ICE for its Spanish initials). In charge of the design, application and follow-up of the training plan to be implemented by those teachers whose assessment results are not satisfactory. It additionally has the assignment of orienting teachers when filling in the self-report.
v) Deputy Vice-Chancellor's Office for Strategic Planning and Quality. Responsible for coordinating interaction between all the agents involved in the process.

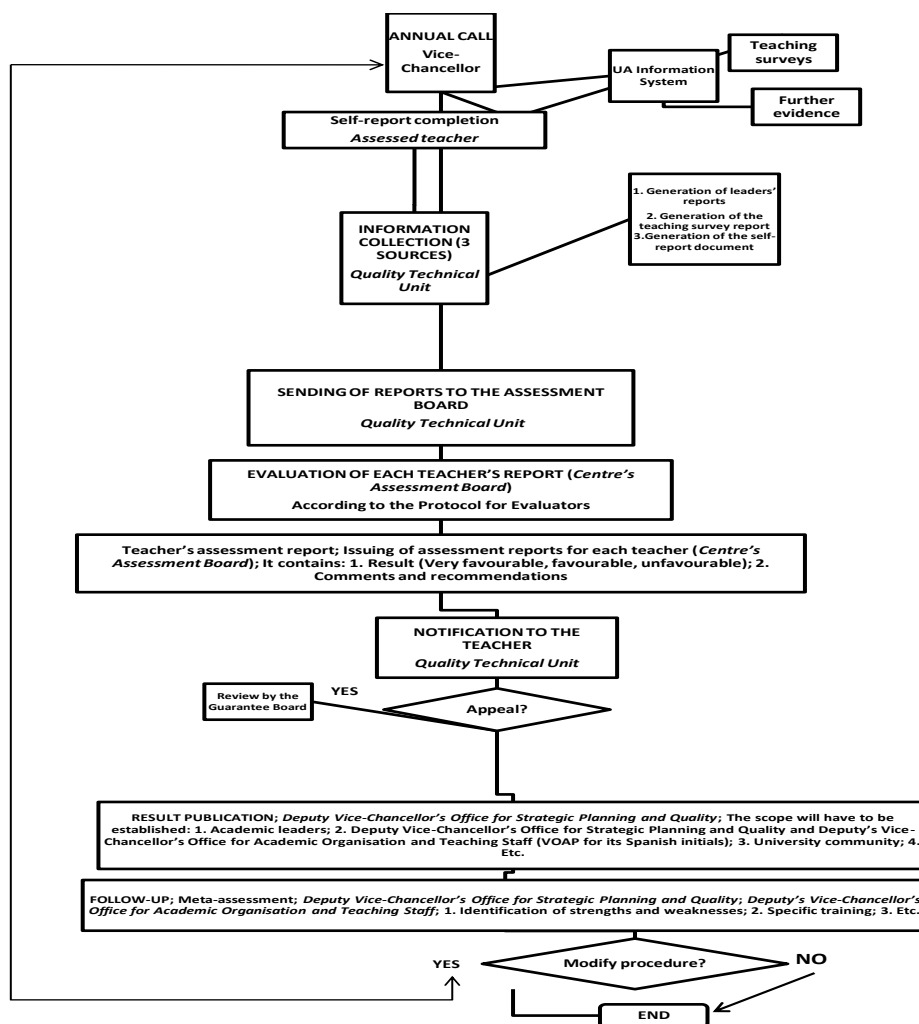
Figure 2 permits to visualise a summary of the sequence corresponding to the phase of experimental application of the DOCENTIA programme, carried out during the 2007/08 academic year.


Figure 2: Assessment process (Source: DOCENTIA-UA, 2007)

Information collection was carried out through the base documents completed by the aforementioned agents. These documents are:

1)Self-report, with three modalities: *initiation* (teachers with a maximum of five years' experience), *consolidation* (teachers with between six and twenty-five years' experience) and *senior* (teachers with over twenty-five years' experience). This document has the characteristics of a portfolio which includes the teachers' own reflections about the teaching activity performed.

With the aim of facilitating analysis and reflection, the document focuses on three dimensions: *teaching design* (teaching guides), *teaching performance* (physical/in-class teaching practice) and *learning results* (academic achievements). In turn, it is subdivided in three sections related to teaching possibilities and conditions (context), to teaching coordination and management, and to teaching guide design.

The only difference existing between the three modalities concerns the self-report in the senior modality, which includes a specific section to explain the reflection on one's own teaching career, on training and work conditions among young teachers, on the viability of the changes operated, and on the orientation proposals addressed to new teachers.

2)Academic leaders' report. It is drawn up by the heads of department and the deans or centre directors. The report is related to the planning, development and results of the teaching activities developed by teachers over a five-year period.

3)Student survey. It is a questionnaire with ten questions about the teaching imparted by the teacher (teaching guide, communication and physical as well as virtual tutorials), motivation strategies, training and knowledge of the subject, teaching materials, adaptation of the teaching guide components and general assessment). It includes a 0-to-10 assessment scale.

4)Evaluation report protocol. The responsibility of completing it falls upon the evaluators in the Centre's/Faculty's Board, with three modalities which correlate with the aforementioned

professional categories. The sources of information to estimate quality evidence are the teaching guides for subjects, the teacher's self-report, the leaders' reports and the student surveys. The assessment scale includes four gradations: "Highly appropriate," "Appropriate," "Hardly appropriate" and "Inappropriate." The protocol for the senior modality adds two more elements: student performance rates and the data from the *POI* (Overall Organisation Plan).

5)**Teaching activity evaluation report**. The Assessment Board uses this instrument to transmit the overall assessment with the following terms: "Very favourable", "Favourable" and "Unfavourable".

6)**Request to appeal before the Guarantee Board.** It makes available to the assessed teachers the procedure to revise their assessment.

EXPERIMENTAL PHASE RESULTS

Figures 3 and 4 show the results of implementation in an experimental phase of the teaching activity assessment procedure at the University of Alicante. We can see in Figure 3 that 83.33% of the reports have been favourable, 16.7% being very favourable. It must be underlined that no unfavourable reports have been obtained. Therefore, it is obvious that the results are highly satisfactory.

Figure 3: Teaching assessment overall results at the UA

In turn, Figure 4 shows the results distributed by UA centres and faculties.

Figure 4: Teaching assessment results by centres

It can be checked that only the Nursing School did not obtain very favourable results in the final report. On the other hand, the Faculty of Law is the centre which obtained the highest percentage of very favourable results (33.33 %). Although it is undeniable that the results are satisfactory, there is always margin for improvement in education quality matters. The teaching assessment carried out during this first experimental phase is just a small part of the teaching activity at the University and, therefore, we will have to wait for the results of a wider sample than the one analysed in this case. On the other hand, even if they confirmed the results obtained with the sample examined here, there would still be a wide margin for improvement.

CONCLUSIONS AND PROPOSALS

The first conclusion that can be inferred from the analysis performed is that the results obtained during the experimental phase of application of the Docentia programme at the University of Alicante are clearly satisfactory. On one side, the instruments used have turned out to be functional and efficient for the purpose they were designed to achieve. On the other side, the assessment of teaching performance demonstrates that it responds to positive standards. However, quality is an 'infinite' magnitude, even though that represents a *contradictio in terminis*. That is why satisfaction with the achievements made is never complete. In fact, the University has reviewed the procedure described, has studied the suggestions and comments made by the teachers and those involved in the assessment process and has drawn up new protocols for the application of a second experimental phase planned to be developed during this year 2011. The new instruments are included in the document entitled *Procedimiento de Evaluación de la actividad docente del Profesorado de la UA (Fase experimental 2010)* [Procedure for the Assessment of the Teaching Activity performed by UA teachers (Experimental Phase 2010)].

The EHEA construction process is inducing modifications which affect the core of European university structures. Methodological strategies are being transformed with a defined orientation towards the improvement of university teaching quality. Furthermore, the progressive implementation of internal and external quality assessment procedures is having a strong impact on the improvement of teaching activity.

Therefore, a second conclusion that can be drawn from the data provided by this paper suggests that the universities and interest groups know how important it is to improve education quality and also how necessary it is to strengthen collaboration between institutions and quality agencies. It consequently seems to us that it is highly advisable to complete this experimental introduction phase of the DOCENTIA Programme to ensure the implementation of the teaching assessment system at the University of Alicante as a whole. Obviously, it cannot be an isolated action but just one part of the general improvement plan for university services contained in its Strategic Plan. That requires human, material and informative resources. The University has a Quality Technical Unit with a valuable human team that must provide their effort to obtain reliable information about the value of indicators, so that they can be used efficiently in the management of improvement processes focused on training and also on the services delivered by this institution.

205 - Internal Quality Assurance at the University of Alicante: Process and Prospective

V. Carrasco-Embuena[1]; A. Giner-Gomis[2]; M. Iglesias-Martínez[3]

Department of General Didactics and Specific Didactic Areas
University of Alicante, Spain
[1]vicente.carrasco@ua.es, [2]a.giner@ua.es, [3]marcos.iglesias@ua.es

Abstract: This presentation has a twofold objective. On the one hand, it summarises how quality culture has entered the Spanish university system; and on the other hand, it analyses how this process is being implemented in the University of Alicante context.

The conceptual framework which serves to contextualise this interpretative analysis of the situation regarding quality assurance systems at university education stems from the mainstream literature on EHEA construction.

Document analysis was the methodology chosen for this study and we have also examined the official documentation as well as the regulation which has governed and developed this process during the last ten years, a period which concludes with full activity on the part of the external assessment agencies created, which act as guarantors of the quality process that has been incorporated into the Spanish university system. The design and implementation of programmes for the qualitative improvement of the teaching staff, of the different qualifications and centres, can be easily illustrated looking at the University of Alicante, where the authors of this paper have checked the degree of assumption and implementation of the different quality improvement programmes that this academic institution is developing.

Keywords: quality assurance, assessment, accreditation, EHEA

THE SPANISH UNIVERSITY OF THE TWENTY-FIRST CENTURY

Globalisation has caused a deep impact on the spheres that shape the different societies worldwide. Higher Education has not been left out of this phenomenon (Castells, 2009; Giddens, 2007; Hargreaves, 2003; Mattelart, 2001; UNESCO, 2005). The context of global economy forces universities to adopt a proactive attitude towards their environment and, therefore, the most industrialised countries have developed processes to integrate the international dimension into teaching, research and educational services. However, the dissemination of these processes makes it necessary for these academic institutions to establish quality assessment and assurance mechanisms in their activities and programmes, as this will allow them to compete successfully in an increasingly universal context.

The term 'quality' has traditionally been associated with the concepts of excellence or outstanding performance. Much has been written about the meaning of quality at Higher Education during the last few decades, and multiple definitions have emerged (Harvey & Green, 1993; Parri, 2006). Perhaps one of the most widely accepted defines it as "suitability for its purposes." This definition means that the institutional purposes materialise in the principles and aims proposed, which show their quality precisely when they are achieved.

As a methodological and expositive option, we will deal with this process contextualising it in the Spanish territory from a socio-historical perspective which, as an inclusive framework, embraces and gives meaning to the qualitative transformation process that the university is gradually undertaking.

University education in Spain was clearly elitist until the second half of last century. Different circumstances gradually modified that reality, especially the widespread access to Higher Education, the increased social interest in the performance of universities in the research field and also the growth of financial resources and the progressive consolidation of university autonomy.

In the 1980s, many university systems around the world started to be regulated with new legal frameworks which stressed the independence of universities. In that context, the *Ley de Reforma Universitaria* [University Reform Act] of 1983 represents a turning point in the status of universities, as it establishes a new model for the relationship between University and State based on the autonomy of the former. Later on, from the second half of the 1980s, the Spanish university joins the EHEA construction process and begins to

design its own convergence process, progressively outlining a renewed European Higher Education system (Colás & De Pablos, 2005; Goñi, 2005; Benito & Cruz, 2005; García, 2006; Martínez & Sauleda, 2006).

The Bricall report (the Spanish equivalent to what the Delors, Dearing or Attali reports meant in other European territories) was published in 2000. This report suggested the introduction of an accreditation system for academic qualifications at the Spanish university and the subsequent creation of an accreditation agency that could perform this task with full guarantees.

The 2001 University Act (LOU for its Spanish initials) incorporated the principles of assessment and accreditation, giving new competences to Universities and Autonomous Regions. It supported society's trust in its universities and demanded from them the consequent responsibility of answering to the educational administrations and the society itself, urging them to be efficient when using the public resources that were placed at their disposal. On the other hand, new management and coordination powers were designed and foreseen for the Autonomous Regions.

One of the main reasons for the modification of this Act (Spanish initials, LOMLOU) carried out in 2007 was to boost the role and responsibility of all the agents involved in the university system. The new text pays special attention to intergovernmental relationships and also to coordination and cooperation in the academic context. The creation of the *Conferencia General de Política Universitaria* [University Policy General Conference] and the constitution of the *Consejo de Universidades* [Council of Universities] with advice, cooperation and coordination functions in the academic field are both efforts in that direction.

THE AGENCIA NACIONAL DE EVALUACIÓN DE LA CALIDAD Y ACREDITACIÓN (ANECA) [NATIONAL AGENCY FOR QUALITY ASSESSMENT AND ACCREDITATION]

The concern for quality increases the external activities of Higher Education institutions. It also influences the creation of agencies with functions that include making sure that universities assume responsibility for the resources allocated to them, providing an independent testimony of the quality level achieved in order to improve quality in the services that they deliver.

One of the main innovations in the aforementioned LOU is the introduction of external quality assessment mechanisms with transparent criteria and procedures in the Spanish university system. That was the reason for the creation of the National Agency for Quality Assessment and Accreditation (ANECA for its Spanish initials) which develops its assessing activity in an independent way to measure the Public Higher Education System's performance, as a means to reinforce its quality, its transparency and its competitiveness. The modification of LOU made in 2007 has a lot to do with the boost given to ANECA activities, favouring its active participation in the verification of qualifications, in the assessment of the academic merits accumulated by the future teachers with tenure, in the assessment of teachings and institutions, and in the assessment of the teaching staff during the phase prior to their hiring. The modification also establishes it as a significant source of information. Its action plans foresee the preparation of studies and reports derived from its assessment activities and from the analysis of university quality indicators. This information is oriented to satisfy the needs of the different interest groups (Ministry of Education, Universities' Social Councils, Students' Associations, etc.).

These are the programmes with which ANECA contributes to the implementation of the assessment function in the different contexts:

AUDIT Programme. Addressed to university centres with the aim of guaranteeing the establishment of an internal quality assurance system in those centres. It combines different elements such as formative offer, teaching development, academic staff, training results, etc.

DOCENTIA Programme. It assesses the teaching quality provided by teachers.

VERIFICA Programme. It evaluates the proposals for syllabuses formulated by universities, and especially their alignment with the fixed objectives.

MONITOR Programme. Designed to supervise the implementation of an already-established official qualification until the moment when it is re-assessed for the purpose of renewing and confirming its suitability (accreditation) once again.

EVALUACIÓN DE PROGRAMAS OFICIALES DE POSGRADO [ASSESSMENT OF OFFICIAL POST-GRADUATE PROGRAMMES]. An instrument to assess the proposals for post-graduate courses at the universities located in Autonomous Regions which do not have their own assessment agency.

MENCIÓN DE CALIDAD A PROGRAMAS DE DOCTORADO [QUALITY MENTION FOR DOCTORATE PROGRAMMES]. This assessment implies recognising scientific and technical as well as formative excellence in some specific doctorate programmes.

Finally, ANECA has available two types of programmes —depending on the professional categories we plan to access— to make it easier for university centres to select more competent and better trained teaching staff:

PARA LA CONTRATACIÓN DEL PROFESORADO NO FUNCIONARIO [FOR HIRING TEACHERS WITHOUT TENURE]

It assesses the teaching and research activity, as well as the applicants' academic training for the access to the 'teacher on a contract' categories established in the LOMLOU (lecturers without tenure).

NATIONAL ACCREDITATION (ACADEMIA Programme).

It evaluates the profile of the applicants who wish to join the group of university teachers with tenure (i.e. *Profesores Titulares de Universidad* [University Senior Lecturers] and *Catedráticos de Universidad* [University Professors]).

In turn, ANECA cooperates and collaborates intensely with the assessment agencies based on the Autonomous Regions[135] and works through a network with European agencies, helping to develop the European university space and strengthen the universities included in the Spanish system. In short, it has as its essential aim to contribute to quality assurance within the university system, introducing elements associated with innovation, competitiveness, comparability, transparency and accountability.

Within the framework of its working plans, it has direct and permanent contact with each one of the universities. It analyses their specific needs and signs agreements with them to materialise the support established between both parties in consulting, methodology and financing matters, so that we can face the teaching accreditation and certification processes with a success guarantee.

In turn, universities have drawn up institutional plans to promote, raise sensitivity and favour self-assessment, improvement, certification, and accreditation initiatives. With that aim in mind, most universities have created quality technical units, which have as their purpose to design and implement plans and programmes included in their strategic plans, which are in turn always oriented to the achievement of the purposes described.

LA AGENCIA VALENCIANA DE EVALUACIÓN Y PROSPECTIVA. (AVAP) [VALENCIAN ASSESSMENT AND PROSPECTIVE AGENCY]

The *Agencia Valenciana de Evaluación y Prospectiva (AVAP)* [136] [Valencian Assessment and Prospective Agency] was created in 2006 for the evaluation of university, scientific and technological activities. Apart from being an agency dedicated to the assessment of scientific and technological university programmes, it aims to be a prospective agency in those same fields, an observatory of the foreseeable changes in the areas considered strategic for economic and social development in the Valencian region.

In 2010, the *Comisión para el Seguimiento y Acreditación de los Títulos Universitarios Oficiales (SATUO)* [137] [Board for the Monitoring and Accreditation of Official University Qualifications] prepared the Protocol for the Monitoring and Renewal of the Accreditation for Official University Qualifications, which was later ratified and approved by the *Conferencia General de Política Universitaria* [University Policy General Conference] and the *Consejo de Universidades* [Council of Universities].

This document outlines the characteristics corresponding to the system of university qualifications that will receive public recognition. This catalogue includes the so-called official qualifications, the validity of which in the whole national territory requires the previous elaboration by the government of the guidelines and conditions to obtain them

On the one hand, this protocol offers guarantees for the monitoring of the official qualifications with the aim of ensuring the effective implementation of teachings in accordance with what is established in the syllabus introduced. This supervision implies analysing the report for the accredited qualification, a specification of the teaching planning carried out and the identification of problems, amongst other aspects.

Assessment agencies, together with universities, play an important role in the monitoring procedure, as they must draw up detailed reports with which they will be able to ensure the availability of the best possible information to make the decisions of renewal or rejection regarding the accreditation of the qualifications under assessment. The indicators proposed for this purpose are: i) performance rate in the qualification; ii) dropout rate; iii) efficiency rate; and iv) graduation rate.

In 2010, the AVAP specified the protocol for the monitoring of university qualifications in the Valencian Autonomous Region. These were the objectives sought with this protocol:

e. To ensure the effective implementation of the teachings already introduced, in accordance with the content of the syllabus for the verified qualification by the *Consejo de Universidades* [Council of Universities].
f. To guarantee public availability of the pertinent and relevant information
g. To detect possible deficiencies in the implementation of the qualification, suggesting recommendations and improvements.
h. To identify best practices for their dissemination within the framework of the university system.
i. To provide relevant information to analyse the extent to which the degrees adapt to the European Higher Education Area.

Simultaneously and in parallel with the regulatory development and the initiatives undertaken for quality assurance on an international, national and regional level and being aware of the importance that quality has in all its institutional contexts, the University of Alicante has been developing actions meant to achieve the quality and progress objectives in the Higher Education offer it is responsible for.

HISTORICAL APPROACH TO THE INCORPORATION OF QUALITY IN THE ALICANTE UNIVERSITY CONTEXT

Quality assessment is a complex and difficult matter. Until very recently, quality was exclusively addressed from quantitative parameters (volume of resources per student, number of students per teacher, etc.). In recent years, however, a new conception has emerged in which other qualitative data prevail over quantitative information. These qualitative data refer to the analysis of people's performance or the efficiency in academic contents, amongst other elements.

On the one hand, this quality assessment processes imply the guarantee of university services within an increasingly diversified context. On the other hand, they are approached as contributions to university teaching improvement. This means that quality assessment somehow seeks to control the university system and, at the same time, it facilitates and increases freedom for the university institution, which in turn entails accountability by means of systematic assessments of its activity which have consequences.

The two essential goals of assessment are to identify the institution's strengths and weaknesses (quality state diagnosis) and make that information available to society. The assessment of the university system permits to build a quality system which, according to Michavila (2005), must consider at least five functions:

- to generate strategies for the improvement of teaching, research and management
- to act as an accountability mechanism before governments and society
- to be an instrument that provides public information about the activities performed by the university
- to facilitate the introduction of differential financing systems
- to be used as a programme accreditation mechanism.

Within this framework, it becomes essential to draw a clear distinction between the instruments and goals of the university system. Assessment is a tool at the service of the objectives sought by education, teaching and research. It must be consequently made clear that the objective is not to assess and, therefore, we cannot organise the university system from the premise of facilitating the application of what are nothing but instruments for the achievement of its goals and not its objectives.

Universities have drawn up institutional plans to promote, raise awareness and favour self-assessment, improvement, certification and accreditation. Furthermore, most of them have created quality technical units to make easier the implementation of their strategic plans oriented to the aims described above.

The University of Alicante has been involved in the different quality assessment plans and programmes which have been implemented at Spanish universities since the 1990s. It participated in the first *Programa Experimental de Evaluación de la Calidad del Sistema Universitario* [Experimental Programme for Quality Assessment in the University System] (1992-1994) and in the *Proyecto Piloto Europeo* [European Pilot Project] (1994-1995) which encouraged the adoption of a common assessment methodology for Higher Education. Also, from 1995, in the *Primer Plan Nacional de Evaluación de la Calidad de las Universidades (PNECU)* [First National Plan for University Quality Assessment] which was in force until 2000 and later continued since 2001 with the 2nd Plan (PCU). The first phase of the *Primer Programa de Evaluación Institucional* [First Institutional Assessment Programme] started in 2003. The second phase of this programme was undertaken in 2008 with the presentation of the qualifications which have completed at least three promotions with the current syllabus.

All these plans have made it possible to gradually address the assessment of university quality in Spain and shape an assessing culture which answers to society using the mandatory reports.

In 2002, the University of Alicante created the *Unidad de Planificación Estratégica y Calidad (UPEC)* [Strategic Planning and Quality Unit] with the function of providing technical and administrative support to the quality improvement actions undertaken by the UA. This unit functionally depended on the *Vicerrectorado de Planificación y Asuntos Económicos* [Deputy Vice-Chancellor's Office for Planning and Economic Matters].

In 2004, the UPEC was converted into the *Unidad Técnica de Calidad (UTC)* [Quality Technical Unit], which depends on the *Vicerrectorado de Planificación Estratégica y Calidad* [Deputy Vice-Chancellor's Office for Strategic Planning and Quality] and has as its specific mission:

> To facilitate development for the University of Alicante's quality policies in the teaching, research and management areas and support the agents involved in all those processes which are oriented towards the continuous improvement of this institution, favouring the creation and dissemination of a quality culture among all members of the university community, along with accountability before society. [138]

This Unit is in charge of facilitating the development of quality policies implemented by the University of Alicante in the areas of teaching, research and management. It is therefore an essential element for the dissemination of culture quality among the university community members. Among the different programmes[139] that it contributes to develop stand out the following:

DOCENTIA Programme

We can summarise the content of this Programme, to which we have referred in another paper presented to this Conference, pointing out that its objective is to assess the quality of the education imparted by UA teachers. Its procedures stem from the guidelines provided by ANECA and permit to collect relevant information about the teaching activity performed by teachers using the Campus Virtual tool. In other words, the teaching staff is assessed through the triangulation of the information coming from students (teaching survey), from the academic leaders in the centre where teaching is imparted (leaders' report) and finally, from the teachers themselves (self-report). This assessment is complemented with the evidence available in the institutional databases and is developed over five-year periods.

An initial experimental phase has been developed in which a cohort of 80 teachers was assessed and, at the moment, we are working on the implementation of a second phase, where the assessment will be extended to the whole teaching staff.

AUDIT Programme

The LOU establishes that all official qualifications must go through an accreditation process developed either by ANECA or by regional agencies, both at the moment when a specific degree is proposed (verification process) and when it has already been implemented (process for its accreditation).

Following ANECA's orientations, the UA has designed a Sistema de Garantía Interna de la Calidad (SGIC) [Internal Quality Assurance System] trying to find a balance between those orientations and its own characteristics in the actions promoted to help quality improvement in its programmes and qualifications in a continuous, systematic and structured way. This SGIC has been verified by ANECA and currently finds itself in the phase of implementation at the different faculties, after which it will be certified by ANECA. This certified SGIC will make possible the verification of the future university qualifications (degree and master's degree).

The SGIC design considers the needs of students and other social interest groups regarding the training offered by the UA. Its implementation seeks to honour the commitment to satisfy the social needs and expectations, to offer the transparency required within the EHEA framework, to incorporate ongoing improvement strategies, to efficiently organise teaching initiatives and to facilitate the accreditation of the qualifications already imparted at the University centres.

Each centre prepares a SGIC that includes the following elements related to university training:
   a) Formative offer design: Definition of objectives, student admission criteria, criteria for the eventual suspension of the degree, etc.

b) Development of teaching and student-oriented actions: Welcome and support activities addressed to students, teaching-learning methodology, learning assessment, external practical activities and student mobility, complaint and claim management, student report management and formalities for academic qualification certifications, etc.

c) Academic and teaching-support staff: Access, assessment, promotion, training, recognition and support to teaching, etc.

d) Material results and services: Design, management and improvement of classrooms, laboratories, libraries, bibliographic funds, etc.

e) Training results: Measuring, analysis and utilisation of results, labour insertion, satisfaction of different interest groups, etc.

f) Public information: Dissemination of updated information about training.

This SGIC materialises in an implementation structure formed by different bodies with their respective specific roles: Dean's team, Faculty Council, Quality Board and Quality Coordinator.

In 2009, the University of Alicante obtained a favourable assessment by ANECA in the AUDIT programme for two of its Centres: the Faculty of Letters and the Social Work School (currently integrated into the Faculty of Economics and Business).

VERIFICA Programme

During the present 2010/2011 academic year, the UA has started the implementation of the new official qualifications (degrees and master's degrees), which had been previously verified by ANECA and AVAP. There are obviously no relevant data available about this process yet, but in general it seems to be developing rather smoothly.

MONITOR Programme

In 2011, ANECA has set in motion the MONITOR programme with the aim of supervising the implementation of new syllabuses, helping universities to gradually improve the aspects which may present deficiencies with a view to their future accreditation.

A pilot project will be developed during this year based on the design of a straightforward, agile and consistent procedure structured around four broad dimensions:

a. Information for society and for prospective students

Accessibility, intelligibility and usefulness of the information included in the verification report for the monitored qualification will be checked.

b. Information for students

Attention will be paid to the accessibility and intelligibility for students of aspects related to the materialisation of the syllabus during its implementation.

c. Information about operation

Information will be requested about the way in which the implementation of the syllabus is being undertaken and about its internal follow-up procedures.

d. Information about training results

The University will look after the compliance of commitments regarding the achievement of the competences corresponding to each qualification and the values for each indicator.

This Project will be applied on a significant selection of official qualifications agreed with Autonomous Regions and universities.

PEP Programme (hiring of teachers)

We do not have specific data corresponding to the University of Alicante in this respect. However, we do have available the results from the Teachers' Assessment Programme for Hiring (PEP, for its Spanish initials) for the period comprised between January 1st and December 31st 2009, which have been published by ANECA.

We can see in this report that 61% of all the applications filed obtained a positive assessment. Breaking down the results by contract modalities, 53% of the applications for the category of profesor contratado doctor [Teacher with a PhD working on a contract] obtain a positive assessment. On the other hand, the category with the highest percentage of positive assessments is that of Ayudante Doctor [Assistant Teacher with a PhD] (78%).

By knowledge areas, the Social and Legal Sciences area provides the highest number of assessment applications (28%), 59% of which obtained a positive assessment. In turn, the Health Sciences area provides 12% of the applications, with 63% obtaining a positive assessment.

CONCLUSIONS AND PROPOSALS

The document analysis carried out about the situation of external quality assessment at Spanish universities permits to state that it is structured around three main axes: assessment of official qualifications; assessment of the teaching and research staff; and quality assurance systems for university teachings (ANECA, 2009)[140]

Regarding the first axis, the design and implementation of the official Higher Education programmes in the whole Spanish university system is representing an important challenge for the agents involved in the process. For universities, because they have had to design the qualifications; and for assessment agencies, because they have played a significant instrumental role, assessing the new qualifications and guaranteeing their quality through the VERIFICA programme.

Because of the need to harmonise the new qualifications with the EHEA, the design of new syllabuses has taken into account relevant aspects related to the content of the subjects proposed, to the teaching process, to students' learning and to the context where the university carries out its teaching role.

Universities and quality agencies have maintained an intense dialogue throughout the qualification design phase which has contributed to improve the quality of the different degrees and master's degrees. This dialogue must be further encouraged during the new monitoring phase for the qualifications already implemented (MONITOR programme) which has just started, as this will improve them and make universities' accountability before society more efficient.

The second axis mentioned above refers to the assessment of the teaching and research staff. On the one hand, the assessment processes which are being carried out at the moment guarantee that the future teachers and researchers fulfil the specific requirements to develop their functions, either forming part of the university teaching bodies or through contracts signed with universities. On the other hand, they permit to recognise quality in the teaching activity, in research and in the management of teachers who are already developing their professional activity at universities.

The national accreditation system (ACADEMIA Programme) has reduced the costs of the previous national qualification system, both for teachers and for the Public Administration. It additionally places at the disposal of universities a wide range of candidates for their selection of the teachers who will eventually occupy posts in the university teaching bodies. Nevertheless, it must be highlighted that the majority of the staff accredited gets their promotion at their own University, which means that competitiveness is practically non-existent during the internal candidate selection process.

The assessment prior to the hiring of teachers and researchers is following a downward tendency, although the number of assessments performed is still very high. It is worth highlighting that, in our opinion, it is important to encourage a vision of assessment for accreditation that makes mutual recognition between agencies effective. Progress has been made in this direction during the last few years, and that is positive because the process is now more clearly defined, a lesser effort is required, and participants have a more positive perception of a process that is arduous and problematic in principle. It would be advisable to study this possibility in more depth for the future.

As for the teaching and research staff, programmes for the assurance and recognition of the correct performance by teachers who are already working at universities have also started to be applied. In many Autonomous Regions, like ours for example, either local agencies or ANECA assess the individual merits of a part of the teaching staff, this assessment being the criterion for the granting of regional salary complements. It must be highlighted that there are differences between Autonomous Regions, both regarding the assessment procedures for the granting of complements (merits assessed and ways to do it) and in relation to the amounts corresponding to the complements received by the positively assessed staff.

The third axis concerns quality assurance systems at universities. The AUDIT programme has as its aim to orient universities in the design and implementation of the aforementioned SGICs. The degree of involvement in the implementation of the Programme has been quite high (over two thirds of the universities). In most cases, the final result obtained has been positive, though with recommendations which highlight the convenience of making improvements in aspects such as the way in which interest groups take part in the design and development of some actions, the mechanisms for the implementation of the improvements derived from the revision process and the need to provide more details in relation to the extent of accountability.

The assessments carried out through this Programme have proved useful in the context of verification for new qualifications, taking into account that it is compulsory to have reliable quality assurance systems. As the process of implementation continues with more new qualifications, many of the favourably assessed

SGIC designs will have to be implemented by the universities themselves, as is happening at the University of Alicante.

Coexisting with the AUDIT programme, the DOCENTIA programme has been designed to favour quality improvement in teaching activity. Universities have integrated their procedures into the SGICs, considering the relevance of the activity concerned. This is the course of events at the University of Alicante at the moment. Practically the whole of the Spanish university fabric has taken part in the Programme and all the reports issued by the assessment agencies have been favourable. On the whole, it can be concluded that the designs suggested by universities to assess the teaching activity performed by their teachers should improve in their implementation process in order to achieve:

> a) a higher degree of teaching activity discrimination in terms of quality. We are under the impression that the procedures designed still do not permit to really distinguish the staff showing the best performance.
> b) a greater weighting of results to explain quality in teaching activity.
> c) more descriptive quality in the assessments performed, so that they can become more useful to teachers, to universities and to agencies.
> d) a better operating link between the assessment results and the consequent decisions in the areas of teacher training, promotion and recognition.

Despite being aware of the fact that it is still in its infancy, the overall analysis about the implementation of the quality assurance system at the University of Alicante allows us to be hopeful in relation to its future development. We insist on the need to integrate it into the general improvement plan for university services included in the Strategic Plan of the UA. This requires human, material and information resources. The University has a Quality Technical Unit with a valuable human team that must provide their effort to obtain reliable information about the values for the key indicators, so that they can be efficiently used to manage the processes focused on the improvement both of training and of the services delivered by this institution. At Faculties, the different managing teams and a large proportion of the teaching staff have demonstrated the sensitivity needed to implement the process successfully. Therefore, it is necessary to activate a type of institutional leadership which can boost the synergies required to guarantee quality assurance in their research activities and training programmes, boosting its international dimension and, ultimately, favouring its successful positioning within the context of global economy and the society-network.

NOTES

1. ANECA is a national foundation which certifies the qualification and accreditation of teachers to impart teaching at Spanish universities. The Autonomous Regions have created regional agencies with similar functions within their respective areas of competence; here is a list of those agencies:

Agencia Andaluza de Evaluación (AGAE). [Andalusia]
Agencia de Calidad y Prospectiva Universitaria de Aragón (ACPUA). [Aragón]
Agència de Qualitat Universitària de les Isles Balears (AQUIB). [Balearic Islands]
Agencia Canaria de Evaluación y Acreditación Universitaria (ACECAU). [Canary Islands]
Agencia de Calidad Universitaria de Castilla-La Mancha (ACUCM). [Castile-La Mancha]
Agencia para la Calidad del Sistema Universitario de Castilla-León (ACSUCYL). [Castile-León]
Agència per a la Qualitat del Sistema Universitari de Catalunya (AQU). [Catalonia]
Agència Valenciana d'Avaluació i Prospectiva (AVAP). [Valencian Region]
Axencia para a Calidade do Sistema Universitario de Galicia (ACSUG). [Galicia]
Agencia de Calidad, Acreditación y Prospectiva de las Universidades de Madrid (ACAP). [Madrid]
Agencia de la Evaluación de la Calidad y Acreditación del Sistema Universitario Vasco (UNIQUAL). [Basque Country]

2. Act 5/2006, of May 25th, for the creation of the *Agencia Valenciana de Evaluación y Prospectiva (AVAP)* [Valencian Assessment and Prospective Agency]. Official Gazette No. 154, of June 29th 2006.
3. This board is formed by representatives from the Ministry of Education, Regional (Autonomous) Governments, Quality Agencies and Universities.

240 - Design of Media: Didactic Guide to Competences Development

A. Medina[1], M.C.Domínguez[2], and C.Medina[3]

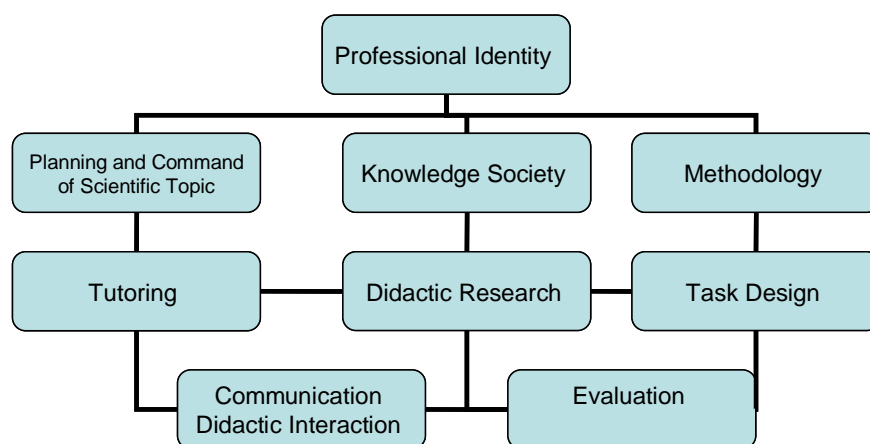
Madrid.UNED
[1]amedina@edu.uned.es, [2]codogarr9@yahoo.es, [3]tatinamedina@yahoo.es

The application of the principle "Learning throughout life" leads the implementation of new research plans in the E.E.E.S frame. This principle demands the continue follow up in learning of university professors. In order to prepare them for the latest challenges. In this context, University is the institution in charge of creating knowledge, professional development and global learning in students.

Teacher's learning must focus on those aspects more suitable for answers to Bologna requirements (1998). These requirements have been completed in the meeting of Bergen (2004) and in the one of London (2007), which summarize the most important demands in order to make come true the agreement reached.

This is our work line and we have published several researched (Medina, Dominguez, 2007, 2009, 2010, 2011) Which have contributed to present models for preparing teachers to deal with the new learning-teaching context.

In relation with previous research we want to get deeper in the learning model for teacher's competencies. (Medina, 2010: Medina, Domiguez & Gonçalves, 2011). It has become a further step in the quality and typology of the competencies of university professors.

We want to follow and boost a specific competences map, the following one:


JUSTIFICATION OF TEACHER TRAINING IN DIDACTIC COMPETENCES.

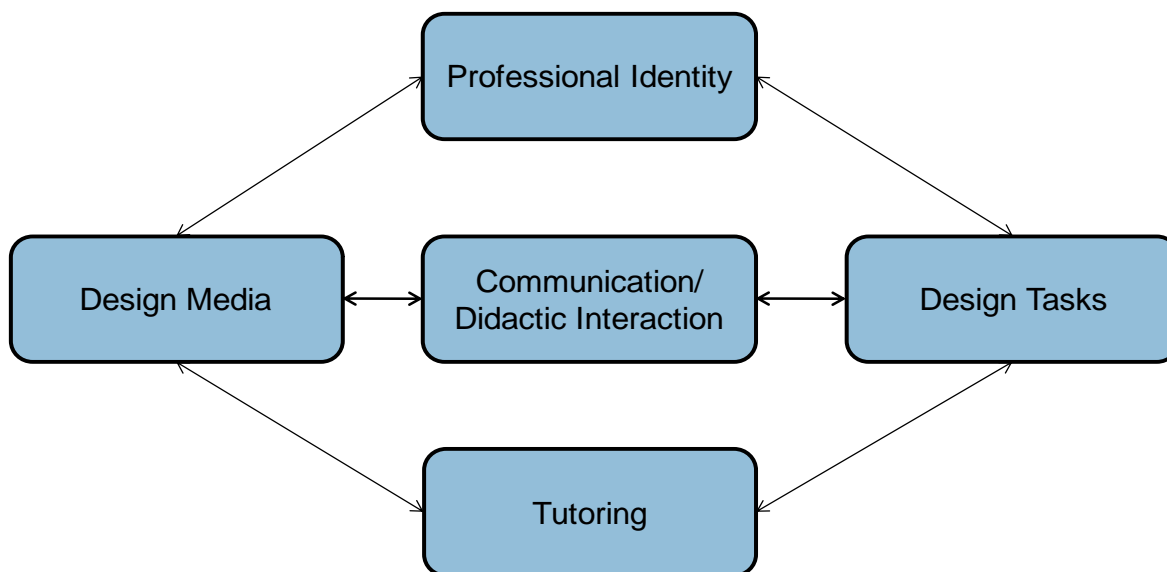
The European higher education area (EHEA) stands out as an essential end that students achieve the generic/core and professional competences that are most valuable, that allow university students become prepared and committed to new values and able to resolve efficiently and with continuous improvement the challenges of their future profession.

It we want students to acquire a high mastery of those competences, we are as a first idea and base: Have teachers acquired the necessary training to answer adequately to this necessary educational aim?

The answer has been given in previous investigations (Medina et al., 2007, 2009, 2010), (Medina, Dominguez & Conçalves, 2011), (Medina, Dominguez & Medina, 2011) and between other investigations (Medina, 2011).

It is urgent that teachers receive thorough training and high dedication in order to master the teaching competences required to face the new challenge and to act with the vigour and the relevance that the present time demands due to our integration to the EHEA.

The hypotheses that we are working on and that the study makes evident is that university teachers and specially the distance university teachers requires a deep reflection on the whole of the competences that arose from our previous research (Medina et al., 2007), (Medina, Dominguez & Gonçalvez, 2011), but in the new program initiated in December of 2010, in different university contexts and specially in the Program for Professional Development in Quito (ESPE); in the University Program for Distance Education and with the

new frame of UNED, it was highlighted that teachers must acquire the aimed and presented competences in the official curriculum, but among them the following must be highlighted because of their impact in the acquisition of the whole of the competences:


These competences make up the bases of the most representative competences of the action and quality of teaching in higher education institutions. Previous research (Medina, 2010) show that the distance education teachers require new forms of knowledge and recognition of the relevance of their task and also of the most valuable decisions to face the new challenges and the specificities of a higher education committed to enabling students and to train them to master the most relevant competences:

1. Knowledge Society.
2. New professions.
3. The universality of the job market.
4. Quickly changes.
5. Technological transformations.
6. Work flexibility.
7. An eco-training, complex and multicultural society.

Before this demands university teachers must reflect about the permanent models of change, the needs of the students and the plurality and harmony of the European titles.

Development of communication, identity, media and tutoring.
These competences make up a representative map of teacher competences that distance university teachers must master and that on the whole constitute the most relevant pedagogical practices. (Medina et al., 2011).

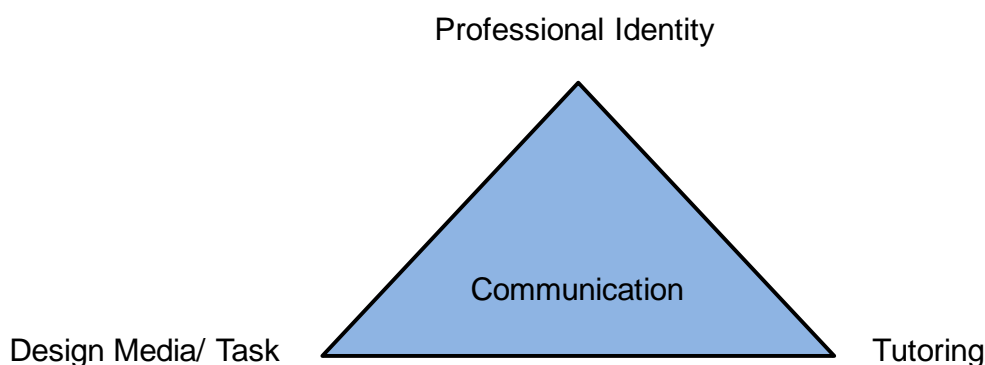
There are three reasons for this selection:
- Research of EHEA context.
- Specificities of the practice of distance university teaching. (Medina, Dominguez & Gonçalvez, 2009).
- Relevance of the program of professional development of UNED (webs of innovation and improvement plans and teacher training/ Net of Innovation and Teacher's Training (ESPE-QUITO).

Communicative Competence
The essential competence to distance university teaching is communication, basically mediated and supported by the classic and digital materials, developed through direct and virtual tutorials, which is characteristic of distance teaching methodology.

A new map is drawn and defines the new model of training that must be applied to the distance modality and that has been transformed and adapted from other modalities of normal university because the demand on the teachers is that they use platforms such as Wbcr, ALF, Moodle, etc. That implies a vigorous specialization on the part of the teachers and that the EHEA considers as evidence of the quality of the university systems that we represent.

Professional Identity

Communication

Design Media/ Task   Tutoring


This triangle synthesizes the relevance of these competences that are a priority for distance university teachers, and for any university teacher who has to consolidate them if they want their students in turn to master the core and professional competences that are demanded in order to obtain titles recognize in the EHEA.

The communicative competence in the Information and Knowledge Society is central. It's specified and makes itself evident in the use of the knowledge and professional communicative practices, attitudes and values that determine a close interaction between the components of the communicative process.

Agents – message and medium – receptor.

Expert teachers- Design of the media and tasks – Professional students.

The specificities of communicative competence in distance education makes itself evident in:

- Design media.
- Use platforms
- Combination of forums chats and e-mail.
- Development of tasks
- Tutoring USE

There is a need to deepen into the model of design of didactic media in order to achieve a empathic and comprehensive communication that facilitates the students acquisition of the competences, the advancement of academic knowledge and the anticipation and solution of the complex problems and processes of the future profession.

There is an improvement in communicative competence when we develop the professional practice centred in the design of didactic materials and the empathic performance of the tutorial conference.

This complementation between competences shows that the integration of a holistic development of the whole of the competences is required to the point that the competences configure a process and a context of mutual enrichment and reciprocity.

There is an advancement in communication through the actions and practices of improvement, among them, the use of video-conferences, forums, chats, and also the creation of study guides, didactic tools classic materials and e-books, these constitute de most adequate medium to improve the communicative processes.

The design of didactic media is in itself an authentic communicative process and we must work on the configuration of techniques and models that perfect it continuously.

Among the media of consolidated design we choose the following:

Study-guides: Thematic synthesis, as guidance and motivation to encourage autonomous learning and contributing with a schema that specifies: ccompetences, learning outcomes, contents, tasks, timing, and development of practical problems, self-evaluation and bibliographies.

Didactic units: Synthesis of the whole of the competences, learning outcomes, extensive presentation of contents, tasks, professional contexts, self-evaluation and complementary bibliography.

Design of virtual materials, in teaching platforms, organized according to an instructive and transformational sequence, with close complementation between all the resources, with higher interaction open to social networks and with the creation of new contexts of complementation between the different media

The communicative competence becomes consolidated when diverse styles, mediums and resources of presentation of culture, academic knowledge and professional issues, integrated in a new vision of the teaching tasks, are used.

MODELS OF THE MEDIA DESIGN FOR THE INNOVATION OF TEACHING

The competence in design of media for professional development builds a mode in which to base its communicative relevance and quality. In this way we improve students' motivation to use a warm style and to develop the metaphors and analogies more adapted to the field of knowledge.

The structure of the discourse must differentiate itself for its simplicity and mastery of a direct style, contributing successively with the concept, facts and theories that the students must grasp with a relevant projection to the professional environment and to the solution of future issues characteristic of the working context.

The writing of the texts is the great challenge of the teachers, who must carry out a design that is:

- Instructional-didactic.
- Literary and motivational style.
- Agreeable
- Powerful and impressive.

The text must summarize the most valuable academic advancement and inter-disciplinarity, with projection in the demands and problems of the future profession, training students in this double relevance scientific and professional, but presented in a clear and ordered way that allows the students to improve their knowledge and helps them with the challenges that are characteristic of a working environment in constant change and with an international inter-dependency.

DESIGN OF THE INVESTIGATION

Research Objectives
To identify the most valuable and relevant competences for preparing that the students acquire the teaching competences and develop a culture of improvement of the distance teaching-learning process.

Specific aims
- To disclose which are the most representative competences that the teacher must advance on in order to improve higher education.
- To select the most representative competences in order to face with vigour the demands of the EHEA.
- To value the meaning and repercussion of the communicative competences, media design, tasks and tutorials in the professionalization of university teachers.
- To determine the inter-relations between the mastery of the chosen teaching competences and the training of the students in core and professional competences.

Research problem
The research aspires to find out and value the teaching competences that are more representative and that the university teachers and specially those of distance education must master in order to meet with vigour the demands of the EHEA and to support Long Life Learning in the students, preparing them to master the general and professional competences.

People and Sample of the Research
People and Sample of this research are people are university professors from UNED in Spain (100 PHD) and ESPE of Quito (60 teachers) who value the command and importance of these competencies.

Methodology
We have used a combination of quantitative methods (questionnaire) and qualitative methods (narrative, analyze of didactic materials, interviews) methods, in order to deepen in those selected competencies.

Among this integration of methods we underline in this research the approach of ''Analysis of the Communicative Model'' used to design and test the quality of the didactic materials, selecting some dimensions of the map created by the IVED and the new characteristics of the process of design of didactic media and tutorial communication development (Medina, Dominguez, & Sánchez, 2008, 2010).

Data analysis
We present the most relevant findings that emerge from the questionnaires, discussion groups, narratives and

analysis of didactic materials performed in order to study the global relevance of the selected dimensions:
- Communication.
- Media design.
- Tutorials.
- Professional identity.

Globally, the average results of the questionnaire and standard deviation of the answers of UNED teachers, both permanent teachers (Madrid headquarters) and teachers of a variety of other centers (Canary islands, Asturias, Talavera, Vigo, etc) are the following:

Results achieved (teaching competences	Average	Standard deviation	Mode	Percentage
Communicative competence	4,4	1,04	4	66.3%
Media Design	4,1	0,7	4	83%
Tutoring	4,4	1,2	4	65,5%
Professional identity	3,9	1,2	4	57,6%

The highest value among the average correspond to Tutoring and communication, specially when you add them up

CONCLUSIONS
Distance Learning Teachers consider competencies as a suitable whole for the development of university teaching. The selection of the competencies stands out as necessary sequence of command for the right performance of professors and training students.
- Professional Identity,
- Tutoring,
- Communication,
- Media Design and Evaluation.

These competences have been chosen by university teacher as relevant to their teaching training and they are part of the challenge of modernization of the teaching profession that the EHEA demands, specially the media design and the tutoring which represent student's bases to answer to society's inter-culturality and complexity.
The close relationship and complementarity between these competences is essential in order to allow university teachers to answer to the real needs of a world in constant change and with new professions being constantly created.
The achievement of the objectives is confirmed specially when there is evidence that in order to train students in generic and professional competences, previously the teachers need to be conscious of the mastery they have achieved in those competences and they understand their competences in their prototypical dimensions:
- Learn to know and master the academic knowledge that is the foundation of the competences.
- Learn within and from the issues of their own profession, the most relevant issues that they will need to deal with, applying academic knowledge and re-creating their knowledge from the action.
- Develop the attitudes, values and codes of conduct that characterize university life and culture.

The most relevant competences to reach the full professional development of university teachers has been synthesized in the four mentioned before, with special emphasis on the design and development of classic and digital media which have been extended with a process of support, collaboration and advise from students and colleagues of different cultures.
The main conclusion is to verify that there is a close relationship close and supportive between the knowledge and the mastery of competences mentioned and the ones achieved by the students in the new intercultural, social scenario.
The relevance of this study lies in the confirmation of the updated of previous research which showed that the teachers must take an active part in the design of the university and that the guidelines for the optimal academic, human, social and institutional training of the students and future professionals happens when there is a greater coincidence between the media design and the tutoring, two essential aspects of the distance

education teacher training. Previous studies that focused on this line of research confirm this (Medina et al., 2007, 2008,2009, 2010, 2011) and (Boterf, 2008,2010).

272 - Being a University Teacher in Times of Change - The Academic Profession and its Reconfigurations

Ana Celia Bahia Silva

Institute of Education, University of Lisbon; Teacher at University of Amazonia, Brazil.
anacaliabahia@hotmail.com

Abstract: This paper is theoretically streamlined on the orientation chart in reference to Sociology of Higher Education and the analysis of the academic profession under the influence of the government policies for Higher Education. The main aim is to describe and analyze the reconfiguration of the academic profession over the on-going scenario of changes on the Higher Education context. It emphasizes the factors that influence this reconfiguration of the academic profession, that is, the redefinition of the roles and duties of university teachers. The survey takes the quail-quantitative methodological design, sequential mixed method. The theoretical views of the reviewed literature have been used both to guide the study and to favor the data double-crossing.

Keywords: Academic Profession, Mixed Methods, University Teacher Roles.

INTRODUCTION

The second half of the twentieth century witnessed intense economic, social, political, cultural, technological, educational, that impacted the higher education systems in all countries and created tensions between educational policies and international trends related to globalization, internationalization, marginalization, fragmentation, technologization, turned out to be "a complex period permeated by paradoxes" (UNESCO, 1999, p.111). The academic environment has become diverse and complex, influenced by the changes due to education policies and the relationships between university and society. The transformations of the university as a social institution and as an organization has generated changes in its structure and operation, and the dynamic of change, has generated changes caused from the external environment affects the universities and the academic work that takes place in them.

Changes in the academic profession have been highlighted in the literature, concerning the expected roles, the new roles that are now required, resulting in reconstruction of identities in response to changes in labor and roles (Taylor, 1999), a reconfiguration of the academic profession (Finkelstein, 2003, Schuster & Finkelstein, 2007), the vulnerability of the academic profession (Beck & Young, 2005). In the landscape of change that characterizes the contemporary world the academic work becomes complex, difficult and challenging at the same time, with changes and trends in the context of changing the nature of academic work.

In Brazil, we emphasize the study of Mancebo and Franco (2003) which discusses the academic work, especially the teacher-researcher who works in the graduate, and the study of Bosi (2006, 2007) that questions the precariousness of teaching in higher education and its consequences.

The university teacher is immersed in this scenario of changing demands and this is the core of our research interest: how the changes undergone by the university, higher education, affect or reconfigure the academic profession, the condition of being a university professor? The aim of the research was to understand the reconfiguration of the academic profession in the context of changes. We started with this initial question: How the changes undergone by the Higher Education affect or reconfigure the academic profession, the condition of being a university teacher?

The study was developed in two phases. First, initial exploratory, in which, after identifying the focus of interest and defining the problem and goals of the research we studied the literature to develop theoretical study and definition of the methodological design of the study. The second, a field study in two stages: a preliminary study of qualitative interviews with key informants, followed by an investigation focused on quantity, using a questionnaire to a sample of 340 teachers from three universities located in the Brazilian Amazon.

The nature of the research problem and objectives were essential elements to the methodological design and we assume a plurality to be able to capture the complex and dynamic reality of the university and the academic profession and thus, we assume that plurality with a view empirical-analytic and interpretive-qualitative methodology making use of mixed or multi method, in view of complementarily, combining

sequentially, qualitative and quantitative strategies, with the expectation that the approaches can be combined, without, however, have a simplistic view of that such harmonization is free of care and accuracy, whereas the essence of two distinct approaches, but while considering the possibility of reconciling them in a mixed methodological design, which takes the complementarily of the data, as a research strategy, with forms multiple collection and data analysis.

A BRIEF SCNERARIO OF HIGHER EDUCATION AND THE RECONFIGURATION OF ACADEMIC PROFESSION

The landscape of higher education in particular aspects related to research presents some sides of the changes hereby synthesized.

1. Decline of government commitment to the funding of universities.
The format changes require funding of public institutions to seek resources through the provision of third sector services and, at the same time, not to increase the payroll, with an overload of existing permanent staff or with the use of temporary contracts. With fewer financial resources are adopted mechanisms that force universities to seek private sources of funding and teachers faces an increase in its "usual obligations, to acquire business skills in order to convert dc its expertise in services tailored to the market" (UNESCO, 1999, p.439). In Brazil, the educational law (Law 9394/96) provides the principle of diversification of funding sources and application of this principle has had an impact in shaping the university in logic of rationalization and productivity, as Lima (1997) calls the adoption of the accounting paradigm, an increase of agreements and contracts of paid services to meet budget gaps.

2. Increased demand for higher education and growth in higher education participation.
In post-industrial society, the valuing of higher level training and recognition of its strategic importance to the social and economic development led to an increasing demand for higher education, or what Didriksson (2008) when referring to Latin America called the massification of social demand for higher education and its rapid growth. In Brazil in 1960 the 260 Higher Education Institutions (HEIs) had 93,202 students, in 1995, there were 894 HEIs with 1,759,703 students, and in 2004 relied on the 2013 HEIs 4,163,733 students, although this number corresponds to only 17.35% of youngsters from 18 to 24 years. Four years later, the Higher Education Census carried out as indicated 5,080,056 undergraduate students. This growth was achieved through the private sector expansion.

It is important to note some changes related to expanding access to higher education and a trend towards greater equity in access, with the increase and differentiation of the student population has led to a kind of transformation of elite university in mass university, which reflects the student profile in number and a more heterogeneous profile, both in background, the motivations and interests of students, the possibilities of time dedicated to studies. The so-called new public who are attending the university, demand a new way to respond pedagogically to their characteristics. Low income students more socially diverse demand that institutions of higher education have programs that address those demands, teachers prepared to deal with situations that probably they did not face before. This transition to a model of mass and the increase in the number of students with diverse interests and needs, changes in the ratio of the number of students per teacher, a workload with many classes may be reflected in the teacher's work, requiring new forms of performance, new roles and perhaps a diversity of profiles of university teachers.

Mancebo and Franco (2003) examine teachers' work in times of globalization point to changes in the basic functions of the teacher, with "new tasks" that are attached to teaching, resulting in over-work, which has been growing for teachers in especially for those which the authors call a certain "track hierarchical teacher: one that research" (p.194). These authors discuss this situation as a result of flexible work processes and products that characterizes the working world today and this logic the "teacher's work is no exception (...) new functions were added to the central pillars of its action, education and search "(p.199).

3. Diversification of roles and work intensification.
Teachers are faced with new demands and expectations reflected in the diversification of roles, expansion and intensification of activities, not only by increasing the workload of the teacher in the quantitative logic, with larger groups and with support for smaller groups or individual support, the adoption of schemes tutorials for students, new teaching methods, interdisciplinary work. But also, the expansion of its traditional functions of teaching and research, with the task of seeking external resources to facilitate research projects, preparing proposals to seek funds in a competitive environment for these resources, new responsibilities with networking with the community, industry, government and service delivery. Teachers tend to allocate more

time and attention on tasks that are best evaluated or whether they believe that the research has more impact on the rewards, apply more time in this academic function than in other academic activities.

Hargreaves (1996) calls attention to the time (how many hours teachers work) as a factor in structuring the work of teachers and notes that both are dimensions that structures the and the work is structured by the time: "far from being a trivial matter, both the amount of time available to the teachers, and to a greater extent, whoever controls this time and for what purpose are converted into crucial issues "(p.01).

There is an increased workload and fragmentation in the work of academics. The workload is not simply the number of hours of work, but mainly the elements that govern the relationships between teachers and the university as an organization, with its norms and rules. Considering the rules of academic work and how their structure, work routines, as they are sorted academic activities, evaluation criteria, it is possible to understand one important dimension of analysis, the literature has been named by the expression "working environment", or working conditions" . Stromquist et al (2007) reports a deconstruction of the academic profession, working conditions becoming worse, or status of teachers questioned and also university practices being put in doubt. Already Finkelstein (2003) uses the term reconfiguration of the academic profession, especially given that the model of full-time professor, engaged in teaching, research and service, is changing.

We understand that this idea of reconfiguration can be related to adjustments in the characteristics of academic work, re-arrangements in the form of action, in shaping the work that academics develop, escaping the typical constitution of the academic profession and probably leading to a differentiation and segmentation career with a smaller number of teachers with dedication to research and knowledge production while others working more in undergraduation, i.e. the teaching function. The new requirements and responsibilities that are being asked to teachers may not only mean an increased workload, in scope and intensity, but also can be the origin of conflict with academic activities, a source of fragmentation of time work and energy dispersion. Pressure to increase the workload was a factor indicated by 70% of participants in the survey.

4. New undergraduate profiles.

With the recognition of the strategic importance of higher education for economic and social development, new kinds of training are now required. These new profiles, (Neves, 2007), are demanding "flexibility, agility, alternatives for rapid integration into the productive system in constant change, which requires a rupture with rigid standards and models of training" (p.14). Thus, there are external demands for a predominance of university education focused on training, market-prompting new professional and teaching methods consistent with these new profiles, which, in turn, request a change of focus from teaching to learning, with consequences in terms of teaching practices more student-centered in learning to learn, problem based learning, learning doing research, interdisciplinary projects, collaborative learning projects, life long learning, creating the need for a change in strategy training of university and teacher training. The changes in objectives or even the design of what should be a university education, with the diversification of courses and training levels, with stronger ties to the labor market and concerns about the employability of graduates, eventually show a reorientation of the university's role in society and the functions and purposes of higher education and a reconfiguration of the organization of the university. So contradictory and multiple claims and aspirations are directed to the university as an institution and to the university education. A trend indicated by the literature is related to differentiation and segmentation of higher education with courses and curriculum offerings beyond traditional offerings and greater flexibility and options multiply study.

5. Pressure for quality and productivity.

The growing demand for quality determines the evaluation and accountability mechanisms that are driven to the universities, courses, academic activities, focusing on productivity . Those issues have impact to academic work and at the same time an increasing competitiveness among institutions. The implicit quality assumptions about the university seem to have fallen to the ground. Now quality is something to be assumed explicitly. Similarly, professors have to show that are able to do well, to perform its function well, satisfying the demands of society with maximum quality and efficiency. Regulation and standardization, certification assessment strategies appear to be related to quality assurance.

The pressures for quality, quality control mechanisms as a means of social control of the university, often linked to funding and regulation, eventually causing structural and functional changes in the university, changes in job training and curricula, focusing on academic work, and require a review of teachers' action strategies, greater planning efforts and documentation of their work, formal and administrative requirements, which can be seen from the viewpoint of partial loss of academic autonomy and control of program

development. The work of Askling (1997) and Harvey (2002) contains a vision that allows us to understand that the development of quality assurance processes required of students perform more administrative tasks and imposes a considerable workload. As Mancebo and Franco (2003) reported that a "metrics of institutional life (...) to get into the issues relating to tensions in teaching, a conclusion is obvious: the educational system that today revolves around the evaluation" (p.198-199).

The prospect is an "audit culture" as argued by Beck and Young (2005) when they cite Power (1994) and Strathern (2000), because, facing the performance criteria imposed from outside institutions requires the demonstration of the academic work relevance. Following the work of Freidson (2001), they argue about a sense of crisis and loss, and use the words of the title of the essay: "an assault on their professionalism" concerning the academic profession. The debate on quality control is generally seen by scholars as a threat to academic autonomy. Another relevant aspect is the struggle for visibility that is pointed to by Ball (2005), as the essence of performativity and its measurement technology.

6. Internationalization of the university.

Under different forms and with a global dimension in goals, in the function and work of the university in welcoming students from diverse backgrounds, implement adjustments to international standards, inter-institutional cooperation with international networks fellow members, international curricula, promoting mobility for students, creating international scientific networks develop e-learning or virtual universities. According Marginson (2000) the internationalization is related to a growth of relations between nations and cultures, and universities, in this respect, has a long history, partly because they have always been international in its orientation with respect to exchanges, cooperation and cultural exchanges. Prior to the expansion of graduate studies in Brazil, most of the Brazilian university professors held post-graduate studies abroad. Both the rise and consolidation of the Brazilian graduate programs were marked by the presence of foreign teachers. However, the internationalization context that takes new forms. Today for example greater international integration is important for postgraduate courses are well evaluated.

7. Development of application-oriented research.

The value of research aimed at solving problems, reaching the interests of the disinterested research, or academic products of high visibility, prioritizes short-term research at the expense of long-term research, with the consequent influence on academic autonomy. Licha (1994) following Weiler (1991) indicates that the process of transformation of the research has implications on academic autonomy, "understood as freedom to set the research agenda of an institution and also as regards the evaluation of scientific effort In general, the philosophical orientation of higher education"(p.46). Milton Santos (1999) analyzes the implications of this logic in the evolution of the role of academics, says that "the sage is replaced by the scholar, the scientist by the mere researcher, the professional intellectual, if not the major concern is over the meeting and teaching of truth, in all its forms, but a fragmented activity, dominated by an immediate objective or targeted to a reductive aspect of reality" (p.02).

Academics seem to be challenged by their work, before autonomous, now tending to be more regulated. A "research agenda" of the teachers seem to assume the logic of just-in-time knowledge worker, announcing a new kind of academic profile. At the same sense Leher (2004) makes a critique of the productivity and highlights the concept of academic capitalism that has characterized the university's agenda when he observes: "But it is necessary that the 'old' universities are convinced that this is not academic knowledge. The market requires an operational and pragmatic knowledge. In this context, technological innovation is inserted into the agenda of higher education on the capital periphery" (p.881). In this sense, another academic ethos prevails: one based on the market, with its notions of productivity, which can also lead to an institutional market ethos, but is relevant to understand to what extent these changes affect the academic profession.

THE NATURE OF ACADEMIC WORK AND ACADEMIC PROFESSION

University teacher are expected to be teachers ad researchers and the ideal is that both are intertwined in universities. Such ideal makes teaching and research the heart of the academic profession, as its core and represents the nuclear territory, with specific purposes or functions, and certainly specific skills. Community service (as called in Brazil - Extension) is the third element of the activity of a university professor and covers activities that enable linkages with society, cultural diffusion, services, dissemination of knowledge in order to make it socially available including linkage between universities and the productive sectors. Balbachevsky (2005) states that the two dimensions of academic work (teaching and research) and the conditions under which they perform differ relevantly in Brazilian higher education, as different institutional

settings impose vary greatly conditions for such activities. According the ideas of Altbach (2000, 2003) and Enders (2001) the author Balbachevsky points that the centrality in teaching activity has been documented in studies in different countries over the last decade, although it is possible to identify groups highly professionalized in research activity.

In other words, even the centrality of academic work is the binomial teaching and research, and teaching or extension to a greater or lesser emphasis in one or another academic activity, the changes undergone by the university should affect the academic work, promoting pressures in the daily work of teachers, the demands of productivity, and finally, in their capacity as teachers. If the university is changing, you may say that the academic profession also is. Where there was an academic profession or an academic career it may be drawing to multiple sections or reconfigurations.

University teachers are in an institutional field, a workspace, and therefore, act as specific actors in this space. They have expectations, ways of working, ways of acting and ways of perceiving change. Therefore it is necessary to consider the development in the setting or atmosphere of the work of the professor - space, time, organizational sets, classroom, and macro social space. The organizational context affects and is affected by the changes that act on the university and on academic work. Even teachers are able to develop mechanisms to strengthen their autonomy; it will be increasingly influenced by the institutional, organizational and social context in which this scholarly work develops.

Working in Higher Education is a social practice and depends not only on the decisions that institutions or teachers make, but is also broadly influenced, by the institutional context and the external environment. It is therefore important to understand how teachers perceive and respond to this changing context and demands of scholarly work seeking to clarify the connections between higher education policies, the changes they bring to the profession with the likely changes in the academic role that is expected of teachers, in the university practices, and finally in the reconfiguration of the academic profession. The possession of a specialized field of knowledge, formally certified by any educational institution and be under contract for a higher education institution or research center to develop one or more characteristics of occupational function, constitute what Grediaga (1999) claims for the minimum be considered an academic one: the field of knowledge practiced, the association of members of the organization in establishing a commitment to work and the scientific community that emerges from the process of sharing the central goal of research and make socially available knowledge. Basing their arguments on the modern notion of profession sustained by several authors, Grediaga conceives the academic profession as a particular type of profession.

The academic profession is consequently a special type of occupation dedicated to generate and transmit specialized knowledge, because even with the pressures for accountability, the increasing bureaucratization of the HEIs, the profession remains central to the university as the organizational space where the academic work happens and the interaction between members of the academic profession. Scholars differ in terms of its main activities in terms of knowledge areas (disciplines), type of institution to which they are linked - whether public or private, elite or mass, focusing on undergraduates' school or belonging to the category of research universities. Enders (1999), in a joint work with Teichler, displays important changes in higher education and the relation between the university and the society, involving the status, function and role of the university, reflected in the academic profession. Although these pressures are not a recent phenomenon, the university needs to know how to deal with the changes. Uncertainty, sense of crisis, decline, erosion, and marginalization, unstable context, are the words present at the academic profession and possibly revealing a loss of its fundamental characteristics. However, it is necessary, as argued Enders, investigate whether the changes and challenges of higher education will have a serious impact on the academic profession.

An important element of analysis is what Marginson (2000) names "deconstruction of the academic profession", indicating trends related to the loss of academic autonomy, considering the use of managerial practices (managerial approach to the administration), the increasing in number and importance, role of professional administrators, managers and technical staff rather than academic staff. It is a trend that leads to a centralized management of research with the partial weakening of departmental disciplinary identity, the creation of corporate programs at the margins of academic norms of international programs such as continuing education, graduate and corporate education, the increasing use of part-time work to meet emerging areas, leading to higher fidelity to the senior managers and less to the department or institution, the break of disciplinary structures and the creation of colleges (without departmental basis) for purposes of teaching or research centers or temporary projects, the subsumed research management systems for performance appraisal to allocate resources.

Indeed, what once seemed protected by traditions, institutions and values as academic freedom, intellectual integrity, and commitment to respond to social concerns, scientific autonomy and stability in the job, is now altered. Does academic freedom, so important to academics, will survive in these changing times?

Autonomy, job security, effective conditions to produce a work of quality, are conditions that make the academic work possible and the literature indicates that these conditions have worsened. Altbach (2009) criticizes the fact that the universities are being taken to a work with less autonomy to make decisions and to think, with priorities facing the government and market demands at the expense of traditional academic autonomy. He suggests that society would be better served by a more balanced academic environment in which universities might be more attuned to the wider public interest and traditional values of academic autonomy and independence.

The growth of global markets, the implementation of policies to reduce investment by the state universities, with the strengthening of applied research and technological innovation, asks for increased links between the university and the academics, with the market, and aim to search for external resources. The so-called academic capitalism (Slaughter & Rhoades, 2004) or what Leite (2003), calls the capitalist redesign of the universities is "a kind of institutional performance marked by the commoditization of knowledge, science and technology and the new management that favors private marketing and profit operations on the campuses" (p.5). The idea is that the universities can be transformed (and some already are) in universities and enterprises and be managed as they are, such with a vision of corporate (business view).

Occurs, then the enhancement of the entrepreneur academic, with the ability to seek external resources going to be as or more important than academic reputation. Thus, the academic productivity is then being measured by the number of publications and guidelines completed; the ability to mobilize external resources to finance research activities, the number of foreign publications (internationalization) and other indicators that the literature usually associates with academic productivity. The problematic issue is not the productivity, but the productivity-with its perverse effect named by Trindade (2001) as: "erosion of academic values (...) which is loosened gradually and dangerously, including its privatization by the internal increasing uptake of compensatory resources, as a result of the erosion of wages and the fall in research funding by government agencies" (p.163).

The intensification of teachers' work in higher education goes hand in hand with high productivity and the creation of paths for academic excellence is to become an entrepreneur and have several published works is more important than teaching. Academic publishing have become tasks in series, like pieces that flow down the mats an assembly line. The product is all that counts, not its reception. (Waters, 2006, p.42). In sustenance of this idea we point out the new production requirements, which express changes in the field of employment of university professors, for example, in the evaluation of post-graduate courses, with shorter cycle times and extend the working hours of advisors and researchers with strong pressures to publish in indexed journals, not to mention the bureaucratic demands of production statistics and reports and the strengthening of bureaucratic controls imposed by the state to academic life, often stifling the academic work, the search for funds to increase the visibility of the program graduate or department. There are references on the impact of changes arising from policies in the guidelines that the university adopt has consequences both in terms of ideals and the practices of research work, on time, promoting an acceleration of work, loss of autonomy over managing their time, involvement in short-term jobs and a growing pressure in terms of time.

With regard to the reconfiguration of the academic profession the direction is to redefine the set of functions and roles of university teachers, based on other parameters; redefinition of the academic career with an orientation toward adaptability to new demands, new realities and a university model and design of academic work in line with the political, economic, social, technological, demanded to the university, o affected what has been expected from the university and influencing its organization, structure and dynamics of their work.

CONCLUSION

The findings of this study about the multiple dimensions of academic life are proving to be consistent with a situation of growing complexity and increased workload, lack of resources, pressures to enhance research scores publishing more and more, as well as outside interference in academic work. Contradictorily teachers expressed their satisfaction with their profession even under the impact of policies and only 6.8% would never opt for an academic career. Although those pressures pressure they remain motivated by their work.

The teachers come with margins of relative autonomy that enables them to cope with the constraints of current policies and requirements and there is leeway for the exercise of academic work with certain limitations, but with quality (51%). For others there is no loss of autonomy and they remain in control of their time, intellectual production and the process of teaching. Yet others point out that there is a significant reduction in autonomy, in both research and teaching, due to the reduced margin of independent action that teachers today have to develop their work (21%).

However teachers experience dilemmas. The main dilemma is related to academic values, ethical and political commitments of the academic profession or further adjusts the exercise of their work to deal with challenges, changes and adapt (54%).

They adopt, however, the following conduct to the requirements and challenges posed by higher education policies: using strategies to avoid losing control of the work or to regain that control, trying to reinterpret the policies and requirements and adopt a strategic behavior in relation to them to "stay in control" their work and articulate viable ways (39%); use ways to escape the traps, or "neutralize" the impact of pressures seeking niches (32%); use strategies to deal with situations and trying to prevent damage and preserve focus on aspects of work that have meaning, then use survival strategies (22%) and only 6% indicate they have struggled to cope with increasing demands for greater productivity by increasing the workload and competition, feeling under pressure or "sinking" as they are not able to cope with these demands and pressures. Results are consistent with studies of Trowler (1998) who point out that academics are not passive agents of policies and therefore can reject the hypothesis that the massification of higher education leads to de-professionalization and proletarianization of academic profession.

We conclude with the words of Trowler (1998, p.55) as saying: "academics are clever people. Rebellion and innovation are strong and their forte .They frequently stand on strategic implementation locations on the staircase".

282 - Investigating Lecturers' Social Representations of University Assessment Policies: The Case of the "Enade" in Brazil

Ariane Franco Lopes da Silva[1] and Maria Angélica Rodrigues Martins[2]

Program of Post-Graduation in Education, Catholic University of Santos, Brazil
[1]arianefls@yahoo.com.br, [2]maria.angelica.rm@gmail.com

Abstract: This study discusses data collected from 50 university lecturers of different educational fields on their views regarding a national assessment policy in universities named Enade. Based at the theory of social representations, the objective is to understand subjects' conceptions of assessment and assessment policies and observe their impact on teaching. Two projective methods of data collection were used: the word association test and the production of a written message. The responses to the world association test were treated by the Software EVOC. The written messages were analysed according to the content analysis. The results indicate that representations contain elements that were contradictory. Some subjects associated Enade with its normative and political character, others with its formative one. This study contributes to the ongoing debate on government assessment policies and its implication to teaching.

Keywords: enade, assessment policy, social representations, teaching practice

INTRODUCTION

The subject of national assessment policies has been gaining space in the academic debate due to its potential for improving the quality of higher education in Brazil and elsewhere. As Martins (2010) have demonstrated, teaching and learning processes as well as the management of universities can benefit from a program of assessment that evaluates and regulates the provision of higher education. In Brazil, national assessments come at a time of great expansion of higher education. The author points out that from 1996 to 2009 the number of private institutions increased from 211 to 2069, while the number of state institutions increased only from 211 to 245. As a result, almost two thirds of graduate students were, in 2009, attending courses at private institutions.

As a consequence of this expansion, issues regarding quantity as well as quality of education are at the forefront of the academic debate (Ristoff & Giolo, 2006; Verhine, Dantas & Soares, 2006; Brito, 2008). In this process of expansion, a national evaluation program was thought to guarantee a qualified higher education system and to facilitate regulatory actions.

The relevance of the issue of institutional assessment in this particular moment can be found in the constitution of the Sinaes (National Higher Education Evaluation System – Federal Law 10.861, April 14th, 2004), put into practice after a long debate with segments of the education community. Take part in the Sinaes three assessment instruments, applied in distinct moments: an assessment of the courses through instruments and proceedings that include *in loco* visits by an external commission; an assessment of the institution by an auto-evaluation process, coordinated by an internal commission and by an external commission designated by the Inep (National Institution of Educational Study and Research); an assessment of students performances and achievements named the Enade (National Students Performance Exam). The Enade proposes to evaluate undergraduate learning processes and academic performances and achievements in relation to knowledge and competences predicted by the DCN (National Curriculum Directives) for each graduation course. It also evaluates students professional competence and skills and their knowledge of the current facts in Brazil and around the world. In order to do that the exam is applied to graduates at the first academic year and to those concluding the course. A complex set of calculations using these scores generates an index which is thought to indicate the level of progress attained during the course. The results of Enade count in the overall assessment of the university, having an effect on its ranking.

The Sinaes has in its directives a commitment to the formative character of assessments, to the integration of internal with external assessment processes and to the recognition of the diversity of the higher education system. It has also maintained that teaching and managing staff, students and representatives of segments of civil society will all participate in its processes and that all data will be made public.

Although this national evaluation program has many qualities and potentials, segments of the education community have been pointing out some of its fragilities. The critics emphasize that, in a general sense, they tend to legitimate universal knowledge, excluding from curriculum knowledge that reflects the ways of

living of communities (Garcia, 2010). Students have also been demonstrating their views against the Enade and it has been detected some resistance to participate in it (Leitão, et al. 2010).

At the core of the debate seems to be the difficulty faced by the academic community to translate policy directives into practice and to deal with the conflicts that can emerge out of this process. As we have seen, this translation is not a straight forward process since it is dependent on people's perceptions and understandings of assessment policies, their procedures and objectives. With Dias Sobrinho (2005, 2010) we can see an analysis of the reason why education reforms fail to succeed. According to him, the education community, especially teachers, feel distant from proposals that were usually made by politicians. They do not take part in the debate neither internalize their concepts. As a result, teachers see these policies as having little effect.

THE STUDY

In order to understanding how assessment policies are perceived and understood by university teachers this study aims to look at their social representations of assessment and Enade, and observe their impact on teaching practices. It finds in the theory of social representations, idealized by Serge Moscovici (2008), the theoretical and methodological support for its development. Since representations are thought to guide people's attitudes towards a subject, it is important to investigate lecturers' views on assessment, as a means to understand their positions towards it and the use they make of it on teaching. The aim is to identify the elements that constitute social representations of assessment and of Enade and observe how they determine attitudes towards this national assessment program.

In his seminal work, Moscovici (1978) was primarily concerned with how scientific knowledge was communicated and disseminated in society and how it was transformed into common sense. Contrary to the wide thinking that scientific knowledge has more value than folk knowledge, Moscovici shows how they are in fact closely interrelated at the point of coexistence. He demonstrates the power of this interrelation stating that when folk knowledge is successful, they "enlarge science by transforming it into a new common sense" (Moscovici, 2001, p. 12). Therefore, for him, social representations are about folk knowledge, common sense and know-how and that this modality of knowledge is in fact knowledge on which important decisions are based at.

But how is this common sense produced? Firstly, it is not a result of individual thinking, but a production of "*thinking societies*" (Moscovici, 2001, p. 12). The author points out that this production takes place in all forms of groups and communities such as clubs, public spaces and associations. These representations are acquired during the normal course of our lives, without specific training and through dialogue. It is in this sense that representations are thought to be "*discursified thinking*", that is, they involve language and conversations (Moscovici, 2001, p. 29).

As Moscovici has demonstrated, the reason why we make representations is to transform the "new" into something familiar. Once in contact with new individuals, ideas, cultures or objects we produce representations of them, that is, we give them a name and associate them with images "so as to feel at ease with it" (Moscovici, 2001, p. 20). According to him, representations are reconstructions of the "new" within a context of believes, norms, notions and values in which it has now entered. Fitting the "new" in the already existing notion is an act of classification. Therefore, when we name something, we give it a quality or subscribe it into a category. It becomes, then, easier to talk about the "new" in terms that all members of that community can understand, since the category in which it is subscribed is conventionalized. In the end, representations allow people to understand reality through their own system of references, they bind people together, guide and orient their behavior.

However, if circumstances change, what happens to representations? A number of studies have been developed in order to answer this question. The Theory of the Central Nucleus of representations proposed by Jean Claude Abric explains how representations are constructed and transformed. For Abric (1994), representations have a centre or nucleus, which is its main part. Around this centre, one finds the peripheral elements. The centre is associated with collective memories, being consensual and resistant to changes. There, one can find the elements and attributes that define the representation, organize and give it a stable character. The elements that compose the nucleus express the homogeneity of the social group and guarantee the maintenance of representations.

The peripheral elements, on the other hand, are more sensitive to the immediate context and to individual experiences. They express the heterogeneity of representations, and it is for this reason that they may contain contradictions. Their function is to incorporate new information that is likely to threaten the nucleus, allowing transformations to take place in its elements.

Abric (1994) explains that, if individuals perceive the 'new" situation as reversible, new attitudes may be incorporated in the old causing modifications to the periphery of the representation. However, its centre remains stable and unchanged. If individuals perceive the "new situation" as irreversible, new attitudes will have greater impact in the centre, changing the representation. The author points out that it is not enough to identify the elements of representations, but to understand how they are interconnected and arranged around the centre.

People's conceptions of Enade and teaching may find resonance in the way they understand assessment processes. Therefore, access their social representations of Enade, that is, understand how it enters a group of already existing categories of assessment by observing how it is classified, named and talked about, can inform the academic community and policy makers about people's attitudes towards the exam.

In order to investigate these representations this study found support in the theory of social representations and on the analysis developed by Abric (1994) on the content and structural arrangement of the elements that constitute the representations. It aims to contribute to the understanding of embedded positions of acceptance and resistance to national assessment policies, reinforcing the ongoing debate on this subject.

Population

This study discusses data collected from 50 university lecturers in Education (Pedagogy), Mathematics, Biological Sciences and Humanities of three private universities in São Paulo. The group was formed by 22 female subjects and 28 male subjects. On average these subjects aged 47 years.

Method

Two projective methods of data collection were used: the free association test and the production of a written message. In the first, subjects were told to evoke five words that came to their minds in response to the following terms: assessment; Enade; Enade and teaching. The responses to the free association test were treated by the Software EVOC (2000) based at Vergés (1992). The free association test is known to facilitate access to the elements that constitute representations and allow the observance of their structural arrangements. Its spontaneous character also facilitates access to words ready available in mind, related to the theme being investigated.

With the written message instrument, a sample of 25 subjects should reply to an email sent by a friend from another university, whose undergraduate students had not participated in the Enade. Subjects were asked to express their views on Enade, because those students wanted to know more about its potentials and fragilities. Subjects were given a model message to follow, with blank spaces to be filled in. In these messages they should specify how they saw the implications of Enade to three distinct agents: university managers, lecturers and students. The written messages were analysed according to the content analysis (Bardin, 1977). This instrument was thought to facilitate the expression of representations, since it enabled subjects to communicate their opinions in a projective manner, by removing themselves from their immediate work context.

RESULTS

The EVOC combines the frequency of evoked words with their sequential order, generating four possible groups, producing a table. The words highly frequent and promptly evoked can be found on the top left quarter of the table. They are thought to contain the nucleus of the representations. The words highly frequent, but not promptly evoked, can be found on the top right quarter of the table. They are thought to display the intermediary elements of representations. The same happens with the words appearing on the left lower quarter of the table. They are the words with low frequency but evoked first in the sequence. The ones with low frequency and not promptly evoked are kept in the lower right quarter. The responses to the world association test following the term "assessment" generated four groups (see table 1).

Table 1: EVOC – term "assessment"

Frequency	Mean order of evocation	
	Fewer than 2,5	More than 2,5
Above 5	26 test	10 knowledge 20 score
From 5 to 8	5 checking	5 be afraid 5 value 6 development 8 learning

The word "test" probably constitutes the main element or the nucleus of the representation, indicating that it is the most crystallized and stable concept of assessment or attribute given to it. The upper right and the lower left quarters contain the words that may constitute the intermediary elements of the representation. These words tend to confirm the elements found in the nucleus. In fact, the word "score" is related to the word "test", in the sense that it corresponds to someone's performances in a test. In the lower right quarter it was found the words conveying individuals' feelings and experiences related to assessments. The expression "be afraid" may indicate a negative experience with assessment, nevertheless, the words "learning" and "development", which were also in the same group, have a different meaning. They convey assessment's formative feature. As Abric (1994) pointed out, the elements at the periphery may contain contradictory elements since they express individuals' own experiences in relation to the theme being represented.

The responses to the world association test following the term "Enade" produced the following table (see table 2).

Table 2: EVOC – term "Enade"

Frequency and Mean order of evocation		
	Fewer than 2,5	More than 2,5
Above 6	6 bad 7 not organized 9 student	7 criteria 8 score 12 official
From 3 to 4	3 fragile 3 statistics 3 development 4 lie	4 marketing 4 quality 4 standardize

In the upper left quarter the word "student" indicates the main agent of this assessment program, followed by the words "not organized" and "bad". They would constitute the nucleus of the representation of Enade, indicating a critical position towards the exam. In the upper right quarter, the word "official" may indicate Enade's normative and political character, while in the lower left quarter it is possible to see the attributes "fragile" and "lie", probably indicating a critical view towards the exam. In a sense, these words support the ideas expressed in the first quarter. The word "statistics" may confirm the normative and political character of the exam. In the last quarter, the words marketing and standardize expressed a concern with the use of the exam for marketing, ranking and competition among institutions, once the results of the exam are made public. However, the word "quality" may be related to one of the purposes of assessment programs, which is to guarantee the quality of education being offered by institutions. The word quality contrasts with marketing and standardize, pointing out the co-existence of different views about Enade. It could also demonstrate that the Enade constitutes a reference to the wider public of the quality of the institution.

The responses to the world association test following the term "Enade and teaching" can be seen in table 3 below. In the upper left quarter the word "useless" expresses the idea that the exam has no impact on teaching for these subjects. In the right upper quarter the word "senseless" also indicates a critical view of the exam and the lack of significance for teaching practices. In the lower left quarter the word "confused" together with "quality" may indicate contrasting views about the effects of the exam on teaching. The word confused may show that the objectives of Enade are not clear, while the word quality expresses one of its objectives. The word "relation" may be expressing some correspondence between the exam and teaching. Finally, in the right lower quarter of the table the words "knowledge", "criteria" and "objective" seem to indicate, for few subjects, a concern for the impact of the exam on teaching and the objective of the exam seems to be the main element of concern.

Table 3: EVOC – term "Enade and teaching"

Frequency	Mean order of evocation	
	Fewer than 2,5	More than 2,5
Above 6	6 assessment 13 useless	6 senseless 6 official-politics 7 revision
From 3 to 4	3 confused 3 quality 3 relation	3 knowledge 3 criteria 4 objective

What these results suggest is that, while the representation of assessment is mainly associated with tests and scores, words like knowledge, development and learning, indicate a dialogue between conventions and

individual experiences. This dialogue may imprint new elements to the conventionalized nucleus, accommodating formative attributes to the representation of assessment. With the term Enade, on the other hand, fewer contrasts were observed between conventions and individual experiences, since almost all elements in the table were expressing a critical view of the exam. The same could be said about the third term "Enade and teaching", and subjects did not see any effect of Enade on teaching.

After having observed the structure of representations, the next objective was to look closer at subjects' views of Enade in relation to three university agents. Data obtained with the written messages were organized in three tables of content, each concerned with the implications of Enade to these different agents: university managers (table 4), university lecturers (table 5) and students (table 6). Each table shows how segments of messages were distributed in categories according to the most recurrent themes. Some segments were classified in more than one category.

It was possible to see in table 4 that the topic of Enade and its implications to university managers were more commonly associated with the idea of being an instrument for administrative actions (Cat. 1), involving changes to teaching staff and changes to educational policies: "…it promotes changes of teachers" (subj. 1). It was also common the idea of Enade having a political and a regulatory character (Cat. 2): "Punish, classify and sometimes unqualify" (subj. 12); "imply conformity to convictions of those that have State power" (subj. 8). In category 3, we find references to the use of the exams for marketing purposes: "Usually serve to advertise the institution in the media" (subj. 16); "represents financial success" (subj. 17). Responses classified in category 4 emphasized the fact that the Enade shows the state of affairs, how things are at the present moment: "serve as an index" (subj. 1); "shows a reality" (subj. 15). In category 5, it was found references to its implications to the assessment of both teachers and students: "Assess students directly and teachers indirectly" (subj. 29). Lastly, category 6 grouped ideas that associated Enade with an instrument to measure the quality of education and a means to evaluate educational practices: "serve as means for necessary changes in his course" (subj. 2); "serve as corrections of pedagogical aims and objectives" (subj. 5).

Table 4: Implications of Enade for institution management (total of 29 occurrences)

	Cat 1: Administrative changes	Cat. 2 Negative aspects	Cat 3: Marketing	Cat. 4 Reality	Cat. 5: Assess teacher, student	Cat. 6: Pedagogic changes
managers	7 (24.13%)	7 (24.13%)	5 (17.24%)	4 (13.79%)	4 (13.79%)	2 (6.89%)

The most frequent category in table 5 (implications of Enade for lecturers), was category 1 where it was found references to the fact that the Enade offers a feedback of what was taught, of students development and needs, suggests points to be reinforced and what changes should be made: "Feedback of what was touched during the course" (subj. 2); "signalize changes and improvements of pedagogical practices and learning content" (subj. 5). Category 2 associated the results of Enade with lecturers' teaching competence: "represents an indirect measure of competence" (subj. 11). Category 3 classified responses that were critical of Enade suggesting that it had little implications to teaching and to students' development: "Hasn't changed anything" (subj. 22); "Doesn't help us dealing with anxieties and expectations in relation to the course and profession" (subj. 21). In category 4 we found sentences expressing a concern with the adaptation of classes and curricula to fit the exigencies of the exam: "Demands preparation for the exam, which does not translate into the needs of the class" (subj. 12), and in category 5, the idea of the teacher being in an intermediary position: "Intermediary in the process" (subj. 20).

Table 5: Implications of Enade for university lecturers (total of 26 occurrences)

	Cat. 1 Feedback	Cat. 2 Teacher competence	Cat. 3 Negative aspects	Cat. 4 Adapt to the exam	Cat. 5 Teachers as intermediaries
lecturers	10 (38.46%)	7 (26.92%)	5 (19.23%)	3 (11.53)	1 (3.84%)

It was possible to see in table 6 (implications of Enade for students), two contrasting ideas. In category 1, subjects expressed their views that the Enade evaluates students' learning and development: "evaluates them technically" (subj. 29); "assess learning" (subj. 13); "academic self-evaluation" (subj. 5). In category 2, on the other hand, a similar

number of subjects stated that the Enade had little or no value to students, emphasizing its political aim: "waste of time" (subj. 12); "Exam does not reflect learning" (subj. 21); "Instrument for regulative and extra-curricular purposes" (subj. 11). Category 3 pointed to its implications to the image of the institution once its results became widely available: "indicates the result of the university" (subj. 25); "projects the image of the university" (subj. 18); "Allows comparisons to be made" (subj. 26). In category 4, subjects were concerned with the impact of the Enade to their job prospects: "The score may result in being or not accepted in the job market" (subj. 27).

Table 6: Implications of Enade for university students (total of 26 occurrences)

	Cat. 1 students learning	Cat. 2 No value to students;	Cat. 3 university quality and image	Cat. 4 future work (career)
students	9 (34.61%)	9 (34.61%)	6 (23.07%)	2 (7.69%)

It was possible to see that for subjects, Enade assumes different attributes depending on the agent being considered. It was an instrument for administrative and regulatory actions for university managers and a feedback of what was taught and learned for lecturers. As far as students were concerned, Enade could show their learning progress for one third of subjects. For the other third, Enade had no value.

CONCLUSION

The objective of this research was to identify the representations of Enade and try to understand subjects' attitudes towards this national assessment program. Since representations reconstruct the new within a set of existing believes (Moscovici, 2001), the aim was to observe how the representation of Enade, which is a relatively new program, is being accommodated and reconstructed within a set of believes that subjects already have about national assessment programs. The identification of the elements that compose the representation of assessment would contribute to the understanding of attitudes of acceptance or resistance of Enade.

It was possible to conclude with the free association test, in relation to the term "assessment", that although subjects associate it with a test, which has a punctual characteristic, learning and development are words that refer to a process and have a formative character. In this sense, these peripheral elements probably indicate a new attribute to assessment and a possible attitude of acceptance of assessments.

In relation to the term "Enade", "bad" and "not organized" were very much associated with other elements linked to State and politics. The words "official" and "statistics" support this association. Compared with representations of assessment seen earlier, there seems to be a strong rejection of the exam itself, emphasizing its normative character instead of its formative one.

As far as the term "Enade and teaching" was concerned, subjects strongly rejected any connections between them. This is an interesting result since learning should be associated with teaching and Enade is supposed to reflect learning. The link between Enade and teaching has not been established here. Nevertheless, in the message instrument, subjects apparently seem to point to positive implications of Enade to teachers and teaching. The word "feedback" may indicate this implication. When removed from their immediate work context, subjects seem to have a more positive image of Enade. This result probably indicates that representations are being formed and in this process it is possible to find contradictions in attitudes of resistance and acceptance.

These results can inform policy makers about the need to act so that teachers are informed about the significance of national assessments and that they are seen as important agents in assessment processes, guaranteeing active forms of participation in them. The translation of policy directives into practice could be facilitated if the distance between proposals and university agents were shorten.

304 - Monitoring Student Progress System - A Portuguese Discussion Proposal

Júlio Diamantino[1] and Eurico Lopes[2]

[1]Agrupamento de Escolas Afonso de Paiva - Castelo Branco, [2]School of Technology, Polytechnic Institute of Castelo Branco, Portugal,
diamantino1968@gmail.com, eurico@ipcb.pt

Abstract: Progress Monitoring is a method that measures and evaluates a student academic performance. This method can be applied to an individual student or entire class. To implement this method targets to be achieved by the student or class, are established following students' scores which are compared regularly. Based on these ratings changes in the method of study to improve student outcomes are made. This system is common in UK, as Anticipatory Classifier System and Pastoral Systems.

In this paper we propose to make the analysis for a Progress Monitor Systems discussing the ethical and legal constrains in Portuguese system. We discuss also the technological, functional and back-office requirements to implement a prototype progress monitoring system.

Keywords: Anticipatory Classifier System, Pastoral System, Portuguese Education System, Data Warehouse

INTRODUCTION

This paper describes the initial study to implement a *Progress Monitoring System* (PMS) in the *Agrupamento de Escolas Afonso de Paiva – Castelo Branco.* PMS is a general model that defines quantitative objectives to the student and keeps up with them, monitoring his development.

Nowadays the Students Evaluation System Records are still restricted to register both, qualitative and quantitative, students' grades. In the last few years the Portuguese Education Ministry advanced to the treatment of this information, elaborating reports which are afterward sent to schools. The analysis of this system does not answer the following research questions: "Is it possible to predict a student's long term grade?" and "Will student school performance increase with the definition of goals?" Due to these questions, in which ways can the organization adopt practices that provides the improvement of students learning skills. This paper shows the developed work: beginning by defining what a PMS is and what the pre-requisites are to implement the model in a Portuguese public school. Afterwards there will be made a brief analysis of the research model used and the reasons for its choice to this research project, ending with the presentation of a conceptual model.

WHAT IS THE PROGRESS MONITORING SYSTEM

The Progress Monitoring System aims improving student academic results. To achieve this goal the student must be aware of the goals, be stimulated and embedded in defining them to evolve and increase their abilities. There are two different concepts that can be applied to this model: *Proximal Developmental Zone* (Vygotsky, 2006) and *Progress Monitoring* (Monitoring, 2010).

Vygotsky's work (Vygotsky, 2006), include some concepts that have become unavoidable in the learning development area. One of the most important one is the *Proximal Developmental Zone*, that reports to the difference between what a child can do by herself and that what in spite of not being able to do it by herself, is able to learn and do with the help of a more experienced person (an adult, an older or more advanced learning child, for instance). The *Proximal Developmental Zone* is therefore all that a child can acquire in intellectual terms when given the suitable educational support.

Progress Monitoring (Monitoring, 2010) is a method that measures and evaluates the academic results and the implemented actions. This method can be applied to an individual student or to a class, starting with the definition of goals for a student or class. During the process, students' grades are compared on a regular basis. Based on these evaluations, some changes are introduced in the study method in order to improve students' results. The major benefits of this system are:

- Fast knowledge acquisition by receiving more direct instructions;
- More privileged information;
- Students' progress documentation to improvement proposals;

- More communication efficiency with the students family and others about the progresses made.

The student's progress monitorized must result from an articulated work between parents, teachers, students and psychology services, so that everyone takes full responsibility in achieving the defined goals.

The time in the analysis must be considered, due to several factors that can occur to second and third level students, like: the entrance in a teenager period; the curricular changes when entering the seventh grade and also some psychological factors such as the passage from concrete thought to an abstract one. This application may also identify some failures, not only in the curricular path determined by the school but also in the intermediate curriculum.

WHICH COUNTRIES USE THESE MODELS

The use of the information regarding the use of students' academic path in defining both individual and group goals already exist in some Anglo-Saxon countries. Therefore we present a more detailed study relaying in the English model, according to the following reasons:
- Both cultural and social proximity;
- A consolidated system analysis;
- Presence in Portuguese schools of a British matrix.

It's our belief that constrains and limitations that might be associated to the implementation of this model will be easier to detect and solve.

From the analysis made to the English model we emphasize some particular aspects that we consider to be relevant to this project, such as:
- The transition is made essentially by ages and not by approval;
- The govern finances the families in their choice of schools;
- There are *Local Education Authorities*, tied to the counties, which administer all level schools.

The educational system in England is organized as follows:
- Primary phase - pre-school education, in ages between 2 and 5 years old, divided in playgroups and nursery schools;
- Compulsory education - begins in the age of 5. The average age in transition to a secondary school is 11 years old (the compulsory ends at the age of 16, although many students remain in this phase after this age);
- Secondary phase - Sixth form colleges.

In 1988 a national curriculum was introduced in British schools with the purpose of spreading, balancing and improving the school program bringing more coherence to the school system. The curriculum defines what the students must study, what must be taught and the standard goals to achieve. This element is considered the most relevant for our study. The English national curriculum is divided into 4 Key Stages (KS) containing 3 core subjects: English, Mathematics and Science and 9 "non-core foundation subjects" (Agency, 2010). The KS are related with the ages - one of the great differences between the English system and the Portuguese one. The KS1 goes until seven years old; KS2 from seven to eleven years old; KS3 from eleven to fourteen (pre GCSE) and KS4 from fourteen to sixteen years old (GCSE preparation and professional qualifications equivalences).

The more common age for students to be transferred from state primary to state secondary schools in the United Kingdom is at the age of eleven years old, where no type of exam has to be done. To be admitted in the independent state schools, one has to pass a Common Entrance Examination, at the ages of eleven, twelve or thirteen years old (Agency, 2010).The introduction of a national curriculum has made possible the implementation of Standard Assessment Tasks (SATs), where students are evaluated in several stages during the compulsory school. The SATs are used to evaluate the national results from the outside, complementing the teachers and the school inside evaluation. After the first 3 Key Stages, in between seven and fourteen years old, students are evaluated in languages, mathematics and science through tests, tasks and the teachers' evaluations national wide. The results are then published for each student, each school as the national averages for comparison purposes. By the end of Key Stage 4 (sixteen years), the General Certificate of Secondary Education (GCSE) exams are the main evaluation resources. The GCSE's are the standard qualifications for practically all students in the United Kingdom. The new A level, obtained from a 2 year studies period, between seventeen and nineteen years old, is entirely based in a modular logic, in which

students can complete modulus as they advance in their studies instead of making a final exam (Agency, 2010).

Due to the description made above of the English Education System, we now point out some important facts, such as:

- Students and mainly their families are free to choose their school;
- The students curriculum is established according to a sample of core subjects and some optional ones which allows students to have an enormous flexibility in the education range;
- Student's evaluation is made basically according to the GCSE.

These factors lead us to a wide range in terms of education offers and to a school culture that involves and relates students, families, teachers and all the community. This enrolment leads schools to modern practices such as tutoring services and a much used program named Pastoral System (Agency, 2010). This program, functioning in several schools, has the following characteristics:

- Elevating students expectations;
- Long term preparation;
- Involving all the community;
- Goals definition for each evaluated subject.

Applying a Pastoral System implies two aspects: A first one, linked to a more pedagogic of the institution organization and a second one, more technical and tied up to the implementation of a computer information system. We now present an example of both.

PASTORAL SYSTEM CHARACTERISTICS

A pastoral System is a model that implicates all the education community in the student academic results. It's a system of responsibilities and tasks divided within the members of the community. Students are given a Tutor that accompanies and follows them during their academic path. The following graphs show some already implemented.

Figure 1: Pedagogical Coordination Team (Plunkett)

Figure 2: Monitoring Team (Plunkett)

Head of Year or Learning Manager: Responsible for a team; Accountable for large group of pupils; Discipline; Pupil welfare; Liaising with parents; Linking with other agencies and support.

Group tutor: Responsible for group; Pupil welfare; Discipline Liaising with parents and Head of Year; Monitoring individuals development, emotionally and academically; Motivating and inspiring pupils as a positive role model.

Goals: Establishing defying goals; defining non-predictable goal; aims; achieved with hard work, positive attitude and whiling to learn; evaluation record and goals comparison; records at the beginning and end of the school year; reporting to parents.

In the English market there are computer applications that in a wider or restricted way record data from pastoral system starting from goals bases to achieve. Afterword applications are presented and their main characteristics are related with PMS.

RtIProgress Monitoring System: Program that measures the evolution and documents the student's academic progress during a time period.

Characteristics: Record and monitor (permanent computer data records); SMART goals; Behavior Success Plans and Manifestations; Compare Test Scores (Classes, Grade Levels); Import Student and Staff data; Import State / District Test Scores; Export Test Data; Monitor ascending or descending, subjective or objective goals; Create individualized and specialized goals and District/Site Level Testing Utilize Curriculum-Based Measurement and Scientifically Based Research; Interventions;

School Software Company com (Company)

Characteristics: online behaviour tracking system Supporting Students- behaviour tracking allows selecting the most appropriate interventions for an individual, building an action plan and monitoring its impact. Detailed and objective information is also vital if schools are to involve all the relevant stakeholders in the process of effective student support; Staff Development- all members of staff can analyse behaviour, select appropriate interventions and then monitor their impact.

Advanced Level Performance System (Alps)

The Advanced Level Performance System (Alps) is a nationally used A level, AS level and BTEC National analysis and training package for delivering quality improvement in schools and colleges.

Characteristics: Complete service from analysis to training; Tool for improvement; Spreads good practice for long-term; Practical training; Easy to submit data; Dedicated helpline service; Aspirational systems.

EduTrack: (Ltd.) Software for student progress tracking and reporting to parents

Characteristics: Real time access to assessment data and reports for staff, students and parents; **A**nalyse student assessment data and identify underachievement or lack of progress; e.g.; Monitor students' progress against targets and instantly measure distance travelled; Measure the progress of groups and individual students between two points in time; Compare the performance of a specified group of students in different subjects; Perform value added or whole school/college grade distribution analyses.

 Learning Plus UK -Level 2 & 3 Tracking

Level 2 and 3 tracking tool for the use of the members of the Berkshire Plus and London Plus projects. The software allows to track and monitor the performance of students 16-19 taking Level 2 and 3 qualifications, including A2 and AS levels, GCSE Maths and English re-sits, BTEC First Diploma qualifications, OCR Nationals and the Certificate in Childcare Education (CCE). Data is input for each student and an average GCSE score is produced which is used to generate a minimum target grade. The target grade can be set at different percentiles to allow for aspirational target setting (e.g. at 50th, 60th, 70th, 80th, 90th percentile). Student progress is monitored so that early intervention and support can be implemented if they are not on course to achieve their target grades. The software also gives a value added score. The software also looks at both students who have achieved their qualifications and those who either did not succeed or withdrew from courses.(UK, 2011).

The use of these applications does not emerge isolated, in the analyzed cases this information become available according to the following steps:

- On a first meeting between students, parents and psychology and guidance services the students' curricular data of the student is made. On this meeting the students academic path is analyzed, identifying which data must be processed in the application.
- Next step is introducing data in the application; this one generates an odd in getting a certain level. Based on the obtained data, the psychology and guidance services, creates a set of goals. These goals are not predictions are calculated, from the obtained grades from students between KS2 and KS4. The purpose is that the goals can be achieved with hard work, positive attitude and whiling to learn.

Example:

My odd in achieving each grade is:

- A*   **11,8%**
- A   **22,4%**
- B   **28,8%**
- C   **28,2%**
- D   **7,3%**
- E   **1,2%**

My minimum grade is **B**

My goal grade is **A**

After this stage a work plan is created, that contains not only the tasks to be developed by the several process members (student, Parents, Teachers, Psychology and Guidance Services and School). Regular meetings are also programmed with all members during the evaluation cycle.

Portuguese Case

Regarding the existing applications existing in Portugal and according to the certificated software list given by the education department, available in their site, to register and analyze the students' curricular data, we cannot find in non of them neither in their whole modules that perform these kind of operations. These applications only register personal and curricular data not making any kind of statistic evaluation whatsoever.

RESEARCH METHODOLOGY

To implement such a system presupposes the school community <u>participation</u>. In this way, we intend to develop a prototype in a pilot school to identify not only its technological but also organizational requisites. With this prototype we want to indentify if it suits the organization and the educational process.

The project is in its initial stage; therefore the adopted research methodology is action-research, in which the aim is to check out the adequacy of the monitoring student progress system to a pilot school.

To Kemmis and McTaggart(1988), to apply action-research means to plan, observe, act and thoroughly, in what we do in our daily experience. Just like its name implies, the action-research looks forward to make changes (action) and comprehension (research). The consideration of these two dimensions, changes and comprehension, can give an important contribute in the elaboration of the research project. The purpose in this study is that the program fits and has good results. Therefore, all members of the school community must be involved in a way to understand the demanded result. In this case the action-research method has become the most suitable for the project in course.

One of the advantages of this process refers to the literature review. In action-research case reading is much more directed to project results. It's necessary to consciously find relevant works, which contribute to information analysis. The result will be a literature review established by relevance and not by subjects or contents.

Besides that, this process allows changes in the project. If the information's points towards goals reviews, new aims, strategies or action methodologies, that may be really important to the contestants and the future actions to be developed.

The first question to be done may be the following one: What can be made to improve the student's academic results? In this way we intend to: Improve the implicated practice through its comprehension of the education practice; the condition where practice is produced; involve and guarantee that all members of the process take part in it; to insure the participative process organization in a way that all parts can produce effects; to allow that all members commit with the change.

In action-research, one can substantially improve work accuracy by combining the information collecting, the comprehension and literature review. In this case, it's important to obtain information from the following matters: What are the student's goals? Is it possible to quantify these goals? Which were the main advantages in defining measurable goal? And disadvantages? Which school term could be our methodology object? At what age should one initiate this methodology? Which psychological social and ethical could one use in this methodology? Are Portuguese students ready to deal whit this king of system? And what about the school community? From where can immerge some kind of resistance to this type of methodology? In which areas the goal definition could have greater importance to improve student's results? In what way one can one make these data available so that the support services can be improved in detecting students difficulties? Implementing this system is possible with this transition regimen or should it be changed to an evaluation

system externally regulated? What evolution student's data have during the study term? How do the several members of the education process participate in it? What is the main purpose of the several educations? One way to answer this questions is mainly based on interviews with various players in the educational process, in consultation with relevant legislation, not only students but also the protection of personal data in general, the existing data collection at school origin the systems computer or on paper registration. Where are some ways to collect information: Summaries of meetings, notes made by the researcher; interviews with staff involved with the project, reviews project actors; documents prepared earlier; applicable legislation and model cases application. To avoid the effects of excessive subjectivity, these techniques were combined to collect information with other, traditionally more objective questionnaires and semi-structured interviews.

It was necessary to consider the degree of participation of the staff involved in the project. There are person who cannot be excluding in an action-research, are called stakeholders. For every decision and action, the stakeholder is someone who can be influenced or may influence that decision or action. According to Uhlmann(1995) their participation is fundamental: They are familiar with the situation and can clearly identify the main elements; know the story, they can say what was done and what may be culturally problematic, are able to assess appropriateness of possible solutions to certain problems, continued in the group or community after completion of the action-research; Your relationship will contribute to the implementation of actions.

In this project we can identify as stakeholders, the Group Director-Implements all of the strategic guidelines of the school; Pedagogical - defines the educational goals of the school, coordinator of tutors – Coordinates the activities of the various classroom teachers and by this means the connection to Carers, Psychology and Guidance Services (Psychologist) - Key element in setting targets for his knowledge of the school population;

This project identifies the following groups or individuals: Ministry of Education - Sets the national education policy, sets general goals for students to study, validate and certify applications that use data curriculum for pupils; National Commission for Data Protection - validates and records the database containing individual data, the Group Director - Performs the directives issued by the Ministry of Education and the Pedagogical Council, a key part in implementing the model to bring together expertise and resources for its implementation; Pedagogical – Sets the educational goals of the Group with reference to the guidelines of the Ministry of Education and validate the teaching methods and resources for the feasibility of the actions of the model; Psychology and Guidance Services (Psychologist) - Responsible for monitoring all students, a key not only the definition of the model to implement due to their psycho-social knowledge as "know-how in education policy, in implementing its role redouble its importance not only in setting educational goals and in evaluating the implementation of those measures; Coordinator Director Classroom teacher - assures the link between educational bodies and the classroom teachers, and essential in the transmission of information between decision makers and performers; Class Director - Ensure the link between the school and the Guardian, and its fundamental role and not only in presenting the model as well as in monitoring their implementation; Teachers - Your participation is critical in implementing the model as these ensure that the acquisition of knowledge of students; Administrative Services - They must ensure the registration of all documentation the model; Carer - Your involvement is essential to achieve the objectives, should be heard, informed, involved and accountable in all the process to also take ownership of it; Student - As a last resort, are the main actor, the whole model works around him and to him the motivation to maximize their school motto and the whole model.

This method is based on a set of assumptions and in terms of definition, both in terms of implementation that we will mention: In terms of defining the model we have the following assumptions: Existence of computerized student test scores; access students' grades in the current information systems; Authorization steering Group to carry out the feasibility study of the model, there are no legal impediments that impede in any way in whole or in part any phase of the model, the level of implementation of the model have the following assumptions: Concordance of student and the Guardian; Anonymity of student curriculum data in the definition of Base profiles; Involvement of Psychology and Guidance Services, teachers, classroom teachers and Administrative Services in the model.

The implementation of the Progress Monitoring System can raise a number of issues which follows: Use of personal data, Use of the students; Provision and use of data electronically; Setting targets for students; Register of goals in computer system; Plans for cognitive improvement; The issues mentioned relate to legal restrictions, ethical, professional and social. The familiar situations were seized with the following measures: Consultation with applicable law; Information request various entities that oversee the areas covered; definition of anonymity in the query the database with profiles of students; Application for authorization and communication systems will, Direction of the grouping and presentation of the draft to the Council of

Teaching Group; Consultation with various stakeholders within the education sector. In this context data were collected through interviews with various actors directly linked to the Community Education, Director, Psychologist and other Teachers Group.

All these measures do not cover all the issues raised, nor eliminate the possibility of issues that impede the implementation of Progress Monitoring System, however this method of action-research has the advantage of refocusing the investigation in the case of a situation these occur, do not fully prevented the ongoing project.

WORK PROPOSAL

To research and implementing a prototype, this has involved consulting a wide range of sources of information: Ministry of Education, National Commission for Data Protection; ASSOFT - Portuguese Association of Software; legislation on data protection legislation and specific Students. We also consulted other bodies in the educational process (Director of the Grouping, Teacher, Psychologist in the Department of Psychology and Guidance, Sector Unions and Companies that supply software to the Clipboard) Interviews with Director of the Grouping, Teacher, Psychologist and Psychology Service Orientation which led to a working basis that underpins the model.

The fact that the Progress Monitoring System is not just another information system raises some preliminary questions. The modeling system should be divided into two parts: First stage of defining the system requirements must answer the following questions: What is the period of assessment to be analyzed? In which disciplines are the subject of implementation? The extraction, transformation and load (ETL) processes from the Program Student Management to the data warehousing (DW) support for the Progress Monitoring System? Implementation Phase of the system.

These phases should be divided by steps not necessarily sequential. Each phase includes not only the software involved, but all the accompanying administrative teaching method of the action.

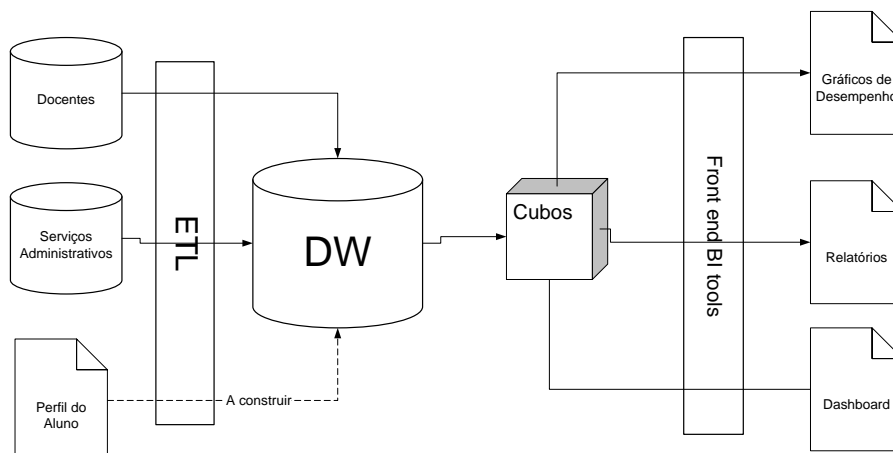

Figure 3: Architecture

Thus are defined the following steps:

Creation of DW - identification of sources of information with the results of students who completed secondary education as defined assessment period. This process needs to fetch data or automatically with an API (Application Programming Interface) and through the process that ETL all the grades of students who completed secondary education in the analysis. Thus the DW will have the following facts and dimensions indicated in the following figure, representing a multi-dimensional star model:

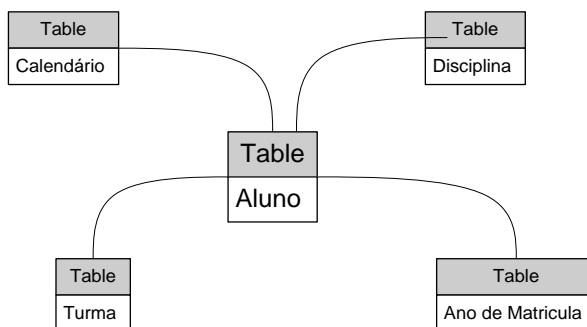

Figure 4: Fact Table / Dimension

In the implementation phase that DW should be loaded every period in each academic year, where a group of students to cycle to school under review, so that the DW reflects not only the latest changes in education policy, but also socioeconomic.

Set goals of students. This is one of the front-end of the DW, data marts that use the notes to match the student will be built functions to calculate the odds of getting marks on the basis of the profile created in the background Key Performance Indicators (KPI´s). Dashboard should be created which should indicate the chances of note and note minimum order. The calculation of these notes should be discussed between the parties involved. A proposal may be the minimum score is the median score of students who had the same starting note, the note target the note immediately above.

As for the pedagogical model following the process we have the following steps: Meeting of the Psychology Department and Orientation with the student - at this stage the Department of Psychology and Guidance collects all information it deems relevant to establish the starting point that is the note to be introduced as an indicator for DW. The Psychological Service and Guidance introduces the data in the Progress Monitoring System. At this point is assigned a tutor for the Student. The role of the tutor is of paramount importance because it will be the link between the system and the Student, whose function is to move information between Student Guardian Service, Psychology and Guidance, Class Director and Student Teachers. To allow for a good development work each Tutor must have no more than five students, the Department of Psychology and Guidance meets with the Student, Career and assessor- this meeting is agreed between all the targets set, encounters along the process among all stakeholders and the student with the tutor and the Department of Psychology and Guidance. Alerts are also quantified; Encounters with the Student Psychological Service and Guidance and Tutor – should set the schedule, which the working method to implement; alert type to implement – Manual or Auto – Manual rests with the Psychological Service and Guidance the Tutor, auto export is required for academic term management program for students of the register of Student Progress; extraordinary meeting whenever there is a warning –Developing a Plan of cognitive improvement.

Information to be recorded in the Register of Student Progress: Student Data; Initial Goals, Outcomes, Measures Implemented: Plans, Meetings, and Contacts.

The implementation model of the system as shown in Figure 3, with regard to the aspect of computer are as follows: Using the architecture DW (Kimball *et al*., 2008), initially the data recorded by the Teachers and Administrative Services Program Management curriculum Students will be pooled resulting in data warehouse. This process of extract, transform and load information at this stage groups the data by student, maintaining the anonymity of the same. DW will be implemented on a system of hubs that allows the extraction of data indicating the goals of the students. The information will be available in reports, charts and Dashboard's performance. In the second phase will create an application that allows the insertion of the goals of the students and monitor the progress of comparative results. At this stage the method of access must be controlled through the use of login and password information and constraining features of DW.

CONCLUSION

The Progress Monitoring System is more than a computer application, is a global model that aims to promote the educational success of students through the involvement of human, educational, technical and administrative. The Progress Monitoring System appreciates the merits and stimulates excellence, promoting and instilling motivation in the student blaming him for his educational success. This paper identified a few systems in the United Kingdom, where the system is already used for several years.

For an implementation in the Portuguese system, several organizations were consulted in view of the ethical and legal issues in the development of a prototype. Thus, we propose DW architecture, in order to take advantage of existing information sources in a pilot school. Through the ETL process will load a DW from which will be defined data marts for analysis and application of calculation formulas that allow the definition of the objectives pursued with the PMS. For the front-end we will provide dashboard presenting with the results obtained. In summary, the intended work focuses on developing a model close to the business intelligence business model.

310 - Professional Hierarchy, Vocation and Higher Education

Maria Vargas Hustana

Universidade Federal Fluminense – UFF, Brazil
hustana@gbl.com.br

Abstract: Considering the salary advantages and the increase of social prestige earned by high school graduates, maybe we could understand the expansion of enrollments in the last decade as an expression of society's democratization. However, actual implementation of a process of democratization in higher education involves other requirements, such as greater independence between the social background of those included in the system and their choice of careers. This is because although the higher education certificates represent social and economic distinction, between them there is great variability in relation to their social and economic returns in a hierarchy of professions. This is our research focus, taking into consideration the various challenges the process of expansion of education is facing nowadays. Its accessibility would be expressing a greater freedom of choice of careers? Taking the Brazilian case historically has been crystallized that the choice of a career has little relationship to the notion of "vocation", but the social conditions that shaped the choice. The definition for a university course could be described, primarily as a result of social constraints experienced by the student. Thus, we fail to provide youth the experience of vocational carrying out and certainly wasted talents that never came to be known and recognized. So we are interested in knowing, given the current process of expansion of higher education: in Brazil, how this situation has behaved? To answer that question, we propose an investigation of some undergraduate courses position in relation to the socioeconomic profile of the graduates in a time series, using socioeconomic data from national students from six courses, selected according to their degree of social status: three high prestige and three low prestige. In Brazil, are considered highly prestigious, among others, careers in Medicine, Law and Engineering. To these careers are opposed, for example, careers in teaching like Literature, Mathematics and Biology. We will investigate: 1 - What is the graduates' socioeconomic profile of those courses? 2 – In a time series, there are perceptible changes in these profiles? 3 - What policies can be designed in order to promote the democratization of access and permanence to the different careers? The objective is to evaluate the effectiveness of policies implemented in recent years towards the democratization of higher education according to the hierarchy problem of careers. It is also our objective in an international forum, to compare the findings for Brazil with the situation in other countries that are living a expansion process. We believe that these policies should be analyzed to discuss if we are facing a simulacrum of democratizing higher education, strengthening social positions at a time when, by contrast, social inequality may be being decreased. After all, we're thinking about the future, which should not be stuck in the past but taking with him valuable lessons to avoid history repeating itself as farce

Keywords: Professional hierarchy, Higher education, Social mobility

INTRODUCTION

In Brazil, the title "doctor"[141] incorporates several elements of distinction, based on the constitution of Brazilian history, on salary structure or on particular aspects of our social structure. As an object of desire and reverence, education explains between 30% and 50% of salary inequality in Brazil. It affects the poor distribution of wealth for two reasons: the marked educational inequality of the workforce, and the high rate of return to education, measured by the salary increase from an additional year of study (Psacharopoulos & Patrinos, 2004).

In relation to this point, a survey conducted in 71 countries ranked our country ninth in the greatest rewards for schooling. This return rate has been decreasing in all education levels since 1976, except for higher education, where it increased, on average, from 14.7% to 18.7% per year of study.

That forecast is worldly confirmed by the 2007 OECD Annual Report on Education (Portal, 2007). The document emphasizes that the increased proportion of people with higher education did not represent a reduction in salary, as they earn at least 25% more than high-school graduates in all OECD countries. Moreover, it shows that the unemployment rate of university graduates is seven percentage points inferior to

---

[141] Contrary to the rule under which the title "doctor" is used just for those who received the doctorate, in Brazil it extends to professions and social layers.

that of students who finished just the second year of high school, and five points inferior to that of high-school graduates. We cannot conclude those with a university degree carry out functions that are within their competences. However, the report confirms that the advantages of their position were not reduced because of higher education massification.

There is a peculiarity about university in Brazilian society: in a study on higher education expansion, Prates (2006) investigates the effects of secondary and tertiary education upon the socio-economic status of individuals in the National Household Sample Surveys (PNAD) of 1973, 1982, 1988, and 1996. Regarding the effects of tertiary education, contrary to what happens with secondary education, he concluded the following:

Not even the access to higher education minimizes the effect of parents' socio-economic status upon one's socio-economic status. Conversely, the possession of a degree certification increases the influence of parents' status over the definition of one's status in the occupational structure. Undoubtedly, according to these data, Brazilian society still not only did not break the effect of the status system upon the occupational status of individuals, but also reinforces the effects of this system upon the occupational status for the segment of the population with higher education (Prates, 2006, p. 18).

The same author (Prates, 2006, p. 15) finds that "the networks of social relations in Brazil are strongly linked to status heritage, and work as a kind of social capital that favors acquisition of the destination status". One of the typically meritocratic and most visible channels of social mobility in any contemporary society is higher education. Surprisingly, in Brazil, it is a factor that reinforces the most oligarchic and stratified face of society, even nowadays, breaking the effect of merit upon occupational mobility.

Stimulated by these conditions, in the mid 1990s, Brazilian university students amounted 5 million[142], an amazing increase in comparison to previous figures.
Source: MEC/INEP 2003 Higher Education Census
Graph 1: Evolution of the number of enrollments in higher education – 1980-2003 (in thousands)

This phenomenon owes to a movement for raising the status of education. Its inflection point is the promulgation of the 1988 Constitution. Article 208 subsection V establishes that the State's duties with education will be met through guaranteed access to higher levels of education, research and art creation, according to each person's capacity.

Considering salary advantages and the increased social prestige of higher education graduates, we may understand the increased number of enrollments in the last decade as an expression of society democratization.

However, for the actual democratization of post-secondary instruction, other requirements must be met. For instance: a greater independence between the social origin of those included in the system and career choice. That is because although higher education titles represent social and economic distinction, they vary

---

[142] They are 5,115,896 enrollments in on-campus courses, according to the 2009 Census of Higher Education. Available at: www.inep.gov.br. Access on March 11, 2011.

considerably as to social and economic returns, according to a career hierarchy. This hierarchy expresses, in the Brazilian reality, one of the most persistent and inflexible marks of inequality. Thus, if access to higher education could help attain social mobility and recognition, the levels of attainment would vary strongly according to the chosen career. On the other hand, we should discuss whether career is actually chosen or socio-economically imposed.

CAREER AND VOCATION OR CAREER AND SOCIOE-CONOMIC LEVEL?

Martins (2000) highlights the unequal character of higher education in Brazilian society: more than in other countries, strong elitist traits persist. Elitization, in the beginning, was identified with the reduced number of institutions and vacancies. However, the system evolved due to social dynamics, and the population gained increased access to more advanced educational opportunities. That slowly introduced new mechanisms of social discrimination and distinction, especially those related to: public approach versus private approach, university versus isolated institutions, elite education versus mass education, and courses traditionally dominated by socially privileged layers versus courses that absorb a socially heterogeneous public.

As regards the last one, associated with career hierarchy, several studies (Setton, 2002, Schwartzman, 1998; Queiroz, 2004) suggest a career typology in Brazil. The first study considers volume and type of capital found among students of several careers (Setton, 2002). The second classifies types of careers: traditional, modern and recent (Schwartzman, 1998). The third associates the ratio candidate/vacancy at university entrance examinations with labor market supplies (Queiroz, 2004). It is important to highlight that apart from the selected criterion of the hierarchical system, we find, at high education level, the so-called "imperial professions": Medicine, Law and Engineering. And at high school level, careers related to Teaching.

Our survey was designed within this scenario, taking into consideration the several challenges the process of education expansion presently goes through. Might wider access to higher education be expressing a freest career choice, thus stimulating a larger democratization process that encompasses: a) a concomitant vocational expression, and b) a projection of social mobility arising from the chosen career?

The Brazilian panorama

In Brazil, the choice of a career historically little related to "vocation", but to their determining social conditions. The decision on a university course could be described as a result of social restrictions experienced by the student. Thus, we fail to provide young people with the experience of vocational fulfillment, and, undoubtedly, we wasted talents that never came to be known and acknowledged.

About this, at the end of the 1990s, Schwartzman (1998, p. 15) warned:

> Choosing a career in Brazil nowadays has little to do with "vocations" and simple personal preferences, and much to do with personal and social conditions that determine that choice. No government policy on Brazilian higher education may be adopted without considering the implications of this fact.

Actually, beginning with university entrance examinations, which will select those with excellent performance, our country displays a previous degree of selectivity, observed in the heavier concentration of high-income candidates in socially prestigious courses. By contrast, lower-middle class competitors prefer courses of lower social prestige, in which they obtain a vacancy by delivering an average performance. One of these studies (Braga, Peixoto & Bogutchi, 2000) examined 10 years of university entrance tests at UFMG, verifying the following trend: even having obtained a grade high enough to enter a competitive course, if the candidates' socio-economic status were unfavorable, they were enrolled in a less competitive course. When the socio-economic condition was favorable, candidates did not avoid those courses, even getting poor results. The study concludes that "few candidates challenge the non-written hierarchy of courses and careers" (Braga, Peixoto & Bogutchi, 2000, p.21).

It is interesting to know how this situation has behaved in the current process of higher education expansion in Brazil. With this in mind, we propose an investigation about the position of some graduation courses. They will be examined in the socio-economic profile of graduating students on a time series, using national socio-economic data of students from six courses, selected according to the degree of social prestige: three highly prestigious and three little prestigious courses.

This option is due to the desired attention intended for both vocation and social mobility, admitting they will only be observed in the case of a student's greater socio-economic independence from the chosen career. In Brazil, Medicine, Law and Engineering are considered highly prestigious. They oppose to teaching careers, such as Language and Literature, Biology, and Mathematics. These have been the careers selected for the

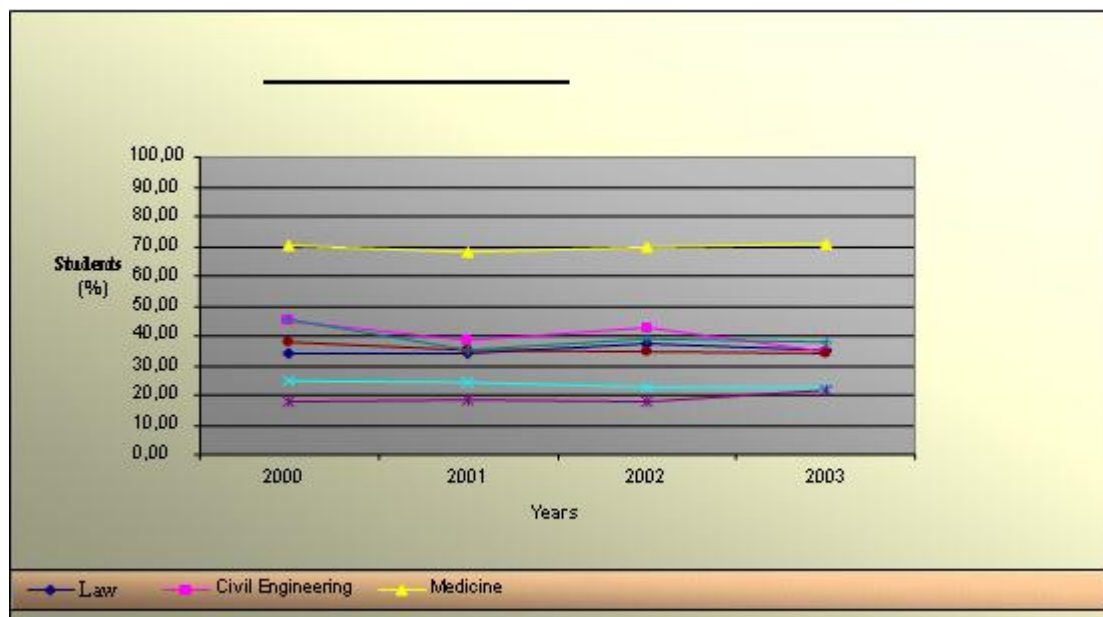
study, considering the fact that they reflect the three great knowledge areas. We will investigate: 1) the socioeconomic profile of those who finish these courses; 2) in a time series, whether changes in these profiles are perceived; 3) which policies may be thought of to favor the democratization of access and permanence at the different careers.

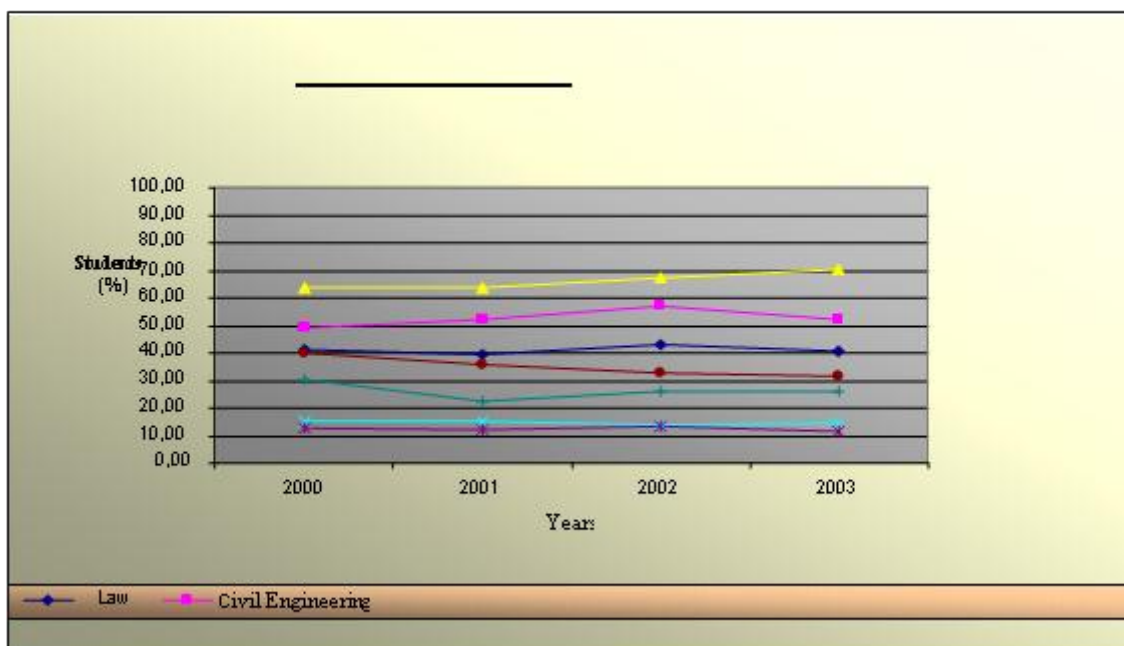
This work is aimed at assessing the efficacy of policies adopted in the last years to make higher education more democratic in relation to career hierarchy. It is also aimed at, in an international forum, comparing the findings for the Brazilian case with the situation in other countries that are experiencing an expansion process.

THE SURVEY

In order to conduct this study, we made use of micro data from the "Provão"[143] (a test for undergraduate students, which evaluates higher education in Brazil) between 2000 and 2003 – when the six selected careers participated in the exam, providing a sociologically coherent data bank. The time series was not enlarged because in 2004 the system to evaluate higher education changed, with the conduction of another exam4[144]. The "Provão" was taken by all undergraduates, together with a socio-economic questionnaire.

Concerning socio-economic variables, we used the socio-economic questionnaire of the "Provão". From it we detached some indicators that literature considers advantageous in the schooling process: color, parents' titles, income, occupation status, high-school of origin, and marital status (Foracchi, 1997, Martins, 2006, Schwartzman, 2000). The analysis of these indicators' behavior in each career then started to guide the study. We evaluated the situation of the selected careers amongst themselves and in comparison to all the others included in the "Provão" during those years. We called the group of the other careers "General"[145]. Here we present two of those variables in a graph: the student's occupational status and their parents' titles.





Source: *Micro data from the "Provão" INEP*
Graph 2: Graduating students who took the "Provão" and do not work, by course – 2000-2003

---

[143] 3Taken from 1996 to 2003 by all students at the end of graduation. Each year the process included more careers.

[144] The National Exam of Students' Performance (ENADE). The methodology is another. In order to have a four-year series, as the bank of the "Provão" provided, 12 years of ENADE would be necessary, since each course is evaluated each three years.

[145] In 2000, the category "General" comprised the following courses: Management, Agronomy, Biology, Social Communication, Law, Economics, Engineering, Physics, Language and Literature, Mathematics, Medicine, Veterinary Medicine, Dentistry, Psychology, Chemistry. In 2001, all those and also Pharmacy and Pedagogy. In 2002, Architecture, Accountancy, Nursing and History were added. In 2003, all the previous and Speech and Language Pathology, and Geography.

Source: Micro data from the "Provão" INEP
   Graph 3: Graduating students who took the "Provão" and whose father had a higher education degree, by course – 2000-2003

One may immediately notice an opposition between two separate groups: on the one side, the courses related to the teaching area (Biology, Language and Literature, and Mathematics); on the other, the most prestigious careers. Between both groups, there is the "General" line. The graduates of the three first courses are socially unfavored in comparison to all the others. Although we have illustrated this situation with the variables *work* and *parents' school level*, it is repeated with the others: in comparison to all the examined careers, in the teaching careers there are **fewer** students who are white, single, come from private secondary schools (more prestigious than public ones), and have high family income.

Later we examined the indicators' behavior, over the time series, in each of the selected careers. A pattern of stability was observed in all indicators, suggesting no socio-economic profile alterations in the courses. It is important to highlight that the studied years correspond to a moment of higher education expansion, with a more substantial number of enrollments, what could have changed undergraduates' socio-economic profile in the courses.

These empirical national results are based on studies undertaken in the same period or later, using large-scale data or not. For example, Beltrão and Teixeira (2005) disclosed, from census data between 1960 and 2000, a persistent correlation between color and course:

> What we may infer from the Brazilian census data is that the insertion of different color groups in university careers somehow reflects the order of participation by sex: in general, more masculine careers have smaller participation of black and mixed-race people; more feminine careers have larger participation of these groups (…). Some careers are exceptions to this rule, both among the more masculine and among the more feminine. Among the more feminine, the greatest relative insertion of black and mixed-race people occurs in Nursing, Geography and History. Among the more masculine, this greater insertion occurs in Theology and the military careers. It is interesting to notice that neither the careers fit the productive chain, but the market of symbolic goods. Geography and History are careers devoted to teaching, which, therefore, follow the same logic of the market of symbolic goods, with the additional advantage of having a steady clientele – students – as opposed to professions whose clientele need to be built (Beltrão & Teixeira, 2005, p. 175).

In the investigation "Women's trajectory in Brazilian education: 1996-2003", gender is the variable that relates to career option:

> Although gender frontiers have been moved, they still remain. It is true that some territories previously defined as masculine – among them, formal education, especially higher education – were occupied by a growing number of women. Even so, there is a territory very well marked out for women in professions that, being considered feminine, are undistinguished. It is in these professions that most women have searched higher education (Trajetória, 2006, p. 87).

Bastos' (2004) considerations follow the same path, in a study about social mobility among undergraduates of Law, Medicine, Social Sciences and Physics of the Federal University of Rio de Janeiro (UFRJ). Students from less favored social layers tend to prefer professions that bring more immediate economic advantages and are safer options. Nevertheless, this kind of need undermines their expectations regarding the most competitive careers, in which it would be impossible to invest without spending time and money – both scarce for them. The result is, predictably, quite the opposite of the intended, as they end up choosing less competitive and thus less profitable careers. "In other words, they are less prone to run risks; this eventually makes an upward social mobility difficult" (Bastos, 2004, p. 46).

Reports about the ENADE 2006 show that Teaching Training Courses present the highest proportion of black and low-income students, as opposed to Engineering and courses of the health area, also assessed in that year. These presented the lowest amounts of poor and non-white students[146].

> The highest proportion of black and poor students in teaching training courses, and the small presence of them in the areas of medicine and engineering have a strong relation to the degree of difficulty to enter the courses, and eventually affect future income. Medicine and Engineering, where the candidate/vacancy ratio is almost always higher than that of teacher formation, are also the courses to provide the highest financial returns.

Finally, the survey "Black youngsters and public university: context and challenges" (Araújo and Silva, 2007), with students of Pedagogy at the University of São Paulo (USP), for example, revealed that course was not the first option for any of the interviewees: their decision was made exclusively because of the minimum passing score. A student of Teacher Training, questioned about her motivation to choose the course, answered that "her decision was influenced by the fact that competition was less tough in exams for teacher formation than for areas like Medicine or Law" (Góis, 2007, p. C4).

As anyone can see, we are facing a recurrent and persistent circumstance in the social and educational Brazilian structure.

THE FUTURE BEING DELINEATED: "EXCLUDED FROM THE INSIDE"?

In a systematic way, Brazilian tertiary education has been perpetuating social patterns. Discussing the construction of citizenship at a public space with strong hierarchy in social relations as Brazil, Ângela Paiva (Paiva, 2006) considers higher education one of the most effective mechanisms to reproduce social inequality and control: "social reproduction was kept thank to a strong control of access to higher education, emphasizing and repeating our pattern of social inequality".

Data brought evidence that the highly prestigious courses are still territory of the elites. Improving access to them presupposes the adoption of compensation policies. Public universities have shyly taken positive actions, still with no major impacts. Socially less prestigious courses have been the object of major government efforts.

The expansion goal is pursued, based on programs like the Reuni, Prouni and EaD[147], (which have effectively increased the number of enrollments in socially unprestigious courses at public universities) or permitting most scholarships of Prouni and EaD courses to follow the same path. At the same time, the

---

[146] 6Mixed-race, black, yellow and Indigenous.

[147] Program to Support Plans of Restructuring and Expansion of Federal Universities (REUNI), Decree 6096/2007. It proposes the gradual increase of the average rate of conclusion in on-campus courses to 90%, and of the ratio between on-campus undergraduate students per teacher to 18. This Plan is aimed at reducing the rate of school dropping, occupying unfilled vacancies and increasing the number of vacancies, especially for the evening courses. Program University for Everyone (PROUNI), Law 11096/2005. Grants full or partial scholarships in private universities. The student who is granted a partial scholarship may have his part financed by FIES. As compensation, the institutions that adhere to the program are offered some taxes exemption. Distance Education (EaD): especially offered in courses of human and social areas, particularly, teacher education programs.

expansion of the higher education system towards unprestigious courses, without despising them, will not provide the necessary social mobility for a higher education coherent with either the objective of decreased social inequality, or with the total recovery of vocation as the basis for career choice.

Obviously, socioeconomic condition remains as the major determining factor of career option. We understand that the current process of higher education expansion has been reproducing the phenomenon of the "excluded from the inside", which Bourdieu (2002) described in relation to the French situation in the 1950s and 1960s. In this case, we would be before a fake democratization of higher education, reinforcing social positions in a moment when social inequalities should have been decreasing.

The Brazilian government has adopted incentive measures for the choice of teaching careers, our main concern, promising, in several official documents, to run a crusade for enhancing the status of teaching. We highlight one of these programs, the Institutional Program of Scholarships for Teaching Initiation (PIBID). It aims at reducing dropping out of these careers, granting scholarships to stimulate teaching. It serves students from Teacher Education Courses in Physics, Chemistry, Biology, Mathematics, Language and Literature, Pedagogy, and Art Education at federal universities, with the government's promise of gradually enlarging its scope. For students of private universities, the government offers the possibility of paying off their fees by working as teachers at public elementary schools.

Such measures are palliative, delayed and exert limited impact upon enabling the paths of vocation, social mobility and teaching to converge, more independently from social origin. More daring and consistent policies must be structured as to effectively change this static scene in which higher education functions, above all, as an instrument for reproducing social positions, making many give up their dreams of vocation and ascent. After all, thinking about the future, we must not be attached to the past, but learn from it, preventing history to repeat itself as a farce.

Take the case of Portugal, with labor laws that address the needs and specific rights of working students. Apart from all the educational policies formulated by the Brazilian government, perhaps this is a situation not yet faced: the need to combine study and work of a great contingent of students. Could this Portuguese experience contribute to effectively improve Brazilian students' conditions to attend higher education?

316 - Freshmen University Students in Latin America: What Young Students at Universidad Nacional De Córdoba Know, Do And Think About ICT

Joel Armando[1], Marcela Pacheco[2], Federico Ferrero[3] and Jessica Arévalo[4]

Facultad de Filosofía y Humanidades, Universidad de Córdoba, Argentina
[1]joel@ffyh.unc.edu.ar, [2] marcela@ffyh.unc.edu.ar, [3]fedeferrero@gmail.com, [4] jessiarevalo.s@gmail.com

Abstract: The paper briefly reviews literature around the "digital native" category as well as a summary of the ongoing debate regarding it, followed by a presentation of the results of a survey of freshmen students at UNC's School of Philosophy and Humanities.

The survey's results cast doubts upon the "digital natives" vs. "digital immigrants" categories that impregnate many an educator's and politician's discourse: they show that freshmen at a Latin American university (UNC) don't quite fit the image of the hyper-connected, network-dwelling, multimedia-producing youths who engage in political activities through virtual communities.

On the other hand, it suggests useful categories to better describe and inquire young people's actual on-line practices, as well as their cultural and ethical valuations, which may help us reflect upon the University's role in transmitting knowledge that is useful for the effective inclusion of students in current and future modes of citizenship and participation.

Keywords: University, ICT, youth, on-line practices

INTRODUCTION

This report is part of the two-year project "Teaching at the University for the Knowledge Society: ICT's role in the curriculum design processes," carried out by RED UNISIC148.

One of the project's main objectives was to understand how technologies become knowledge that needs to be taught, how they are incorporated into university curricula, in which character, at which curricular decision-making level their inclusion is promoted, how these prescriptions are enacted. Our approach focused on technologies not just as tools for teaching, but also as undergraduate subject matter linked to current transformations in knowledge production and distribution modes.

Among the second-year objectives of the project were: to analyze the role of Information and Communications Technologies (ICT) in university curriculum from the student's perspective, to develop a debate around the "digital native" concept taking into account different aspects such as age, social and cultural background, and the differences in access to ICT in each of the participating university's contexts, and to elaborate re-usable research tools for these different contexts (questionnaires-interviews). This report revolves around the partial results achieved at Universidad Nacional de Córdoba, Argentina (UNC) pertaining the debate on the concept of "digital natives".

Universidad Nacional de Córdoba (UNC) is a macro-university (Didriksson, 2002), with over 100,000 students and about 8,500 teaching staff. It is the hub of scientific activity in the region, with 98 research centres, over 1000 projects carried out by nearly 3,000 researchers, over 250 scholarships and 50 PhD programs. A 2006 study (Gewerc, 2007) found that UNC is "loosely-coupled:" faculties were weakly articulated, with structures and functions that often overlap. Gewerc and her team found access to ICT for teachers and students to be poor, with little or no training in education technology, while existing technology remained under-exploited. Although teaching staff claimed to use digital resources significantly, most usage was text-based rather than multimedia or interactive (Edelstein, Pacheco, Armando, Giordanengo & Uanini, 2009).

UNC is organized into 12 faculties dedicated to teaching, research and community activities in different subject areas. Face-to-face teaching prevails within the organizational structure of the *cathedra*: a hierarchical team with divisions of tasks and responsibilities linked to teaching.

---

148   Composed of Universidad de Santiago de Compostela, Spain (USC), Universidad Nacional de Córdoba, Argentina (UNC), Universidad de San Francisco Xavier, Bolivia (USFX), Universidad Joan Misael Saracho, Bolivia (UJMS) and Universidad de la Frontera, Chile (UFRO), research coordinated by Dr. Adriana Gewerc and funded by AECID. http://unisic.usc.es/

The present work's structure is divided in three sections: in the first one, we summarize some current debates around the concept of "digital natives", making explicit the theoretical and methodological decisions underpinning our study.

The second section describes the results of a survey of all freshmen students of UNC's School of Humanities and Philosophy, taken through a comprehensive on-line questionnaire.

The third section introduces our conclusions and suggests further discussion topics, taking into account information from interviews taken at later stages of the project.

The "Digital Native" concept under the spotlight of youth's practices: Theoretical approach and researched aspects

A fair share of literature on youth and new technologies emphasizes their character as "digital natives." Different authors gave different labels for this category: "digital natives" (Prensky, 2001), "Net generation" (Tapscott, 1998) and "millenials" (Howe and Strauss, 2003) are but a few of the proposed names for this stipulated generation of people who are intuitively familiar with digital media and rely on ICT for their everyday activities. They are described as living lives immersed in technology, "surrounded by and using computers, video games, digital music players, video cams, cell phones, and all the other toys and tools of the digital age" (Prensky, 2001, p.1).

Proponents of the concept contrast young people's apparently inborn ability to deal with digital media to their teacher's difficulties and resistance to change, and put an emphasis on informal learning, as opposed to classroom learning, which they portray as inadequate for modern society.

Different authors have criticized these claims, as well as the consequences of taking them at face value when making decisions about the inclusion of ICT in education.

Bennett et al., (2008) have made a point of questioning the theoretical soundness of those premises, as well as the lack of empirical evidence supporting them. Surveys aimed at gauging the knowledges, attitudes and beliefs of young people about technology, such as those conducted by Livingstone and Bober (2004) and Selwyn (2006), contradict the image depicted by the proponents of the concept.

In (Dussel y Quevedo, 2010), the authors warned about the political and pedagogical consequences of uncritically accepting the "digital native" discourse, and the risks educators face when adopting this position, because they may see themselves as impotent witnesses of transformations beyond their control:

> "In other words, the notion of «digital natives» usually puts initiative, dynamism, and even responsibility for the dynamics generated by new media in the hands of the youth, and tends to exculpate and brush aside what adults can do to promote richer, more relevant and more challenging uses of these technologies […] We believe that the debate about new technologies and their impact on the education system should originate on the responsibility of public policies, education systems and adults for the uses and practices that arise around them." (Dussel y Quevedo, 2010: 12, original in Spanish)

The debate over digital natives thus revolves around on two key issues: (1) whether a distinct generation of "digital natives" indeed exists; and (2) whether education must fundamentally change to meet the needs of these "digital natives" (Bennett, 2008).

One way to question the first of these claims is through further research on youth and their relationship with digital technologies, seeking better and more comprehensive information on the practices they develop, the knowledge they build as well as their values and attitudes on the subject.

Towards this goal, we build upon descriptions of the cultural consumption of young people in Argentina and Latin America (Toer, Martínez Sameck, Chávez Molina, 2003; Godoy Rodriguez, 2009), as well as research on how students experience the university (Carli, 2007; 2008).

Godoy Rodríguez (2009) applied the ICT Skills Index to university students in Barina (Venezuela), and presented his results in a case study. ICTSI is a standardized European instrument, aimed at measuring the student's self-reported experience levels in the use if digital technology. A comparison of his results with those obtained in Europe allows him to assert that Barinese university students' instrumental ICT skills are on par with those of European students. His findings provide empirical support to the idea that the "Digital Divide" gets narrower when students begin their university studies. This suggests that whatever divide exists between Barina's students and those of developed countries, it's more likely to be an educational divide than one related to access to digital technology.

Inspiration for our questionnaires was provided by a comparative study performed by Toer and his team, who surveyed University of Buenos Aires freshmen's cultural consumption. They designed a questionnaire

that, while custom-made to fit the cultural environment of the subjects, remained comparable to a similar study the University of California at Los Angeles (UCLA) has been conducting on US higher education freshmen for the last three decades.

Many authors point out that a growing body of research on youth culture has developed recently, but it only ventures in inquiries about cultural groups that participate in practices that are notable for being spectacular or exotic (Buckingham, 2008; Herring, 2008) either in their mode of execution or in their results. This tendency to ignore the more banal uses of technology, and to dedicate studies to the exceptional cases seems to call for a change of perspective in research. The challenge consists in building an outlook on the experiences of youth and university from the point of view of everyday life and apparently trivial minutiae.

In the context of University education, this is an analytical approach that doesn't ask about the organization in itself, but rather starts questioning about the student's own experience. According to Carli (2007), this enables us to desecrate our homogeneous view of students, and to reconstruct the stage of university experiences. This perspective postulates that institutions that ignore certain cultural codes and practices of the young people who study in them need to re-characterize their student populations.

We also take into account studies that do focus on the most innovative new media practices young people engage in, with the aim of characterizing what the "new" element in them is. In this sense, the definition of "New Literacies" proposed by Lankshear and Knobel is of particular interest.

> "Socially recognized ways of generating, communicating and negotiating meaningful content through the medium of encoded texts within contexts of participation in Discourses." (Lankshear and Knobel, 2007:2)

The authors speak of socially recognized ways in the sense of "practices," as tasks oriented towards social goals. Practices always include the interplay between technologies, knowledge and skills. Such a literacy is a set of organized practices that make use of a system of symbols together with technology to produce and negotiate meaningful content and to participate in social environments.

The distinctive feature of the "new literacies" approach is, then, the desire to better understand how people codify, receive and negotiate meaning in the current technological context. According to Coiro et al. (2008), new technologies for information and communication and new visions for their use require us to bring new potentials to literacy tasks that take place within these technologies. New literacies are central to full civic, economic and personal participation in a world community.

With regards to the knowledge that pertains to these new literacies, Lankshear and Knobel (2008) propose digital remix as a new writing mode that is characteristic of young people. The idea of remix includes the issue of appropriation and mixing of existing cultural contents, the multi-modality of the mixed matter and the collective character of these constructions.

Another feature of these new literacies would be participatory culture. Jenkins (2009) postulates affiliations, expressions (the production of new creative forms), collaborative problem solving and circulations (shaping the flow of media, such as podcasting and blogging) as forms of participatory culture.

Authors such as Ito (2010) have researched into how new media are being taken up by youth practices and agendas, and how these practices change the dynamics of youth-adult negotiations over literacy, learning, and authoritative knowledge.

In the same line of work, James (2009) focuses on the investigation of the ethical contours of the new digital media and the creation of interventions to promote ethical thinking and, ideally, conduct.

These precedents allowed us to structure our study around the concept of experience (Carli, 2008), investigating the everyday practices of all students, while at the same time recognizing the wide range of uses, conceptions and practices of young people with new media, even the most extraordinary. Our survey was conceived to consider five main dimensions: 1) socio-demographical variables, 2) chosen career (reason for the selection, expectations towards the future), 3) cultural consumption and extra-curricular activities, 4) access to information and communication technologies and 5) values and attitudes in connection with ICT.

The socio-demographical dimension include variable such as gender, age, marital status, education of the parents, work activities (if present) and school/academic provenance of the student. Analyzing this dimension requires, at the least, considering the recent transformations in Argentina's social fabric, and its impact in higher education institutions. This transformation, which has taken place in our country since the '90s has extended to a new structure in the social composition of universities. In this framework, sociologists have mentioned the descent of middle class and the emergence of the "new poor" as those who didn't originate in the lower classes, but rather from the impoverished middle class. Universities are no strangers to

this circumstance, and have become heterogeneous spaces shared by students from different social origins (lower, middle and impoverished middle class, as well as middle and higher classes).

Questions about the chosen career and expectations around it are open-ended, and attempt to broadly investigate how students picture the study of their chosen subject matter, its associated profession and its job perspectives.

For the access and use dimension, the questionnaire attempts to gather information about the use of ICT, taking into account the possibility of material access as well as the practices that students develop with them. Questions try to assess the availability of computers at home, the modality and location of Internet access, the degree of autonomy when browsing the web, and the frequency of use of specific devices.

In order to evaluate the features of cultural and technological consumption and the preeminence of consumption vs. production of cultural objects through digital media, we ask about the frequency with which the subject performs specific activities or uses specific technologies. The answers to these questions also provide hints about the level of proficiency of the subject, through the evaluation of the skills required for each activity. We also inquire into the most popular kinds of language and textual modalities, both in learning and extra-curricular activities involving ICT.

On the issue of learning modes and values associated with the use of digital media and Internet, the questionnaire asks about how students evaluate technology and on-line activities, and how they learned to engage in them. Questions approach issues such as whether they received formal education on the subject, whether they are aware of Free Software, perceptions about how on-line activities affect democracy, privacy, relations to other people, etc., following James' (2009) argument that five key ethical issues need to be addressed: new media identity, privacy, ownership and authorship, credibility and participation.

What young students at Universidad Nacional de Córdoba's School of Philosophy and Humanities know, do and think about ICT

The questionnaire described in the previous section was answered by all 1,126 freshman students of the School of Philosophy, except for those of the Art department, which enjoys a special status and a fair amount of independence due to the fact that it's in the process of becoming its own School. The data was correlated with those obtained in 2009 through a survey on "Quality of Life and Health Status of UNC's Student Body", which was answered by students from different academic units, and serves as a baseline against which to compare our specific group of students.

Female, young and mostly single

The survey shows that the majority of School of Philosophy and Humanities freshmen at UNC are female (62.5%), between 18 and 23 years (53,3%) and single. The School has nine departments: History, Philosophy, Literature, Anthropology, Education, Library Science, Geography, Archival Science and Arts. The present study encompasses all of them except for Arts, and the demographics vary strongly from department to department: while Philosophy and Literature students are mainly young, relatively well-to-do and have a stronger male presence, Archival Studies attracts more working-class women and has a larger age average.

Half the students at UNC have parents with complete tertiary or universitary studies, which is consistent with our results: 78.6% of parents of our students have complete secondary studies, while 49.6% have completed graduate studies at a higher education institution. At the lower end of the spectrum, our students show a more favorable situation (7.6% of parents with none or just primary instruction) than the university average (14%). When we concentrate in the mothers, we find that 83.7% of them has graduated from secondary school, while 35.9% have obtained an university degree.

For the most part, physical access to technology isn't a problem

In general terms, School of Philosophy freshmen's physical access to technological resources is slightly above the average for UNC students: 86.9% of them have access to a computer at home (UNC: 84.5%). A more detailed analysis, however, reveals a more complex scenario: only 62.6% have a computer for personal use (as opposed to sharing it with the rest of the family), and just 27% has a mobile computer. Although 78.5% of students has access to the Internet from home, 29% of them do connect through narrow-band dialup lines.

Both access to hardware and connectivity correlate mainly with career choice and social provenance, we found no significant correlation with age or sex, aside from a very light trend for older students to have better access.

Diverse uses: mainly for learning purposes

Frequency analysis of access to particular devices as well as participation in certain activities on the Internet reveals that looking up information, enjoying music, communicating with peers and doing homework are the most common uses of digital technology. Participating in communities, gaming, image processing and video editing are only marginally present. This suggests that learning-related are more prevalent than entertainment uses or other uses not related to school.

Looking at the frequency of "very often/often" answers, we can rank computer uses as summarized in Table 1 and Table 2.

Breaking up these uses along the lines of career choice, age, and sex reveal variations that deserve a more detailed analysis than can be done within the scope of this work. The most frequent uses, however, do not show any significant variations among age groups: career choice once again seems to be more closely correlated to frequency of each use than age. Sex, on the other hand, shows significant variation only on specific activities, such as gaming.

Diverse uses: prevalence of alphabetic over multimodal text

Table 2: Frequent uses of computers

	Very often / Often	Seldom / Never	Missing	Total
Send/receive e-mail	82,70%	13,30%	4,00%	100,00%
Study, do homework	81,80%	14,20%	4,00%	100,00%
Write	73,40%	22,60%	4,00%	100,00%
Listen to music	68,40%	27,60%	4,00%	100,00%
Keep in touch with friends	48,80%	47,20%	4,00%	100,00%
Look up bibliographical information	59,50%	36,50%	4,00%	100,00%
Download music, movies, files	50,40%	45,60%	4,00%	100,00%
Prepare presentations	35,40%	60,60%	4,00%	100,00%
Record numerical data / perform calculations	27,00%	69,00%	4,00%	100,00%
Edit images and video	31,40%	64,60%	4,00%	100,00%
Edit music	16,90%	79,10%	4,00%	100,00%
Draw or design	10,00%	86,00%	4,00%	100,00%

The data from the tables 3 and 4 show clearly that activities based on alphabetic text, such as writing, looking up information, doing homework, sending and receiving e-mail are more frequent than those that involve image, sound, and video editing or data processing, which are among the tasks the majority of freshmen students never tackle. The analysis of these frequencies points at a predominance of alphabetically-coded textual representations (essentially, reading written text). This suggests that photo and video remix activities such as those described in Lankshear and Knobel (2008) are not widespread.

Table 3: Frequent uses of the Internet

	Very often / Often	Seldom / Never	Missing	Total
Look up information	90,80%	5,30%	3,90%	100,00%
Download music, movies, files	82,10%	12,50%	5,40%	100,00%
Visit specific sites	77,30%	18,80%	3,90%	100,00%
Study, do homework	57,00%	37,60%	5,40%	100,00%
Search for useful works for school	56,80%	37,90%	5,30%	100,00%
Read newspapers/magazines	51,00%	43,60%	5,40%	100,00%
Chat	43,30%	51,30%	5,40%	100,00%
Social networking	35,00%	59,60%	5,40%	100,00%
Publish photos, video, music	23,70%	70,90%	5,40%	100,00%
Participate in fora	13,20%	81,40%	5,40%	100,00%
Gaming	11,50%	83,10%	5,40%	100,00%

Among non-alphabetic texts, watching videos and listening to streaming music are fairly popular activities which remain confined to the extracurricular space, since Humanities education still privileges written text as its preferred vehicle of analysis and study.

Diverse uses: prevalence of consumption over production
The data also challenge the notion that young people are predominantly producers of works for the net: participation in fora, keeping a blog or publishing images, music or videos are very rare, in contrast to consumption activities such as looking up information, downloading media, reading magazines and newspapers. Here again we can see a predominance of consumption activities over production, and the virtual absence of any activities that can be conceived as participative culture (Jenkins, 2009).

Optimism about Internet's social role, on the possibilities for learning, the value of information and the risks of addiction
The questionnaire asked participants to rate the degree to which they agreed or disagreed with a number of propositions such as "Internet promotes social equality" or "Internet is a threat to my privacy."

Table 4: Beliefs about the Internet

	Agree / Strongly agree	Disagree / Strongly disagree	Missing	Total
Broadens possibilities for communications	91,00%	3,60%	5,40%	100,00%
Promotes learning	91,00%	3,60%	5,40%	100,00%
Provides participatory tools	84,00%	10,60%	5,40%	100,00%
Is essential to modern life	78,40%	16,20%	5,40%	100,00%
Is useful for meeting people	77,00%	17,60%	5,40%	100,00%
Creates addiction and dependence	72,60%	22,00%	5,40%	100,00%
Offers a lot of low-quality information	71,30%	23,30%	5,40%	100,00%
Makes learning better	66,50%	28,10%	5,40%	100,00%
Is a threat to my privacy	58,00%	36,60%	5,40%	100,00%
Broaden social inequalities	52,90%	41,70%	5,40%	100,00%
Promotes social equality	51,30%	43,30%	5,40%	100,00%

These results show optimism with regards to the net's potential for communication, social participation and meeting people, as well as more concern about addiction and dependence than about erosion of privacy. The positive perception of the Internet as tool for learning stands in contrast with the widespread view that the quality of information found there is not on par with its quantity.

Self-taught, better knowledge of technical than of political issues
The majority of students (59%) taught themselves the basic skills needed to surf the net, and 60.7% of respondents don't think they need help to use the Internet for their studies.
These answers can be put in contrast with those related with the issue of Free Sofwtare: 59.8% of respondents don't know what Free Software is. Some comments by students on this issue focus on technical explanations without mentioning the social value and political position of the Free Software movement.

CONCLUSIONS
This study was built upon the concept of experience (Carli, 2008), inquiring about the everyday practices of all our freshman students while recognnizing the wide range of uses, conceptions and practices of young people, including the most extraordinary.
In order to be able to describe our students in terms of socio-demographical characteristics as well as with respect to access and use of ICT, we conducted a survey that recognized them as primarily female, young, single, second-generation higher education graduates. Most don't work, and many of them have selected the career as a second choice after a previous university experience, although these indicators vary strongly among careers. They have access to computers and the Internet, on which they primarily do e-mail and search for information. They are optimistic about the value of the net in individual uses and learning, but skeptical of its contribution to a more egalitarian social order.

These young people's practices are divided between learning-related and extra-curricular activities. Alphabetically-coded text dominates both kinds of activities, although non-alphabetic texts are slightly more frequent in extra-curricular activities than in curricular ones.

In the same vein, a comparison between consumption- and production-related activities shows a strong bias towards the former. These two last realizations allow us to point out that even young people with better physical access to information technology than the university average are far from the proposed characterization of the "digital native".

On the other hand, interviews conducted for later stages of the project indicate that it is often teachers who demand the use of certain technologies from students and who include them in on-line participation modes.

These results, which are beyond the scope of this article, show that students are surprised to be confronted, in their very first year of study, with a learning proposal that includes teaching technologies and demands of them to develop certain skills in order to partake in the process.

Our results are consistent with the idea, stated by Bennet et al. (2008), that the debate about "digital natives", rather than being empirically and theoretically informed, can be likened to an academic form of a 'moral panic.'

> The time has come for a considered and disinterested examination of the assumptions underpinning claims about digital natives such that researchable issues can be identified and dispassionately investigated. This is not to say that young people are not engaged and interested in technology and that technology might not support effective learning. It is to call for considered and rigorous investigation that includes the perspectives of young people and their teachers, and genuinely seeks to understand the situation before proclaiming the need for widespread change. (Bennett et al., 2008, p.784)

Our data, and that of fellow researchers doing empirical studies, suggest that young people's relationship with technology is not as uniform as the "digital native" characterization implies. Their skills, knowledges and practices vary strongly, and we found no evidence of them preferring any radically new way of learning, nor of holding views or attitudes that make them fundamentally different for the rest of the population. Our data suggests that practices do not vary strongly with age, and that while access is an important element of acquiring the necessary skills, it is not unevenly distributed among age groups.

If anything, the results from our survey show that the strongest influence in the practices and uses of technology is exerted not by sex or the year of birth, but by the individual's own interests as expressed in their career choice. This variation probably merits further study, to gain knowledge that may help us meet students with expectations that their match reality better than a blanket assumption that they will be able to intuitively figure out technological artifacts.

320 - Academic Dishonesty- Understanding How Undergraduate Students Think and Act

Carla Freire[1,] Sandra Marisa Miranda[2]

[1]University of Minho, School of Economics and Management Department of Management, Braga, Portugal, [2]Lisbon Polytechnic Institute, School of Communication and Media Studies, Lisbon - Portugal
cfreire@eeg.uminho.pt, smiranda@escs.ipl.pt

Abstract: The purpose of this study is to explore and understand the justifications given by students to the existence of dishonest behavior and understand the extent to which the justifications given might influence denouncing and cheating behavior. 1277 undergraduate students of two Portuguese Public Universities were surveyed about their own cheating behavior, their propensity to denounce and the "neutralizing attitudes". Results indicated that the likelihood of copying is greater when the purpose is "helping a friend", "when the courses are more difficult", "to get higher marks/grades", and because "peers accept and tend to see copying practices as normal". As predicted, "neutralizing attitudes" was positively correlated with one's own cheating behavior and negatively correlated with reporting. Results support the notion that context emerges as a very important influence in the decision to cheat. The environment-peer pressure and the normalized attitudes towards academic dishonesty are the main influences on the propensity to cheat.

Key Words: Academic dishonesty; Cheating; Plagiarism

INTRODUCTION

The wealth and global competitiveness of a country stands in the quality of its education system. Academic dishonesty undermines the quality of education and it´s against the education system´s major aims - to create responsible and respectful citizens. The normalization of academic dishonest behaviors may have an influence on those who will be the future decision makers of the country. Thus, students' beliefs and practices about academic integrity are likely to influence individual and business ethics values.

The interest in ethical behavior in general and misconduct in particular has increased in the recent years mainly due to the publication of ethical scandals in the academia but also in the industry context. Academic misconduct is not new – indeed it has been extensively studied in the literature (McCabe & Trevino 1993, McCabe & Trevino, 1997, McCabe et al., 2002). The incidence of the phenomenon, and the indications that is increasing over time, seems to be justified by the fact that cheating is "normal" among students (Rettinger & Kramer, 2009).

However, the problem of cheating at schools seems to be more serious now. The most recent studies show that the number of student cheating has increased rapidly during the last decades (Drake, 1941; Hetherington & Feldman, 1964; Baird, 1980; Jendreck, 1989; Smyth & Davis, 2004; McCabe, 2005), their attitude toward cheating have changed, as well as ways they cheat. The question is what has led to such expansion of academic dishonesty? According to some researchers, the most influencing factor was the fast technological progress, and the development and popularization of the Internet (Lathrop & Foss**,** 2000), which have enabled students to cheat with ease in ways that were hard to imagine several years ago.

Understanding how students think actually and what are the main influences in their decision to commit an academic dishonest behavior may allow higher education institutions to discourage such behavior, as ensuring the academic integrity at different education levels.

Knowing the valid reasons considered by students to cheating behavior help to rationalize some behaviors. Dishonest behavior may include "submitting a paper done by someone else, "not collaborating in a team assignment ","copying on tests/exams from someone else", "using unapproved materials on a test/exam", "allowing someone to copy in a test", "plagiarizing a paper – whole or partially, using the internet", "writing a paper for another student". Denouncing an incident of cheating or plagiarism includes denouncing "a friend," "a stranger", "if anonymity were guaranteed" and "if there was a code of honor". Those who copy tend to consider cheating as an acceptable behavior and tend to describe it as a cause of external factors.

In this sense, the purpose of this study is to understand the justifications given by students to the existence of dishonest behavior and understand the extent to which the justifications given can influence denouncing and copying behavior.

LITERATURE REVIEW

The idea that dishonest behavior is common among undergraduate students has been well documented in the literature (McCabe & Trevino 1993, McCabe & Trevino, 1997, McCabe et al., 2002) and has focused on its causes and effects (Kisamore et al., 2007). The interest in ethical behavior in general and academic dishonesty in particular has increased in recent years mainly as a result of publicizing of scandals in academia and business as well.

Academic dishonesty is not a new phenomenon, indeed it has been extensively studied in the academic context and empirical evidence indicates that is changing and increasing in recent years. Drake noted that 23% of the students copied in 1941, Hetherington and Feldman pointed out to a rate of 64% in 1964 and Baird, in 1980, recorded an incidence of 76%, in 1989 Jendreck estimated a rate of around 40/60%. And in 2004, Smyth and Davis pointed out to a rate of 74%. The study by McCabe (2005) also recorded high rates of cheating, of around 71%., demonstrating that the phenomenon is more serious in business schools.

The literature on cheating in the U.S. can be divided in two separate approaches: the individual differences approach that relates the individual variables with the incidence of dishonest behavior, and the contextual approach that analyze the importance of situational or contextual factors as predictors of cheating.

Whitley (1998) cataloged the individual differences into five dimensions: demographic characteristics, attitudes toward cheating, personality variables, and situational factors. McCabe and Trevino (1997) found that few studies on academic integrity had been conducted in more than one campus and had examined individual and contextual factors (Davis et al., 1992; McCabe et al., 2002; McCabe & Trevino, 1997). The studies that have focused on the individual differences approach have used variables such as sex, age, academic achievement, level of parental education and participation in extra-curricular activities.

Recent studies suggest that male students copy more than female, worse academic results students copy more than students with good results, the lowest parents educational level is associated with cheating, and students involved in extra-curricular activities such as fraternities /sororities and intercollegiate athletics devote less effort to study and more to dishonest behavior (McCabe & Trevino, 1997).

On the other hand, contextual factors that have been mentioned as an influence on cheating include honor codes, students' perceptions of peers' behavior, students' perceptions of faculty's academic integrity policies, students´ perceptions of the effectiveness of these policies, students´ perceptions of the likelihood of being reported, and students' perceptions of the severity of penalties .

How students think and act

Understanding how students think and what affects their decision to have a dishonest behavior may allow academic institutions to reduce its incidence. To discourage such conduct, academic institutions can ensure more honest behavior in different educational levels. Those who copy can find justifications for the fraud they committed and thereby mitigate the cognitive dissonance of their behavior. Literature indicates that neutralizing attitudes are often correlated with cheating (Haines et al., 1986; Pulvers & Diekhoff, 1999). Neutralizing attitudes are not considered a sufficient cause for cheating but could help to rationalize certain behaviors. According to Murdock and Stephens (2007), who copies tend to consider their behavior acceptable when they can describe it as a cause of external factors. Watching others to copy, knowing that others copy regularly and that others do not take the matter too seriously may facilitate the neutralization of those attitudes.

The study of Davis et al. (1992) helps to understand an inconsistency between students´ beliefs and actual behavior. They found that around 90% of students affirmed that copying it is incorrect and that teachers should be concerned if students copied and 76% of those students admitted they copied in the university.

The research of Smyth and Davis (2004) also reflects an inconsistency between attitudes and behavior, where although 92% of students consider the behavior of cheating unethical and 45% indicates that it is a socially acceptable behavior. In this regard, some studies have suggested that while students recognize the seriousness of academic dishonest behaviors many students learn that copying is a common behavior in universities despite the prohibition of political institutions (McCabe et al. 2002; Smyth & Davis 2004).

The model of academic dishonesty proposed by McCabe and Trevino (1993) takes as its premise the concept of social justice in that it suggests that the perception of peers' behavior is the most influential variables of the dishonest conduct of students (McCabe et al., 2002), ie, the observation of fraudulent conduct has an effect of normative support for cheating and social acceptance of such conduct.

Researchers argue that when students believe that others copy and when they believe that their schools do nothing to discourage such behavior this argument may be used to justify their own behavior (McCabe, 1993, McCabe et al., 1999). Another justification can be given based on goal orientation theory which argues that students may be learning-oriented or performance-oriented (Anderman et al. 1998; Dweck 1986;

Rettinger et al. 2005). A performance-motivated student is more motivated to copy, while learning-motivated students are less able to copy (Jordan 2001, Newstead et al. 1996).

METHOD

Participants

1277 undergraduate students of two Portuguese Public Universities were surveyed about their own behavioral intentions to cheat, their propensity to report cheating and their justifications or "neutralizing attitudes". The sample is composed by 64,4% female students and 34,8% male students. Their ages ranged from 17 to 61 with a mean of 20, 45 (SD= 3,82). 30,7% were first year students, 32,3% second year, 32,4% third year, 2,3% fourth year students and, finally, only 1,3% were fifth year students. 9,5% were working students. Entrance Grade Point Average (GPA) was 158,4 (SD=14,23) and course average was 137,4 (SD= 16,26).

Measures

Behavioral intention to cheat – The behavioral intentions to cheat is a 7-item scale (α=0.76) assessing the likelihood of considering misconduct. A five likert scale was considered (1-never; 2- very unlikely; 3- somewhat unlikely; 4 – somewhat likely; 5 – very likely). The list includes items adapted from an on-line survey administered by Millersville University and Kisamore et al. (2007) investigation.

Some examples are "turning in work done by someone else as one´s own", copying from someone else during a test", "using unapproved materials to complete an assignment", "not collaborating in a team assignment", "allowing someone to copy in a test", "plagiarizing a paper, whole or partially, using the internet", "writing a paper for another student".

Reporting Cheating – The reporting cheating scale is a four-item scale (α=0.82) designed to assess how likely students are to report a friend, a stranger, "if anonymity were guaranteed" and "if there was an honor code", whom they observe engaging in academic misconduct. A five likert scale was considered (1-never; 2- very unlikely; 3- somewhat unlikely; 4 – somewhat likely; 5 – Very likely).

Neutralizing attitudes – The neutralizing attitudes scale measure the justifications given by students. Students were asked about the reasons why some of them copy or allow others to copy. The neutralizing scale is a 13-item scale (α=0.73) describing academic misconduct as a cause of external factors. Some examples are " to help a friend", "due to lack of time", "because they feel pressured by colleagues", "because there is not much control by teachers", "because the punishments are less severe", "laziness", "because they want high grades", "when the subjects are very complex", "because colleagues accept and consider such behavior normal", "because does not exist a code of honor", "because everyone copy", "because they are dishonest", "because the assessment is based on memorization". Students were requested to indicate the extent of their agreement with each of the statements using a scale ranging from 5 "strongly agree" to 1 "strongly disagrees".

Demographic Variables: The participants were also asked to report their age, gender (males coded as 1, females coded as 2), Grade point average (GPA) (course average), schooling year (1st, 2nd, 3th, 4th and 5th) and students status (1 - ordinary and 2 - working student).

RESULTS

Approximately 60% of the participants affirmed never to the likelihood of turning in work done by someone else as one's own, and 40% admitted such misconduct. Not collaborating in a team assignment is considered by 31,2% of participants. Only 25,8% of students answer that they have never considered the possibility of copying on a test or exam for someone else. 74,2% admitted to have considered the possibility of copying at least once in a written assessment exercises.

The likelihood of participants' consideration of engaging in academic misconduct reveal that allowing someone to copy in a test is well tolerated (13,4% say never and 86,6% admitted such behavior).

64% of students admitted the possibility of using unauthorized material in the evaluation exercises at least once, and 36% never admitted so. 57,8% said that they have never plagiarized a paper, whole or partially, using the internet and 42,2% admitted they have considered such misconduct. Finally, 37.7% of respondents admitted the possibility of writing a paper for another student.

83,7% of students do not consider the possibility of denouncing a friend while, in the case of a stranger, 62,6% has admitted to do it. If there were anonymity guarantee allow 43,1% of students would consider reporting a fraudulent behavior. If there was a code of honor, 53,6% of students would consider the possibility of reporting an academic misconduct.

Helping a friend is the most appealed explanation given by students to copying or allowing to copy (87,6% agree and strongly agree). 55,3% of students agree or strongly agree that they copy because colleagues accept this behavior as normal.

Other justifications presented are related to the teaching and learning process. 72,2% of students believe that the fraudulent conduct occurs when the subjects are more difficult, or to obtain higher marks/grades (68% agree or strongly agree) or when the assessment exercise is based on memorization (53,9% of students agree or strongly agree). 56,7% of the students points out the lack of time to study as the main reason that justifies the cheating behavior.

For students, cheating is not synonymous of dishonest conduct. Approximately, 50% of respondents disagreed that the act of copying suggests students´ dishonesty. Students demonstrate lack of information to respond to the question about the honor code existence (38.6% refers not having an opinion). Students reject the justification that everyone copies and that they feel pressured by peers (70% of both disagree).

In sum, the likelihood of copying is greater when "helping a friend", or "when the subjects are more difficult", or "to get higher marks/grades", and because "peers accept and tend to see copying practices as normal".

In order to test the dimensionality of "neutralizing attitudes" a Principal Components Analysis with Varimax orthogonal rotation was performed (table 1) according to the *eigenvalue* method (Kim and Mueller, 1978), verifying the confirmation of the Kaiser-Mayer-Olkin (KMO) test and of the Bartlett (*sign.*< 0.001) sphericity test. For each factor, items with loadings above 0.45 (Howell, 1992) are selected. In order to assess the internal consistence of the factors, the *Cronbach alpha*'s value is considered.

Table 1: Factor Analysis with Varimax Rotation of Neutralizing attitudes

Itens	Loadings		
	Indvidual focus	Learning process focus	Environment-peer pressure
"laziness"	**,765**	,213	
"because they are dishonest	**,686**	-,238	,111
"because the punishments are less severe",	**,679**	-,184	,324
"because does not exist a code of honor",	,485	-,119	,481
", "because there is not much control by teachers"	,453	-,116	,444
"when the subjects are very complex",		**,747**	,108
"because they want high grades"	,436	**,627**	
"due to lack of time"	-,228	**,622**	,176
" to help a friend"	-,132	**,550**	,185
"because everyone copy",		,118	**,711**
"because colleagues accept and consider such behavior normal"	,271	,115	**,617**
"Because the assessment is based on memorization".		,240	**,543**
"because they feel pressured by colleagues"	,114	,232	,348

Three factors emerged from the factor analysis. The first factor groups 5 items (with loadings above 0.45) and shows a *Cronbach*'s α of 0.727. This factor refers to an individual focus. The second emerging factor groups 4 items and presents a *Cronbach*'s α of 0.709. The third factor emerged was named environment-peer pressure. One item of this factor was withdrawn, since it was found through the analysis of the internal consistency that it would cause for an increase in its internal consistency.

Correlation analyses were conducted. As shown in Table 2 a justification individual centered is negatively correlated with one's own cheating behavior (r=- 0.156, p<0.01) and positive correlated with reporting (r=0.147; p<0.01). A learning-process justification is positively correlated with one's own cheating behavior (r= 0.260, p<0.01) and negatively correlated with reporting (r=-0.116; p<0.01). An environment-peer pressure justification is positively correlated with one's own cheating behavior (r= 0.129, p<0.01).

Neutralizing attitudes are reasons regarded as valid in order to find justifications to their actions. The results indicate that students who admit reporting peer´s cheating behavior consider that behavior is due to laziness, dishonesty and because the punishments are not severe enough. Students who admit the possibility of one´s own cheating behavior justified it as a result of the learning-process, ie, when the subjects are complex, when

students want higher grades and as a result of lack of time available for study. A context based justification is given by students who have admitted to copy /plagiarize.

Table 2: Descriptive statistics and correlations among variables

Variables	1	2	3	4	5	6	7	8	9
1.Own cheating behavior	(0.76)								
2.Reporting	0.001	(0.82)							
3. Individual focus	-0.156**	0.147**							
4. Learning process focus	0.260**	-0.116**	0.000						
5.Environment-peer	0.129**	-0.037	0.000	0.000					
6.Gender	0.013	0.007	0.012	-0.015	0.033				
7. Age	-0.060*	0.081**	-0.002	-0.116	0.065*	-0.025			
8.Schooling year	-0.012	-0.023	-0.003	0.021	-0.013	0.623**	0.013

*p<0.05; **p<0.01

Note: Gender was coded 1= Male; 2= Female; Students' status was coded 1=ordinary; 2= working student

DISCUSSION AND CONCLUSIONS

The likelihood of participants' consideration of engaging in academic misconduct reveal that allowing someone to copy in a test is well tolerated. Results indicated also that majority of students admitted to have considered the possibility of copying at least once in a test/exam and using unauthorized material in the evaluation exercises. Otherwise, a minority admitted to have plagiarizing a paper, whole or partially, using the internet.

Results indicate that copying in a test or plagiarizing a paper even though they are both dishonest academic behaviors they are at the same time are different in terms of physical and psychological involvement. Privacy is the big difference between copying in a test than plagiarizing a paper. Copying in a test requires public exhibition. The others´ direct scrutiny may have a social desirability effect and in consequence an obedience to social norms. In this sense it can be expected that cheating on tests is more influenced by situational and contextual variables. Results indicate that copying in a test is excused by friendship and the normalization of the act. The students felt that their colleagues accept and consider cheating as normal. Although students understand that cheating is against rules, often look at colleagues and realize that copying is acceptable and can be "peer pressure" to copy (McCabe et al. 1999).

Plagiarism is usually a private activity that is more individual motivated than situational motivated (Rettinger & Kramer 2009). So it could be greater social condemned than cheating on tests. Results revealed that most students consider that copying in a test is more socially accepted. McCabe and Trevino´s model (1993) suggest that a cheating disapproval is associated with a decrease in such behavior. It will be therefore admitted that in contexts where this behavior is acceptable cheating has a higher incidence.

According to Pulvers and Diekhoff (1999) one of the aspects that neutralize cheating behavior is the belief that "everyone copy". In this study only a small part of the students consider that this is a valid justification for fraudulent behavior.

Murdock et al. (2007) concluded that a style of performance-oriented teaching can be considered a neutralization attitude. Results indicated that the likelihood of copying is greater "when the subjects are more difficult ", or "to get higher marks / grades".

Results indicated also that for students, cheating is not due to a really dishonest conduct. This attitude revealed that students tend to consider their behavior acceptable when they can describe it as a cause of external factors and do not ascribe this to justify a lack of integrity or intellectual dishonesty. Otherwise, knowing that others copy regularly and believe that others do not take the matter too seriously may facilitate the neutralization of those attitudes.

In sum, these results support that context emerges as a very important influence in the decision to cheat (more on cheating on a test). This paper concludes that the environment-peer pressure and the normalized attitudes towards academic dishonesty are the main influences on the propensity to cheat.

Neutralizing attitudes are reasons regarded as valid in order to find justifications to their actions. Who report a peer cheating behavior considers that behavior is due to laziness, dishonesty and a lack of punishment. A learning-based justification and a context based justification are given by students who have admitted to copy /plagiarize.

This study represents a step forward to understanding the "justifications" given by students to the academic misconduct; however a confirmatory factor analysis is essential. Taking into account the lack of studies on academic integrity, further research should explore the directions pointed out in this study. It would be pertinent to explore some academic integrity policies.

334 - Mathematics Intervention Programme as a Mediating Tool to Enhance Student Teachers' Learning and Teaching of Mathematics: an Activity Theory Approach

Subethra Pather

Faculty of Education and Social Science. Cape Peninsula University of Technology, Cape Town, South Africa
pathersu@cput.ac.za

Abstract: This study was prompted by concerns of mathematics teaching and learning in the South African education system. Contributory factors to this situation were the lack of competent mathematics teachers in the classroom and mathematically *at risk* students entering teacher education programmes. This paper reports on how a mathematics intervention programme (MIP), assisted in shaping *at risk* students' perceptions of their learning and teaching of mathematics. Activity Theory is used as a theoretical underpinning in examining student teachers' perceptions of their learning and teaching of mathematics in the MIP. Qualitative data was collected and analysed using interview transcripts, test scores, and written and graphical reflections of the student teachers experiences. The results confirm that the students' perceptions of their learning and teaching of mathematics had changed and concludes that the MIP had a positive effect on the students' with regard to improving their: attitudes; level of confidence in learning mathematics; teaching strategies and mathematics performance.

Keywords: Activity theory*, at risk* students learning and teaching of mathematics

INTRODUCTION

A serious challenge facing South African universities is to improve throughput rates of students. The Minister of Higher Education and training in South Africa, Blade Nzimande (2010), has appealed to South African universities that whilst access to universities must increase it must also be accompanied by increases in graduation and success rates at all levels of study.

Higher education institutions are thus not only faced with the everyday challenge of excellence in teaching and learning, but also have to engage in student support programmes for those who enter the tertiary institutions bearing scars of apartheid education.

Even though South Africa is now seventeen years into post-apartheid transformation, there is still a large number of students who graduate from high schools ill-prepared for higher education. This is due in part to resource constraints and unqualified or under-qualified teachers. As a result many students who enter higher education are *at risk*[149] of failing due to their poor grounding within the South African school system.

The ill-prepared first year university students, particularly in mathematics and science subjects, are of great concern to the academic fraternity (Surty, 2005). The lack of adequately qualified school teachers has been cited as one of the contributory factors in this regard (Asmal, 2002). According to Crouch and Perry (2003) the number of unqualified (lower than grade 12 certificate plus diploma or degree) teachers in the system is considered to be substantially high. Thus Higher Education Institutions (HEIs) which offer teacher education programmes have an important role to play in addressing this problem.

One of the unfortunate consequences of underqualified teachers is that many South African high school graduates enter teacher education programmes with a poor grasp of mathematical concepts and, in some cases, an associated dislike for the subject. Although these trainee student teachers are exposed to mathematics education at teacher training institutions, many of them graduate and return to the classroom, without having overcome their aversion for the subject (Setati, 2004). As a consequence they contribute to student indifference to the subject and the continuance of the vicious cycle.

Academics involved in mathematics education programmes at teacher education institutions have a responsibility to break this cycle. This requires a variety of interventions, especially at first year level, needs to be designed and implemented to support students. An important factor that needs to be taken into account, when devising intervention programmes for first year students, is their school-based learning experiences.

---

[149] In this study at risk is understood to be a student who risks academic failure because his or her skills, knowledge, motivation and academic abilities are significantly below that of a typical student (Maxwell, 1997).

According to Eaton & Kidd (2005) the experiences that these students have during their formative years in the classroom have shown to have a major impact on their behaviour as teachers. Parson (2004) highlighted that in the school system low achievements and repeated failure in mathematics often result in negative attitudes and lowered confidence which in turn lead to mathematics avoidance at tertiary level and increased risk of failure.

One approach to tackle poor performance in mathematics and an aversion of the vicious mathematics cycle would entail intervention strategies which have a positive influence on student teachers' perceptions of learning and teaching mathematics.

The case of one such intervention sets out the broad context in which the research problem of this study was located. Specifically the study investigated how a mathematics intervention programme, was able to shape the student teachers' perceptions of their learning and teaching of mathematics.

CASE STUDY: A MATHEMATICS INTERVENTION PROGRAMME AT A TEACHER EDUCATION INSTITUTION

In an attempt to address the concerns of poor mathematics performance and an aversion for the subject, the academics managing the B Ed programme within the Faculty of Education at a University of Technology in Cape Town implemented a mathematics intervention programme. Four important factors, specifically related to the B Ed, General Education and Training (GET: Grade R to 8) programme that underpinned the implementation of the MIP were as follows:

  i. Mathematics and Numeracy form a fundamental part of the Primary School Curriculum.
  ii. The incoming students' low level of preparation for the introductory mathematics course.
  iii. The rapid increase in student intake and the concomitant change in the diversity of students' academic backgrounds and profiles.
  iv. The high drop-out rate at first year level.

The design of the MIP targeted students who were *at risk* of failing the first year *Introduction to Mathematics* course. The MIP occurred in parallel sessions to the mainstream introductory class and took place twice a week for the full academic year. Each class was forty five minutes in duration. The total hours allocated was 36 hours for the year an additional 10 hours were allocated to accommodate a slower pace of teaching. This afforded the students the opportunity to ask questions and seek assistance. Fundamental to the programme was the small class size, averaging twelve students. The intervention class was optional and was taught by a qualified mathematics specialist.

THE RESEARCH QUESTION

What aspects of the Mathematics Intervention Programme shaped the student teachers' perceptions of their learning and teaching of mathematics?

This paper will focus on the following two sub-questions:

  How has the *MIP classroom environment* influenced the student teachers' perception of their learning and teaching of mathematics?

  How have the *teaching and learning strategies* (mediating tools) used in the MIP influenced their perceptions of their own learning and teaching of mathematics?

LITERATURE REVIEW

The literature reviewed for this study focused on perception studies, intervention programmes, learning and teaching strategies and Activity Theory (AT). Literature dealing with students' perceptions of learning and teaching mathematics included: Tchoshanov, Blake, Della-Pianna, Duval & Sanchez, 2001; Schuck, 1998; Holt-Reynolds, 1994 and Schoenfeld, 1994. Studies which reported on mathematics intervention programmes included Gervasoni, 2005; Doig, McCrea & Rowe, 2003 and Pearn & Merrifield, 1996. Constructivist theory of learning and teaching strategies associated with mathematics took into account the studies done by Cobb, 1994; Collins, Brown & Holum, 1991 and Vygotsky, 1978. Finally attention was given to AT, Engeström's (1987) which formed the central focus as a theoretical and analytical framework for this study. The following section explained AT in more detail so as to understand the context of the study.

Activity Theory (AT)

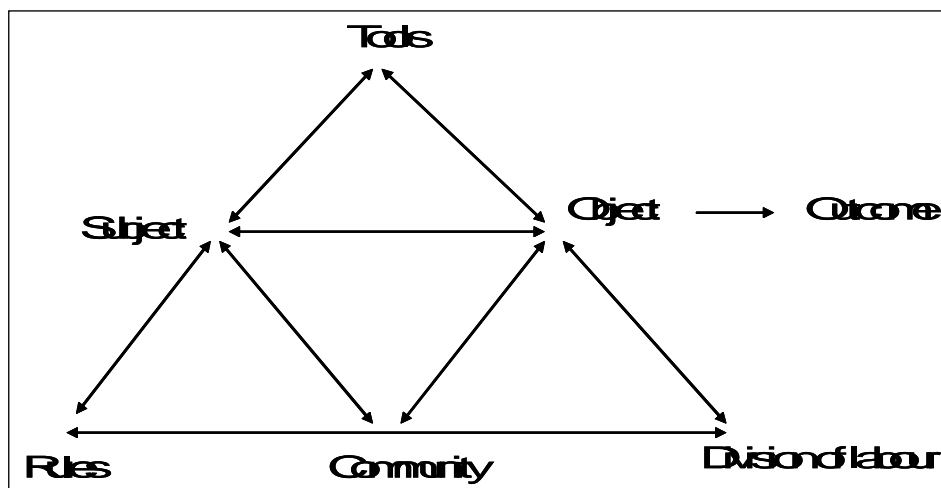
Activity Theory provided a framework for co-ordinating the constructivist and socio-cultural perspectives in mathematics learning. According to Cobb (1994) activity plays a crucial role in mathematics development and learning from both a constructivist and socio-cultural perspective in mathematics education. These are important perspectives in the research problem environment of this study and therefore AT provided a suitable *lens* through which the research objectives could be achieved. As stated by Hardman (2005) AT does not have predictive power and is best viewed as a heuristic device for identifying, examining and aiming to answer research questions related to human activity.


Figure 1: The basic triangular model of AT (Engeström 1987:78)

Activity Theory was derived originally from the work of Soviet cognitive psychologists, especially Vygotsky (1986) and Leont'ev (1978). The well known triangular model (Figure 1) of AT was developed by Engeström (1987, 2001). It has been widely used descriptively and analytically in many parts of the world. The model is composed of interacting components: ***subject, mediating artefacts or tools, object, division of labour, community and rules***. It portrays the inter-relationships between the subject, object, and mediating tools, set in the social context of rules, community, and division of labour.

According to Engeström (1987*)* the analysis is conducted from the point of view of the ***subject***, which could be an individual or group. This component forms the focus of the action. The subject uses mediated means or tools to reach the object. The ***object*** is the central issue to, or which the activity is directed and eventually leads to an outcome as a consequence of the activity. Kuutti (1996) asserts that a ***tool*** can be anything used in the transformation process, including both material tools and tools for thinking. Tools alter the activity and are in turn altered by the activity. Engeström (1987) intended that the ***rules*** component refer to the explicit and implicit regulations, norms and conventions that constrain actions and interactions within the activity system. It defines how subjects must fit into the community. The ***community*** for Engeström (1987) comprises multiple individuals and/or subgroups who share the same overall object and who construct themselves as distinct from other communities. The community component therefore includes the notion that an activity is carried out within a social and cultural context of the environment in which the subjects operate. The ***division of labour*** or *roles* describes how the object of the activity relates to the community. It refers to both the horizontal division of tasks between the members of the community and the vertical division of power and status (Engeström, 1987).

The unit of analysis in AT is the activity system. Russel (2002: 67) states that the activity system is a *flexible* unit of analysis (theoretical lens) which allows the researcher to train their *gaze* in different directions and with different levels of *magnification* to help the researcher answer the questions that *puzzle* them.

An important question that underpins the understanding of AT is *what is activity?* Cole and Engeström (1991) define an activity as a form of doing, which is intentional and directed towards the creation of a physical or mental object. This in turn leads to an outcome. Their model of activity highlights three mutual relationships involved in every activity:

- the relationship between the subject and the object of the activity, which is mediated by tools;
- the relationship between the subject and community, which is mediated by rules; and
- the relationship between object and community, which is mediated by the division of labour.

Cole and Engeström thus see relationships occurring between elements within the activity as crucial to transforming the object into an outcome.

An Overview and Critique of Activity Theory (AT)

Engeström's model of AT has been used as a research framework and a heuristic supporting innovation in a wide array of contexts including education, healthcare and human-computer interaction (Engeström, 1987, 1993 & 2000; Roth, 2004 and Thorne, 2007). According to Thorne AT does not separate understanding (research) from transformation (concrete action), it encourages engaged critical inquiry to enact positive interventions.

However, Roth (2004) argues that there are still many unsolved issues relating to AT. Work conducted by Daydov (1999), lists some of these problems as relating to the nature and role of transformation in activity systems, the relation of collective and individual activity, and the relation of AT to other theories of human conduct.

Other authors have been critical that there are several areas in which AT has still not been applied, For example, Hardman (2005) expresses a concern that while there are numerous examples of the application of AT in interventionist research to analyse a variety of contexts, there are few analyses dealing with the use of AT in exploratory studies at the level of the primary school classroom. She is further critical that though AT is used primarily as an interventionist tool, it struggles to track the emerging object of complex activity systems observationally.

One of the main critiques of AT is that it has been applied within diverse disciplinary settings. Therefore a researcher, who is unfamiliar with multi-disciplines, would find it a challenge to come to terms with the application of AT as it would require a review of studies in such a variety of contexts. On the other hand, the diversity of application of AT could also be viewed positively, in that this is demonstrative of its pliant nature and as such is easily adaptable. Roth and Lee (2007) for example refer to AT as being an accommodating framework, rather than a set of neat propositions. Indeed, this was found to be the case in considering if AT could be applied to this study. Additionally, as a sufficient number of relevant studies in education were identified in the literature surveyed, I believe there was a strong case to support primarily the use of AT as a theoretical underpinning for this study.

RESEARCH METHODOLOGY

The principal research strategy adopted was that of *case-study* research. An interpretivist approach and qualitative methodologies were deployed in this study.

Participants were purposefully selected from amongst 60 first year B Ed student teachers attending the MIP. Semi-structured interviews were then conducted amongst the twelve student teachers and the MIP lecturer between March and May 2007. Prepared interview schedules as well as picture cards [150] were used in the interview.

The interview transcripts formed the primary data source for analysis and provided the means to understand the change in mindsets of the subjects. This data was supplemented with students' test scores as well as illustrative and written reflections of their mathematics experiences that were captured during a separate exercise.

NVivo (a qualitative data analysis software tool) was used to facilitate the process of content analysis. This involved identifying, coding, categorising, classifying and labelling the primary patterns in the data, and then mapping these onto an expanded activity system, viz., an AT model.

The findings were based on analysing the subjects' perceptions of the MIP. These findings were presented within an AT framework and were viewed within the six components of Engeström's activity system.

---

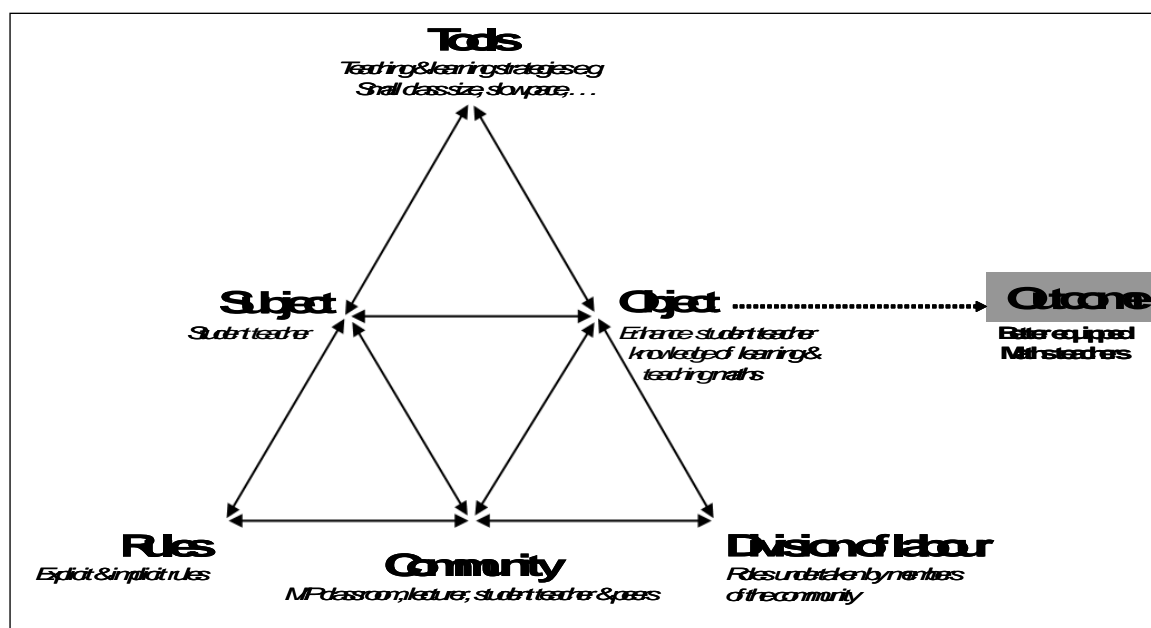
[150] During the interview subjects were given eight picture cards, as shown in Figure.3 (page 11), the subjects had to arrange these cards according to the aspect that made the most significant to the least significant contribution to their learning and teaching of mathematics whilst in the MIP.


Figure 2: Engeström's Activity System as applied to this study

For the purpose of this study (as defined by Cole and Engeström, 1991) the activity was defined as the student teachers' learning and teaching of mathematics within the MIP learning environment. The upper part of the triangle in Figure 2 (subject, object and mediated tools) was used to examine how the student teacher used the mediated tools to scaffold and build on their own understanding of learning and teaching of mathematics. The lower half of the triangle (rules, community and division of labour) was used to examine how the social environment within the MIP classroom influenced the student teachers' perceptions of learning and teaching mathematics.

Activity Theory thus facilitated a holistic interrogation of the student teachers' learning and teaching of mathematics within the social setting of the MIP classroom. In addition it magnified each component to be examined individually and with equal attention. This enabled me to explore the relationships between the six components of the AT system as they pertained to the research problem. This process produced both rich and sufficiently detailed findings in respect of the research questions and enhanced the quality of the study through ensuring the credibility, transferability and dependability of the findings.

RESEARCH FINDINGS

In answering the research question the findings in this paper are presented according to the following components of the activity system i.e. the subject (student teachers); the mediating tools (teaching and learning techniques); and the community (classroom environment, peers, lecturer). The activities within these areas were examined at both individual and social levels to determine whether the MIP influenced the student teachers' perceptions of their learning and teaching of mathematics (object).

The Subject: Student Teachers

The subjects' demographic information and excerpts from their interview considering their prior school-based mathematical learning experiences, provided an important background.

The following significant observations were identified about the subjects:

- The majority of the subjects in the study were students who returned to the university after an extended period of absence from formal learning. This meant that many of them were not familiar with the *Outcomes Based Education (OBE)*[151] approach to learning mathematics.
- The majority of the subjects did not have the basic mathematical grounding needed for the B Ed mathematics course.

---

151   OBE was implemented in 1998 into the South African education system as a curriculum reform intended to replace the old education system of content-based approach to primarily a learner-centred approach that included continuous assessment and outcomes-based education.

- More than half of the subjects were not English first language students. However when questioned about the impact of learning mathematics through the medium of English in the MIP they all indicated that the medium of instruction was not a debilitative factor to their learning of mathematics.
- Remarks with regards to the subjects' prior school-based mathematical learning experiences were indicative that they generally had a negative attitude and a fear of learning mathematics.

The foregoing provided a backdrop of the subjects' experiences and their particular needs in the learning environment of the MIP. The discussions of the findings that follow take into account this profile of the subjects.

Mediating Tools: Teaching and Learning Strategies
A wide variety of teaching and learning strategies were used as mediating tools by the MIP lecturer to improve the subjects' performance. No standardized teaching or learning model was used. However, all teaching strategies used are subsets of various theoretical teaching perspectives. For example modelling, scaffolding and coaching are associated with cognitive apprenticeship instructional model (Collins, Brown & Holum, 1991); group work, small class size and promoting student responsiveness is associated with collaborative learning (Vygotsky, 1978; Bruner, 1996); and learning and interacting with assistance from a more capable peer or lecturer is associated with Vygotsky's (1978) Zone of Proximal Development (ZPD).
The different teaching and learning strategies used were adopted specifically for the needs of the student teachers in the MIP class. The strategies were intended to achieve the following: reduce mathematics anxiety, build confidence, and improve performance and understanding of learning and teaching mathematics. The techniques used aimed at allowing the student teachers to complete tasks with minimum effort, frustration or anxiety and reach levels of performance that they had previously felt was unachievable.

Student Teachers' Perception of Learning and Teaching Strategies
The subjects were asked to identify what learning and teaching strategies were used in the MIP class. What emerged from the analysis was that some strategies that were used by the lecturer were not necessarily identified as learning or teaching strategy by the subjects.

Table1: Teaching & Learning Strategies identified by the students

	Teaching & Learning (T & L) strategies identified by subject (From most identified to least)
1	Small class size
2	Use/making of objects
3	Plenty of examples & repetition
4	Slower pace of work
5	Worksheets
6	Group work
7	Question & answer
8	Overhead projector
9	Homework
10	Board work

The analysis of the interviews suggested learning and teaching strategies that subjects were familiar with were not perceived as mediated tools. For example, very few of the subjects identified homework, board work, the use of the overhead projector and questions and answer techniques as teaching and learning tools. Strategies that were new to the subjects or had an impact on their learning of mathematics were perceived as mediated tools, for example, the use of worksheets, use/ making of objects, group work, plenty of examples and repetition.
A strategy that appeared to be very successful was the small class size. All the subjects interviewed acknowledged that the small class size was effective in their learning of mathematics. This is supported by Gillies (2006) who found that (i) students benefit academically and socially from small group learning; and (ii) students' and teachers' verbal behaviour in small groups was more caring, spontaneous, personal and positive as the teacher and students worked more closely.
Another strategy that was effective was the slower pace of lessons. Many of the subjects appreciated the relaxed pace in which the lessons were conducted and regarded this as beneficial to their own learning. From the small percentage that did not particularly approve of the slower pace of work, half of them used this time

to teach their peers and also work out additional examples. This advanced their teaching and learning of mathematics. However the remaining half expressed boredom and noted at times they felt tempted not to attend class. This underscores the importance of the learning environment being individualisedWith regards to the subjects' teaching of mathematics the data revealed the teaching and learning strategies that were identified to be most effective to the subjects' own understanding of mathematics (Table 1, number 2 to 6) were utilized when they taught mathematics during practice teaching. From the analyses it emerged that many of the subjects mirrored their MIP lecturer's techniques of teaching mathematics. This important observation was indicative of the transference of the learning in the MIP into the external school environment.

The Community: MIP Classroom Environment
The community comprised of the classroom environment, peers, subjects and lecturer. The findings in this section focus on the abovementioned components:

The Classroom Atmosphere
The group-style layout of the desks and chairs created adequate space for movement and interaction with peers and the lecturer. The subjects' responses to the classroom atmosphere were: the MIP class had a relaxed atmosphere; their work and comments in the class were valued, respected and accepted by the lecturer and peers: they also established the class to be a non-judgemental environment; they felt safer in the MIP class and this security encouraged and offered them a better scope to explore innovations and undertake a trial of a wider range of strategies in solving mathematical problems.

Peers in the MIP Classroom
The peers of the subjects facilitated the social interaction in the community. The subjects were involved in exploring, co-operating, sharing and reflecting with their peers. Such involvement brought about security, self confidence and a reduction in anxiety for many of the subjects.
The cooperative working environment in the MIP also allowed the subjects to take on roles such as observer, teacher and facilitator assisting their peers.

The Lecturer
The lecturer's prior teaching experience with *at risk* mathematics students and teachers and being au-fait with the MIP aims positively influenced the interactions in the MIP community. The analysis of the interview data with the subjects and lecturer showed that the lecturer was able to:
- demonstrate insight about teaching and learning strategies;
- reduce mathematics anxiety;
- enhance students' basic mathematical skills and confidence;
- provide a supportive and stimulating learning environment and
- encourage independent decision-making amongst groups or individuals.

The supportive role played by the peers and lecturer constructed an environment that was different from other learning communities outside the MIP environment. It was unique in the sense that the subjects were aware of each others' weak mathematics foundation, they felt they were all in the same 'boat' and needed to support and encourage each other.

Subjects' Perceptions of the MIP

Responses from the picture cards exercise (Figure 3) formed part of the evidence in reporting on the subjects overall perception of the MIP.

Figure 3: Analysis of 'sort cards' exercise

The following five observations were noted by the subjects from the picture cards:

- All acknowledged that the MIP had definitely improved their performance in mathematics. This was collaborated by their test and examination results.
- The majority felt collaborative learning was very effective. .
- A large percentage acknowledged an increase in their confidence and attitude towards learning mathematics and also a shift in their perception of learning mathematics.
- In contrast to the subjects' confidence and motivation to learn mathematics, their response show a lower confidence and attitude to teach the subject. The student teachers felt that they were not ready to teach mathematics even though their marks had improved.
- Finally, in response to the learning of mathematical concepts, a small percentage acknowledged a change in their learning style. The assumption here is that many subjects did not fully understand what was expected of them.

DISCUSSION OF FINDINGS

In answering the research question:

What aspects of the MIP shaped the student teachers' perceptions of their learning and teaching mathematics?

The findings indicated two important aspects of the MIP which promoted a positive outcome in respect of the way in which student teachers' perceived their learning and teaching of mathematics:

i.   classroom environment; and
ii. teaching and learning strategies used in the MIP.

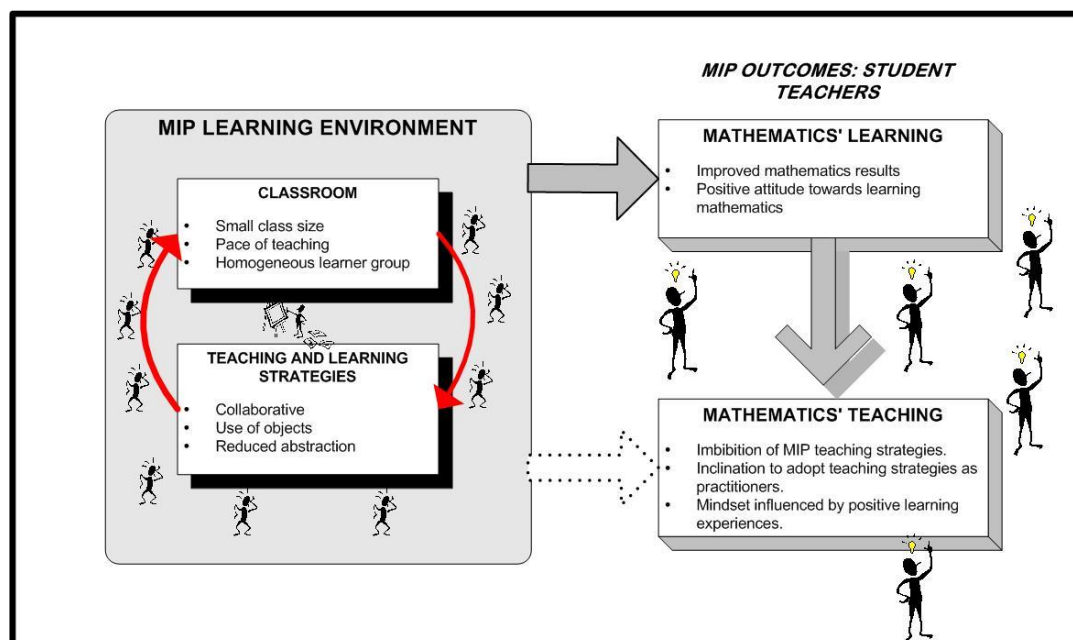
Importantly (i) and (ii) above were not mutually exclusive contributors to the positive outcomes. Rather it was the ongoing *interaction* between the elements of the classroom environment and specific (i.e. not all) teaching and learning strategies applied by the MIP lecturer, which jointly contributed to a change in perception amongst the subjects as reflected in Figure 4 below.


Figure 4: Overview of how the MIP influenced student teachers' learning & teaching of mathematics

MIP: Classroom Environment

A key theme which emerged through the analysis of the student teachers' interviews was the facilitating role of the MIP classroom environment, as shown in Figure 4. Aspects of this environment were emphasized by all interviewees. The small class size, the slower pace of learning and teaching and the homogeneous learner group collectively provided uniqueness to the environment.

Secondly, the findings also point to the university classroom environment as a crucial component in guiding students towards an interactive and constructivist approach in their learning activities. This enhanced a self-awareness of the student teachers' own cognitive abilities which they then applied to the tasks in the MIP.

A third finding highlighted the characteristics of the MIP learning environment as being relaxed, non-threatening and comfortable. This resulted in the students having an elevated sense of confidence to: seek help from the lecturer and peers; try out new ways of solving mathematical problems; and voice their opinions, debate and discuss mathematical issues with the lecturer and peers.

The sense of confidence gained by the student teachers helped them to realize their self-worth, as they felt valued and respected in the MIP learning environment. This in turn resulted in a positive attitude and improved confidence towards learning and teaching mathematics.

Learning and Teaching Strategies

The various learning and teaching strategies used in the MIP class, to scaffold and build on the student teachers' knowledge of learning and teaching mathematics, assisted the diverse group who had varied learning needs. This mediating tool played a critical role in fostering a change in the student teachers' perceptions of learning mathematics. The following teaching and learning strategies (see Figure 4) were identified as the major contributors to the student teachers' learning of mathematics:

- collaborative work;
- use of concrete objects;
- use of real-life examples and
- repetition of mathematical concepts

An introspection of the above indicates that those strategies which were most beneficial to the student teachers' own learning experience emphasised social interaction. However, the various teaching and learning strategies used in the MIP did not have the same impact on all the *at risk* student teachers. Two distinct results that can be deduced from the tool-mediated activity were firstly, all the student teachers were optimistic in acknowledging their improved results. Secondly, the findings indicate that the teaching and learning tools that student teachers considered to be effective for their own learning of mathematics were also recognised as those that they would be inclined to adopt as mathematics teaching practitioners.

Finally, it may be concluded, that the classroom environment and strategies used in the MIP (refer Figure 4), were beneficial to the student teachers in two ways:

- they were able to engage in mathematics learning experiences similar to that of pupils in the school system. This was significant in providing the student teacher with pedagogical knowledge from an "insider" perspective; and
- these elements appear to jointly contribute to the improvement of their content knowledge of mathematics.

Student Teachers' Perceptions of Learning and Teaching Mathematics

Figure 4 underscores a distinction between the student teachers' perceptions of *learning* mathematics and the way they perceived the *teaching* of the subject. The findings indicated that the following factors contributed to the student teachers ability to perceive the learning of mathematics in a positive light:

- small class size;
- lecturer's attitude;
- varied teaching and learning techniques;
- individual attention;
- peer support;
- visible improvement in their mathematics results.

Evidence from the interviews revealed that a majority of the *at risk* student teachers who entered the MIP did so with a negative attitude and a fear of learning mathematics. The importance of both the constructivist teaching and learning strategies used in the MIP and the learning experiences of the student teachers contributed to the positive shift in their perceptions towards their learning and teaching of mathematics. The aforementioned is indicative that positive shifts in students' perception of mathematics are indeed possible albeit within different contexts.

Although a positive shift was noted in this study, there was a difference with regard to the student teachers' *learning* of mathematics and that of *teaching* mathematics. Only fifty percent of the student teachers interviewed conceded that they felt confident enough to teach mathematics lessons in their first year of practice teaching even though their academic results and attitude towards the subject had changed. Many of them remarked that they were not adequately prepared to manage mathematical queries that might arise in the classroom. Hopefully these first year students' confidence levels will grow by the time they graduate and enter the classroom. This important finding highlights an area that requires further exploration as it will be useful to understand why such inadequacies prevailed.

Notwithstanding the lack of confidence to teach mathematics, the findings do indeed reveal that the teaching strategies used in the MIP were imbibed by the students in that they recognized these strategies as techniques that could be used in their own teaching of mathematics during practice teaching and later as professional teachers. This was a significant finding as it demonstrated the MIP had an impact on student teachers' perceptions of their mathematics *teaching*.

CONCLUSION

Overall, the study provided some insight into how interventions can work in elevating the confidence of at risk students in a South African context. In particular, the study highlighted that it is indeed possible to ensure that newly qualified teachers return to schools with positive perceptions of mathematics.. Although the study has not been able to provide evidence of how these students will actually perform as teachers of mathematics, it does however set the stage for further investigation in this regard.

Finally, the findings of this study provided insight as to how the problems related to mathematics teaching and learning, can be overcome. Importantly though it should be noted that the MIP, like various other intervention programmes characterising the South African higher education landscape, are symptoms of the deeper consequences of apartheid education. The injecting of better equipped mathematics teachers into the school system, while important, needs to be located within an overhaul of the school system as a whole so that other problems such as lack of physical infrastructure, large class sizes, and paucity of teaching and learning resources are simultaneously addressed.

360 - History of the Law in the Curriculum: Analysis of an Experience

Ana Valéria de Figueiredo-da-Costa[1] and Agenor Pereira da Costa[2]

[1]University Estácio de Sá; PUC-Rio; [2]University Iguaçu, University Iguaçu; PUC-Rio

Abstract: Curriculum theories are part of a social and epistemological field. They show up in disputes for the power to select and privilege a certain knowledge over another, and to highlight one specific type of identity and subjectivity that is considered the "ideal" one from a hegemonic point of view. Thus, a curriculum is often the portrait of a determined time and its social, political, historical, cultural demands and many other demands found in the day-to-day life. Starting from the National Guidelines for Curriculum (DCNs) for the Law Graduation Programme, promulgated in 2004, the curriculum now requires the subject History of the Law to be part of the Basic Training Structure, and this aims mainly "to integrate the student in the field, stablishing relations between Law and other knowledge fields, covering, among other, studies that involve basic contents about Anthropology, Political Science, Economy, Ethics, Philosophy, **History**, Psychology and Sociology." (DCNs, art. 5, Section I, our emphasis). Starting from these premises, this paper aims to discuss and analyze the implementation of the subject History of the Law as a mandatory in the curriculum of the Graduate College of the Law. Following the orientations of the DCNs, the training areas, namely, Basic Training, Professional Training and Practical Training, must be included in the Pedagogical Project and in the curriculum of the College, through contents and activities. Therefore, this turns into a re-organization of the curriculum, considering the fact that the DCNs standardize and make the curriculum structure official; putting the actual subject in practice, though, has been crashing with the lack of a clear and objective system, and the professor of the subject has to search after many sources that only might be what a typical content of the subject really should be. The research methodology is the qualitative approach and analysis of content according to Bardin (1977), through the analysis of answers given by students of the Law to a short questionnaire. Some of the students who answered the questionnaire have had the subject in their first semester, and some did not have it because it was still not part of the curriculum when they were in their first semester. They are all from a private university in Rio de Janeiro. The study aims to contribute with the discussion about the formalization of the subject, in a time of globalization and uncertainty, considering, though, that these time provides us with a wider range of knowledge.

Key-words: Law Graduation – History of the Law – Higher Education

Curriculum theories are part of a social and epistemological field. They show up in disputes for the power to select and privilege a certain knowledge over another, and to highlight one specific type of identity and subjectivity that is considered the "ideal" one from a hegemonic point of view.

Starting from these premises, this paper aims to discuss and analyze the implementation of the subject History of the Law as a mandatory in the curriculum of the Graduate College of the Law. The idea of hegemony can be justified by looking it up in the dictionary (Aurélio, [s.d.]) which records that a theory, in its different meanings, is "a set of **not naive** knowledge that shows different degrees of systematization and reliability, and that is supposed to explain, make clear, interpret or **unify** certain phenomenon or events that are offered to the practical activity" (our emphasis).

The non- naivety of a theory creates a system of thought and control over the knowledge. This way, according to Silva (2003), the critical theories suggest a study about the knowledge as an issue of power this being the central issue that marks the split between traditional curriculum theories and the critical and post-critical theories in this field of study.

The studies about curriculum (the chronology presented here in this part of the study is based on the book *Documentos de Identidade* [Silva, 2003]) refer their origin to the book "The Curriculum", written by Bobbitt in 1918 in the United States. Bobbit is part of a generation that sees american education urgency in shaping the purposes and the ways of the people's education: who should graduate? What should be taught? What are the sources for teaching?

In short, Bobbitt was trying to answer what the main and *true* purpose of education was. This answer, in his thinking, had a technical purpose: the school should work as a factory, having specialized manpower according to the required tasks. The author also suggested, in thinking about the school as an industry, that

the results achieved in the teaching-learning process should be precisely measured and controlled. In fact, Silva (id.: 23) emphasizes this point of view when he affirms that "Bobbit's model was clearly made for economy. Its key-word was 'efficiency'".

Bobbitt's proposal brought echoes of Frederick Taylor's company organization model, which had scientific and efficient principles of administration for companies. Therefore, according to Bobbit's technical concept, education could become a scientific process, with beginning, middle and end monitored and controlled in all its aspects.

Bobbitt's model was consolidated with Ralph Tyler's studies, dated 1949. Without leaving the organization and education development perspective behind, Tyler develops a system for Bobbitt's idea in four elementary questions: 1 – Which goals are to be achieved? 2 – Which experiences should be provided in order to achieve these goals? 3 – How should these experiences be organized? 4 – How can we check if the goals were achieved?

Comparing to Bobbitt, Tyler advances when he identifies the sources of goals that should be taken into consideration in the educational process, namely studies about the students, about contemporary life, suggestions of the specialists in different subjects, besides others that were not considered by Bobbitt: Psychology and knowledge of academic subjects.

Previously to Bobbitt and Tyler's publishings about the technocratic model of curriculum, John Dewey writes in 1902 "The child and the Curriculum", book in which he shows his concern for the contruction of democracy. According to Dewey, education happens through practical experience of democratic principles that surround life in society. This way, there is no need of strict control over the "product" of education, considering that experience itself would direct the abilities that were awaken and experienced throughout the educational process.

Due to the social-economic order and politic established until then, it is from the 1960's and 1970's that Bobbitt and Tyler's models begins to get questioned as the only option for organization of school knowledge curriculum. With the upcoming of the movement New Sociology of Education discussed by Michel Young, originally in England, the "re-conceptualization of curriculum" movement gains strength, establishing the source of the critical theories as a new way of thinking the curriculum.

This theories criticize, emphatically, the dominating ways of knowledge and the established educational order, or in other words, the organization and elaboration of curriculum models. By comparing the traditional theories with the critical theories, it is clear, according to Silva (2003: 30), that

> the traditional theories were theories of acceptance, adjustment and adaptation. The critical theories are theories of distrust, questioning and radical transformation. According to the critical theories it is not important to develop techniques on **how to elaborate** the curriculum, but it is important to develop concepts that allow us to comprehend what **the function** of the curriculum is (author's emphasis).

If the traditional theories for the study of curriculum are based, among other characteristics, on technic-pedagogic aspects, such as teaching-learning process, the evaluation, the methodology, etc, in a very rational and extremely controlled way at each stage, on the other hand the critical and post-critical theories focus on the investigation of *how* these aspects are stained by the ideology and power of dominating groups.

Analyzing the orientations of the texts found in the National Guidelines for Curriculum (DCNs), the training areas, namely, Basic Training, Professional Training and Practical Training, must be included in the Pedagogical Project and in the curriculum of the College, through contents and activities that are supposed to be somehow connected.

Therefore, this turns into a re-organization of the curriculum, considering the fact that the DCNs standardize the curriculum and make its structure official; operating the actual subject, though, has been colliding with the lack of a clear and objective system, and the professor of the subject has to search for sources that only might be what a typical content of the subject really is. In the same area, we also see the history of school subjects as reported by Pessanha, Daniel and Menegazzo (2004, p. 27):

> the word subject, as it is known nowadays, is a recent creation (in Portuguese the word is the same as 'discipline'). In France, for instance, it was first recorded after the First World War, but its original idea remains: to discipline, to order, to control. The school subject would be the result of passing on the society's knowledge through a specific *filter*, so that at one point, after some time, it can no longer be related to the original knowledge. To Chervel (1990), the subject is the price paid by the society to culture in order to pass it on from one generation to another (emphasis on the original).

The authors emphasize the fact that the choice for a subject for a curriculum is not a free choice, or even less so disinterested; quite the opposite, such choice is deliberate and

> the epistemological framework of this field of research argues that school subjects are not reflex, vulgarization or pure and simple adaptation of the sciences. **As the history of a subject happens, it is transformed in its core, and these transformations make the analysis of its relation to society difficult**, giving the impression that only the internal factors, or those related to its science reference, were responsible for its history. **Finding the main points of this process, considering the forces and social interests at play in the history of certain subjects can enlighten their contents and their practices aiming to, if necessary, change them in order to meet new needs, instead of reproducing them as if they were neutral and independent** (Pessanha, Daniel & Menegazzo, 2004, p. 27; our emphasis).

Therefore, knowing how the subjects are established becomes a privileged socio-historical analysis field, full of meanings as it is a reflex of social disputes and arrangements.

The subject History of the Law

We take History of the Law here as a subject that meets the item of integration and comprehension of the legal phenomenon, considering the National Guidelines for Curriculum of the Graduate College of the Law (2004).

The fact that society is constantly changing is the source of vast research material for the science. Concerning the Law, a set of guidelines and rules that aim to prevent conflicts and create rules for the purpose of social peace, it is highly important that the graduates in this area seek to observe, interpret and compare past social events aiming improve the guidelines and rules in order to meet the aspiration of people in the present time.

Among other measures adopted by the National Guidelines for Curriculum (DCNs) that met what was stated above, we see that the History of the Law, optional subject until then, comes in order to contribute with the basic training and integrate the College of the Law, enhancing the legal knowledge and bringing the graduate to the category of operator of the Law, who nowadays lacks in the society, if this need is met, it will ensure a continuing training of this worker that is essential to the administration of justice in the Brazilian society. The DCNs (2004), article 5, profess

> the Graduate College of the Law must have, in its Pedagogic Project and in its Curriculum, contents and activities that meet the following interconnected training axis: I – Essential Training, which aims to integrate the student with the field, **stablishing relations of the Law with other knowledge fields, covering among other, studies that involve basic contents about Anthropology, Political Science, Economy, Ethics, Philosophy, History, Psychology and Sociology** (our emphasis).

Therefore, beyond being a mandatory legal measure, the subject History of the Law is a fundamental axis from an interdisciplinary point of view, providing the student with an integration of contents that will be material for a deeper and wider analysis of the legal fact, in the future practice of the students as operators of the Law.

This paper, through a qualitative research presented hereafter, aims to corroborate with the intention of the DCNs, considering that the data collected through the questionnaires will be able to help the receptivity of the History of the Law by the graduates, aiming to re-interpret the sources of the standards of living since the primitive people up to current days, without leaving behind the different societies that surround us, each one of them with its standards, providing a comparison for the improvement of the Law, Law that meets everyone's needs, regardless of their culture of origin.

The choice for the qualitative analysis came from the faculty's interest in the historical events that were introduced through the comparison of the standards of the past with the current standards, and the proof of what happened to the Law, reaffirming the human experiences that brought progress to the group, revealing itself as a compilation of legal facts that worked and perpetuated the life in group.

In order to have an argument to support the fact that we believe that what was said about the lack of interest in studying the History of the Law is relevant, it is necessary to add a comment about teaching History of the Law before the year of 2004, when the subject became mandatory.

Therefore we add that:

[...] studying the History of the Law is not very prestigious among the operators of the Law in Brazil. This subject has been on the curriculum of the Colleges of the Law only after the determination of minimum curriculum for the Colleges of the Law, established through an Ordinance of MEC nº 1886/94 (The ordinance mentioned was repealed by the DCNs – Resolution CNE/CES, n.9, September 29, 2004).

As mentioned above, the History of the Law, even though it was part of the curriculum, it did not awaken the students' interest, either for the lack of adaptations or for how it was taught, unattached from its origin, that is the society, in a historical time when the legalistic dogmatism was forced by the positivist formalism.

Thus, when we face this history made by those who dominated the historical events, namely, the winners, we see that they prioritize the past only, leaving behind the power to modify the learning methods at Law institutions; so it becomes necessary to innovate the teaching of the Law starting from the History too, trying to create opportunities for the Law to develop itself starting from the analysis, interpretation and comparison of the past and the present, aiming to ensure the future through the observation of the sciences that relate to the organization of life in society.

In the same realm, Wolkmer comments:

> we seek now to critically renovate the historiography of the Law, which comes from and happens in the dialectic of the material life and in the concrete social relations. It is about thinking the historicity of the Law – in what concerns to its historical development, its ideas and its institutions – starting from a re-interpretation of the sources of the past, viewing it through interdisciplinarity (economical, social and political) and through a methodological re-organization, in which the legal phenomenon would be described under a demystifying perspective.

As we can see, it becomes necessary to innovate the teaching of the History of the Law, understanding that what is essential in the concept of a orderly life should be included in the teaching at legal institutions, an analysis of the sources and the development of the Law, cultural technology shaped as phenomenon which leads life in society to social peace, mixing subjects, mainly History and Law.

An Answer coming from the questionnaires
This paper used the qualitative approach and analysis of content according to Bardin (1977), through the analysis of answers given by students of the Law to a short questionnaire. Some of the students who answered the questionnaire have had the subject in their first semester, and some did not have it because it was still not part of the curriculum when they were in their first semester.

Our intention was to work with the sample that was analyzed by this study, therefore 34 questionnaires got answered. Students of the Graduate College of the Law answered this questionnaire, and they were from the first, second and eighth semesters. In asking these students to answer the questionnaire, our intent was to establish points of agreement and/or disagreement in what concerns the subject History of the Law, considering that first semester students were attending the subject then, the second semester students had already completed it, and the eighth semester students had not had it in their curriculum at the university.

Next we will present some results and comment on them. The first question intended to probe the reasons why the students had chosen the College of the Law: what reasons led you to the College of the Law?

Chart 1: What reasons led you to the College of the Law?

Options	1st Semester	2nd S.	8th S.	Total
Family Influence	0	1	0	1
Opportunities for future work	2	7	5	**14**
Imposition of the family	0	0	1	1
Status	0	0	0	0
Dream Career	8	1	2	**10**
Chance of Financial Ascension	1	3	2	**6**
Others	Contest	0	Public Contest	2

We can see that the opportunities for future work together with the dream career are choices of both groups, but with a remarkable difference found among the freshmen, that have chose dream career. If we put together the option that states the possibility of professional ascension, it is clear that the students think about the college as a possibility of ascension through job opportunity. It is also noticeable in the options brought by

the students that, as the college goes by, the chances of noticing the job opportunities are higher, if we compare the numbers of this option for the first, second and eighth semesters.

The second question: what are your expectations concerning the College of the Law?, we were also interested in the students' projection about the college.

Chart 2: What are your expectations concerning the College of the Law?

Options	1st	2nd	8th	Total
Though it is long, I count on the financial reward afterwards	1	6	2	9
It does what is required: it gives extensive professional and academic knowledge	5	2	2	9
It is restricted to law	2	0	0	2
It is a college for public contests	5	4	7	**16**
Other	0	0	0	0

The students showed what we can also see in the day-to-day, in showing their expectations when they started this college, both the freshmen as well as the nearly graduates (in general, the College of the Law in Brazilian universities takes 10 semesters), that the College of the Law has been a very common requirement in public contests and even required at private companies.

However, what strikes us, beyond the aspect concerning finances, is the option that indicates the possibility of acquisition of professional and academic knowledge, which will help them to carry out their functions as operators of the Law in their future practice.

The third question aimed to get answers about the students' expectation concerning the course.

Chart 3: In what aspects has the course been meeting your expectations?

Options	1st	2nd	8th	Total
The subjects are interesting and dynamic	5	5	3	**13**
The subjects focus on day-to-day aspects	1	4	4	**9**
The subjects are interlinked and they complement one another	**7**	2	3	**12**
It hasn't been meeting my expectations	0	1	1	2
Other	0	0	0	0

We can observe through their answers that the students point that the subjects are dynamic and interesting, besides being interlinked among themselves; also that the subjects focus on day-to-day topics, which strengthens the idea of an integrated curriculum, as it is required nowadays. There were two students who indicated that the course has not been meeting their expectations, which requires further study in the future about this specific point.

The fourth question intended to understand the projections of the students about the course.

Chart 4: Before joining the College of the Law, you thought you would study:

Options	1st s.	2nd s.	8th s.	Total
Subjects related to the legal practice only	5	7	7	**19**
Subjects related to historical aspects and broader aspects concerning the Law	4	3	2	**9**
Subjects related to the BAR examination	0	2	1	3
Other	History; I didn't think of anything because I knew what I would study	Engeneering	--	3

We observe that their expectations are mostly related to the practice of the Law; however, there are bets on broader aspects related to the Law, including historical aspects.

Chart 5: From your point of view, how is the curriculum of the College of the Law structured?

Options	1st	2nd	8th	Total
All subjects are studied together	6	5	2	**13**
By study centers: Fundamental Training, Professional Training and Practical Training	3	2	4	**9**
By theoric work centers	1	1	0	2
By practice work centers	0	1	2	3
It does not follow an order	0	3	2	5
Other	0	0	0	0

Chart 6: Concerning the subject History of the Law, specifically:

Options	1st	2nd	8th	Total
The subject is interesting and dynamic	2	2	2	6
Subject focus on important topics	1	4	3	8
Subject interlinks and completes other subjects	7	1	3	**11**
Subject helps me to understand other subjects	1	5	3	9
Other	0	0	0	0

Chart 7: Did you think you would study this subject in the College of the Law?

Option	1st	2nd	8th	Total
Yes	7	12	8	27
No	4	0	3	7

Chart 8: You consider the History of the Law

Options	1st	2nd	8th	Total
Important for the training of the lawyer.	11	12	11	34
Not important for the training of the lawyer.	0	0	0	0

FINAL CONSIDERATIONS

The importance of the Law for peace in society is undeniable, especially societies that are in constant change and that lack legislations that come along with the changes. Concerning History of the Law and its being mandatory in the training of lawyers, we can see through this research that the Ministry of Education has rightly met the faculty's expectation when it confirmed the importance of such subject and made it mandatory, in a first instance, in the Graduate College of the Law.

Also, considering the history of school subjects, they are created as the materiality of the representations of ways of thinking what the necessary knowledge is to each training, related to the context in which it is conceived and operated.

As the authors mentioned here state, the choice of which knowledge is "valid", organized as a curricular component, is the result of discussions that happen in the different instances that rule the formal schooling process: legislation, curriculum, the future practice of the profession, among others.

Therefore, studying the subject History of the Law and its official insertion in the curriculum of the College of the Law give us hints to comprehend, more broadly, that nowadays the practice of a profession requires a knowledge that hinges different aspects of the same objects, bringing about a wider range of options for the student, future operator of the Law.

Besides this point of view, the subject makes us understand also how a curricular component gets inserted in the school culture in its materiality, since there is not enough formal material for the professor of this subject to rely on, because it is being gradually built in the teaching practice, on the floor of the school, in its daily routine.

Research, Knowledge and Change

4 - Tracking Beginning Teachers' Orientations of Diversity – Why do they Change?

Vijaya M. Dharan

School of Educational Psychology and Pedagogy, Victoria University of Wellington, New Zealand
vijaya.dharan@vuw.ac.nz

Abstract: Diversity is a rapidly growing universal phenomenon that has educators trying to grapple with ways to prepare and support teachers to be responsive to the varying needs of students' learning. While initial teacher education (ITE) programmes globally are making significant strides to ensure that student teachers are provided ample opportunities to critically examine their own beliefs and orientations towards diversity, it is only when they begin actual teaching in schools that the "rubber hits the road". This qualitative study examined the perspectives of seven beginning teachers towards student diversity during the first 6-18 months of their first teaching positions. Findings describe how their attitudes towards student diversity changed under possible influences of school culture. These teachers narrowed their definitions of diversity to focus solely on academic achievement levels, with implications for teacher education and support for beginning teachers to better reflect the multiple dimensions of diversity.

Keywords: Beginning teachers; Diversity; School culture; Initial teacher education

INTRODUCTION

The field of education internationally is explicitly striving to make schools and education available to all children and young persons as the demographic profile of classrooms is becoming increasingly diverse. *No Child Left Behind* (USA)[152], *Every child matters* (UK)[153], and *Ensuring participation, engagement and achievement of all young person* (NZ)[154] are political mandates for schools to provide quality learning opportunities for **all** children and young persons. In New Zealand, where this study was undertaken, it is predicted that by the middle of this century more than two-thirds of children will be non-European (Love & Waitoki, 2007). This changing cultural landscape of New Zealand schools has led to strategies such as *Ka Hikitia*[155] and the *Pasifika Education Plan*[156] being implemented by the education ministry to improve the access, participation and achievement of Māori and Pasifika[157] students. In another pioneering step in its commitment to equity the *New Zealand Disability Strategy*[158] validates the sociological model of disability with an underpinning vision of a fully inclusive society in which **all** people have access to the benefits that society offers.

These political mandates and strategies, statistics and emerging research are clearly signalling, if anything, a radical revamp of initial and in-service teacher education provision, and a more conscious and deliberate shift in ways that schools accommodate the range of diversity to provide a culture that strongly embraces the notion that **all** students can learn. While initial teacher education can provide opportunities for student teachers to critically examine their own dispositions and epistemologies towards diversity, this study identifies the contextual influences that are perceived by beginning teachers to re-organise their beliefs, values and attitudes towards diversity.

DIVERSITY

The phenomenon of diversity, despite its pervasiveness, is both complex and prone to subjective interpretations. The extant literature uses terms such as "multicultural education" and "education for

culturally and linguistically different children" to denote diversity. Equally ethnic, social class, and disability groups are becoming increasingly vociferous and resisting marginalisation by mainstream educators and policy makers (Riehl, 2000), thus reminding us that diversity has more dimensions to it than culture and language alone. This complex concept therefore, is used by some educators to highlight and critique the dominant culture and the marginalisation of silent voices, and by some others as a progressive step in education for social justice (Bonal & Rambla, 1999). However ambiguous or complex diversity may be, current and future teachers will need to move beyond superficial awareness to a more critical and sophisticated understanding of the multidimensional nature of diversity to underpin their pedagogical practices. (Adler, 2011; Alton-Lee, 2003; Banks, 2008; Bishop, Berryman, Cavanagh, & Teddy, 2008; Gay, 2010, Fraser, 2008; Grant & Sleeter, 2009; Meyer, Bevan-Brown, Harry, & Sapon-Shevin, 2007).

School culture
It can be safely assumed that schools must have an ethos of care where all students are valued to enable teachers to be responsive to the diverse needs of their students. The ethos or the school culture is the "norms, values, beliefs, traditions and rituals built over time" that builds a set of "informal expectations and values" that in turn shape the ways people in a school "think, work and act" (Peterson & Deal, 1998, p. 28). The underlying values and beliefs often operate subliminally but they underpin all actions of staff and clearly send the message that this is "the way we do it around here" (Nias, Southworth, & Yeomans, 1989). But rapidly changing demography of students has made scholars strongly advocate for challenging existing norms, values and practices in schools that continue to marginalise certain students (Ainscow & Booth, 2000; Bishop et. al., 2008; Grant & Sleeter, 2009). For beginning teachers who are positioned in this changing landscape of classrooms, being responsive to the heterogeneity of students is not only overwhelming but also challenging; as juxtaposed with existing school culture are the individual teachers' beliefs, attitudes and knowledge frameworks that inform the ways in which they respond to diversity (Bonal & Rambla, 1999; Cochran-Smith, 1997; Wideen, Mayer-Smith, & Moon, 1998).
The settling of beginning teachers into the realities of teaching depends on a number of contextual factors that are unique to each school (Kelchtermans, Ballet & Piot, 2009; Kelchtermans & Ballet, 2002; Langdon, 2007). When beginning teachers assume the responsibility of their classrooms, "they become part of a new and different reality" (Cole, 1992, p. 366). It is the stance that staff take in thinking about the students (Fried, 2001) and the wider ethos of schools that have a significant influence on beginning teachers (Wang, Odell, & Schwille, 2008; Williams, Prestage, & Bedward, 2001). Their process of *learning to teach* will change depending on the idiosyncratic practices of the schools that they are in and the nature of professional support they receive (Bergeron, 2008; Education Review Office, 2003; Olson & Osborne, 1991); a period in which they resort to mirror the prevailing discourses of their schools (Parks, 2010).

RATIONALE FOR THE STUDY
Recent research on examining epistemological beliefs of trainees (Adler, 2010; Tanase & Wang, 2010) and their dispositions towards diversity (Mills & Ballantyne 2010; Kidd, Sanchez & Thorp, 2008) have reiterated the importance of developing positive dispositions among student teachers through critical dialogues and relevant field experiences, and empirical research on initial teacher education to prepare teachers to be responsive to diversity has gained substantial momentum (Bishop et.al. 2008; Gay, 2010; Sleeter, 2001& 2009). Over the years there have also been studies that examine the impact of contextual factors on the biographies and pedagogy of novices (Flores, 2007; Flores, 2001 & 2006; Kelchtermans & Ballet, 2002); the nature of professional guidance and peer support within schools (Achinstein & Barrett, 2004; Langdon, 2007; Wang, Strong & Odell, 2004), and the extent of supportive school leaders (Flores, 2004; Langdon, 2001; Riehl, 2000). There has been fewer longitudinal research that followed student teachers into their first year of schooling, some of which identified the extent of tensions and challenges for novices who wanted to teach 'against the grain" (Averill et.al.,2009; Flores, 2007, Kuzmic, 1994, Rust 1994). Nevertheless, empirical studies that examine the day-to-day lived experience of beginning teachers over a period of time are fewer (Patrick, 2003; Sleeter, 2001), as is the literature that explores the impact and influence of school culture on beginning teachers' beliefs and attitudes (Pajares, 1992; Raths, 2001), particularly about diversity in their classrooms. This study contributes to this limited literature with an overall research objective of: *Do schools' cultures, practices and policies influence beginning teachers' beliefs, attitudes and practices in relation to student diversity?*

METHODOLOGY

In the unpacking of the major research objective, the terms "dispositions" and "orientations" were deliberately chosen, particularly as dispositions refer to the tendencies in which people make judgements and act in particular circumstances based on their beliefs (Johnson & Reiman, 2007; Villegas, 2007). "Attitudes" were examined in the context of orientation, which refers to "positioning"[159], as the term better reflects the stance of these beginning teachers. The questions guiding the enquiry were:

1. *What were the initial dispositions and orientations of beginning teachers towards student diversity?*

2. *How did schools' ethos shape the beginning teachers' initial dispositions, orientations to diversity, and their pedagogical practices?*

"The questions we ask of the empirical world frame what we know of it" (Charmaz, 2005, p. 509). The number of conversations and anecdotal comments on "how we do things here" over the years of my working as a teacher and school psychologist formed the basis of my research objective. The study used a grounded theory approach and was located within a constructivist paradigm since the focus was on the meaning-making activity of beginning teachers (Crotty, 1998). Schools with varying profiles were selected from one region in the country. (**Appendix 1).** The seven beginning teachers were from the same ITE, but different cohorts. Five of them were Pākehā[160], one Māori and one immigrant. Their participation in the study ranged from 6-18 months. (**Appendix 2).** Primary sources of data[161] that informs this paper include interviews with beginning teachers, tutor teachers and school principals; observations in classrooms, PRT[162] meetings and Syndicate[163] meetings. Principals were interviewed once at the beginning of the study, the tutor teachers were interviewed at the beginning of the study and at the end if they still continued to be the mentors. The beginning teachers themselves were interviewed periodically – two to six times depending on the length of their participation.

FINDINGS

Trainees enter teaching programmes with their own experiences in learning situation which is repeatedly referred to as *apprenticeship of observations.* The motivation to teach for these participants stemmed from both positive and negative school experiences. These novices were appreciative of their initial teacher education (ITE) programme which had exposed them to cultural and other aspects of diversity. More importantly, the various field placements were seen as providing them with valuable exposure to the ethos and culture of different schools. This "organisational literacy" played a key role in deciding their places of work. Six out of the seven beginning teachers secured jobs in the school that they had their final practicum placement.

Initial Perceptions

The complexity of the phenomenon was evident in the participants'' responses. For most of them though diversity was a 'hard' concept, it was about uniqueness and *individual* differences. They perceived every student to be an individual. Some of their understandings were expressed as follows:

> *Kind of more individualism. Like treating every child as an individual, rather than you are a Māori or you are a Pacific Islander, you are this and you are that.*

> *Diversity to me is a lot of difference, not all the same.*

However, in unpacking their understanding of *individuality* and *uniqueness,* they began to identify various dimensions of diversity such as culture, socio-economic status, gender, age, spirituality and academic learning abilities. There was a deeper understanding articulated by the Māori beginning teacher who talked

[161] World limitations restrict expansion of the entire range of intended data gathering methods and their limitations which will be expanded upon in a future article to be submitted to the ISATT publication of Teaching and Teaching: Theory and Practice.

[162] Beginning teachers are Provisionally Registered by the New Zealand Teachers Council for the first two years of teaching and are assigned tutor teachers(mentors) with whom they have weekly or fortnightly meetings.

[163] Primary schools in NZ are generally organised into junior, middle and senior syndicates. Each syndicate has a leader and between 2-4 teachers and meet regularly.

about the dimension of life experiences which can be totally different although two children were from the same culture:

> *If somebody has got brown skin and have a Māori name, do not throw words of te reo at them because they may not know [the Māori language].*

It was apparent that these beginning teachers had a broad understanding and orientations towards diversity and more awareness of cultural diversity as they stepped into schools of their choice.

Perceptions 12-18 months later

A year and more after stepping into a "new reality" what became apparent was the orientations and dispositions of these beginning teachers towards diversity in terms of their pedagogical practices were focused almost solely on students' academic learning abilities. Knowing their academic capability was seen as a way to get to know and reach out to the students in their classes. They voiced it through comments like:

> *I think I am still trying to figure out how to reach each of them. I think that at the moment it is still the major focus – is trying to figure out where they are with their achievement and how to group them accordingly.*

> *I am really keen use assessment to draw from it. Because I think that is the only thing you have got as a teacher.*

What was distinct a year and more later was the shift in their perceptions of individual differences. Now, individual differences took a uni dimensional focus, the academic learning abilities of students, while other dimensions including culture, seemed rather invisible. The predominance of pedagogy based on ability groupings was further evident during the classroom observation sessions. Beginning teachers were asked prior to each classroom observation which was spread across literacy, numeracy as well as other curriculum areas to identify specific aspects of their classroom practices that were indicative of their responsiveness to diversity in their classrooms. In all instances the researcher (author) was asked to observe ways in which tasks were modified for the top, middle and lower groups.

Influencing factors

To understand the narrowing of their perceptions of diversity, it is necessary to understand their organisational contexts, structures and their ways of working that determine the beginning teachers' professional practices (Kelchtermans & Ballet, 2002, Flores, 2001; Nias et al., 1989).

Perceptions of school leaders

The principals in this study had a range of views on the nature of growing diversity in their schools. They perceived a range of culture, academic learning abilities and socio-economic differences among students. Four out of the five principals acknowledged the growing multicultural nature of their communities; only one perceived the school to be homogenous; but they emphasised disparity among learning differences as an important aspect of diversity. The gaze of practicum was bi-directional as the principals used the placement opportunities to select their future teachers and appointed novices whose dispositions towards learning and teaching aligned with the existing culture of their schools (Langdon, 2001 & 2007).

Tutor teachers (mentors), who play a crucial role in the induction process of beginning teachers also emphasised culture and learning abilities as the key dimensions of diversity that existed in their schools. They were similar in their perceptions to the principals in that they perceived a huge diversity among academic learning abilities of their students. While they were positive about the cultural diversity their focus and concerns were about the steady increase in the number of students having learning difficulties in schools. In one of the schools, parental expectations were perceived to be the reason behind the focus on the sole dimension of academic abilities.

> *Parent expectations here [are] huge. They don't want to see their children making models. They want to see results. They want to see their children reading at their age level or above.*

PEDAGOGICAL PRACTICES

As planning[164] is one of the key aspects of a teacher's role, the beginning teachers were asked how they planned for diversity in their classrooms. From their responses it appeared that they perceived planning to be about a topic rather than specifically planning for the range of diversity of students in their classrooms. One of them was unsure what planning for diversity was about:

> *I do believe that it [diversity] is individual, but I can't plan for all. I didn't even try planning individually. Like in my unit plans and things for maths, I write down what is there and not what I am going to do about it.*

This focus on content made another participant remark:

> *Since I already developed numeracy and literacy plans last year with learning intentions, I will be using the same units this year.*

Observations during unit planning sessions in some syndicate meetings also showed that discussions were more topic and content focused. In terms of planning the actual teaching of the content, the beginning teachers were guided to focus on the academic abilities of students. Observations in PRT[165] meetings also revealed an emphasis and ongoing focus on comparing student performances against normative data which appeared to further strengthen the beginning teachers' focus on academic abilities of students. Thus as a way of managing the complexities of organising and teaching a class of diverse learners, these beginning teachers were inculcated into practices of establishing ability groups especially in the core curriculum areas of maths and literacy.

> *For maths and literacy yes, they are grouped from their assessment.*

> *[They] are grouped on ability in maths and reading.*

Therefore, from early days their pedagogy centred on ability groups which later began permeating their ways of thinking and working. School policies did not influence their pedagogy, as there were no expectations that they would be familiarise themselves about wider school policies on diversity. One of the principals went to the extent of saying: 'To be perfectly blunt they [beginning teachers] shouldn't be bothered about it, at the beginning'.

DISCUSSION

Though they are novices to the teaching profession, beginning teachers are not passive actors that slip into a new role (Kelchtermans & Ballet, 2002); rather, they are inseparable from their personal biographies, knowledge framework, beliefs and attitudes to teaching (Bonal & Rambla, 1999; Flores, 2007; Lortie, 1975; Wideen et al., 1998). Likewise, these beginning teachers' dispositions and orientations towards student diversity were shaped by a variety of experiences – family, education including initial teacher education programmes, their new classrooms and, for some, their work experiences prior to embarking on a teaching career. Among these experiences, the beginning teachers perceived their initial teacher education and associated practicum experiences as being pivotal in shaping and broadening their knowledge of the extent of diversity in schools and classrooms.

When they began teaching these novices perceived diversity as "social categories" rather than as issues central to their pedagogy (Milner, 2005; Paine, 1990) and the dimensions of culture, learning abilities and spirituality were articulated as a global concept of uniqueness. This global notion of diversity seemed to give them a feeling of homogeneity and structure while they were coming to terms with the various demands of being a teacher. With a range of predisposed views and orientations to certain aspects of diversity, these beginning teachers had entered schools with their own priorities and practices. As Flores (2001) observed:

---

[164] As part of preparing the unit plans, lesson plans and weekly plans.
[165] Provisional Registered Teacher meetings which were a one-to-one weekly session between the novice and the tutor teacher (mentor).

The transition from student to teacher/trainee entails the recognition of the new institutional role and the awareness of a wide array of complex issues related to the organisational, formal and situational dimensions of teaching. (p.139)

However, a year to 18 months later, a similar theme began to emerge in the perceptions of the five beginning teachers employed in four different schools. It became apparent that the dimension of academic learning dominated their "thinking, knowing, feeling and acting" (Feiman-Nemser, 2008). Very early in their practice groupings according to academic learning abilities formed their frames of reference to adapt the classroom programmes mirroring existing organisational practices (Parks, 2010), carrying and transmitting assumptions and notions of ability as a defining character (dimension) of individuals (Tickle, 2000). As they began to fit in and grow in the role of a teacher, these novices were trying to come to terms with the values and existing practices of their schools and were focused on assimilating sooner than later.

Nevertheless, educational scholars over the years have emphasised the multifaceted profile of diversity in that students are not homogenous but are influenced largely by their life experiences, gender, race, ethnicity and social class background (Alton-Lee, 2003; Banks, 1996; Villegas & Lucas, 2002), and that teachers should be constantly aware of the interplay of these multiple dimensions. Meyer, Bevan-Brown, Park, and Savage (2009) and Meyer et al. (2007) emphasise the fact that students have more than a unitary dimension to their diversity and for teachers to be able to include the differences students bring they must be able to engage in socially critical reflection. However, for these beginning teachers the emphasis on assessments, identification and grouping of students according to their academic learning abilities in their schools reiterated by tutor teachers who are conduits for induction (Cameron, Baker, & Lovett, 2006; Langdon, 2007), tended to reinforce a unitary dimension of diversity and promoting individual differences. The extent of collaboration and time constraints during professional meetings also appeared to be a barrier that hindered reflexive dialogues that examined the underlying orientations of both the beginning teachers and mentors regarding pedagogy for diversity and equity (Achenstein & Athanases, 2005), and restricted to addressing immediate needs and functional competencies (Feiman-Nemser, 2001).

The nature and extent of deep-seated learning that allows beginning teachers to move beyond the stage of coping depends entirely on the culture of the school context (Feiman-Nemser, 2003). The continuous focus on assessments and content planning appeared to narrow the perceptions of diversity as being a uni dimensional phenomenon in terms of pedagogy creating a hierarchy among the multi dimensions of individual differences. One could see the process of acculturation potentially developing a "belief of one right way of doing things" (Penetito, 2010, p 91) and perpetuating "existing beliefs, standards and practices in schools" (Rippon & Martin, 2003. *p. 213).*

IMPLICATIONS

This study, though small, has implications for both ITE and the way beginning teachers are guided in learning to teach. Increasingly ITE programmes are required to place greater emphasis on gauging the beliefs and attitudes of pre service teachers towards diversity (Gay, 2010; Johnson & Reiman, 2007), and incorporating learning situations in initial teacher education programmes that heightens their awareness of diversity (Adler, 2011; Tanase & Wang, 2010). It is imperative that schools must also expose beginning teachers to develop rich, dynamic and deep seated knowledge of learning that stretches beyond normative teaching behaviours to be truly responsive to all students (Flores, 2007; Grant & Sleeter, 2009). Continuing to have a simplistic notion of individualising diversity not only merges two important but opposing constructs of equality and diversity (Bonal & Rambla, 1999) but also does not allow for a more sophisticated understanding that "for each individual student the intersection of social class, ethnicity and gender can markedly influence cultural practices, preferences and prior experiences" (Alton-Lee, 2003, p.5).

CONCLUSION

This study has shown that while initial teacher education can create a broader conceptual understanding of diversity, existing professional practices of schools have an immediate and lasting influence in the acculturation period of novices. In this study these teachers narrowed their definitions of diversity to focus solely on academic achievement levels, rather than orienting their pedagogy with an understanding that learning is inextricable from one's culture, identity and lived experiences. Therefore to be responsive to diversity it is critical that the initial period of learning for novices should be transformational process, a time during which they share and exchange pedagogical expertise through collaborative communities (Flores, 2007), where existing beliefs and attitudes are examined and reconstructed. In New Zealand, the official

curriculum (Ministry of Education, 2007) explicitly outlines the values of embracing diversity and ensuring equity to be "encouraged, modelled and explored" in schools (p. 10). At a time when teaching from a neutral stance to diversity by assigning a simplistic sameness to all students can no longer be acceptable, the "Effective Teaching Profile" (Bishop et al, 2008)[166] and the Registration criteria[167] are two other professional tools to support beginning teachers in New Zealand to better respond to diversity. The quintessence of change lies in a systemic approach.

LIMITATIONS
The fact that the participants were from a single ITE programme and the varying duration of participation were limitations of the study. Understanding the extent of influence of school policies on diversity was not possible as there were no expectations in these schools for the beginning teachers to be familiar with them.

FUTURE RESEARCH
While examining initial dispositions, orientations, beliefs and attitudes are critical, this study has shown that there are factors currently within schools that have more potential to influence in shaping beginning teachers' dispositions and orientations to diversity. The data source for the study were subjective – primarily the perceptions of beginning teachers. It is possible that in the early stages of teaching these beginning teachers echoed their institutional views rather than delving deep into their own thought processes. A longitudinal approach can overcome the conformity of the "survival" period and may lead to better understanding of the developing orientations and ongoing dispositions of novice teachers towards diversity in their classrooms. This is particularly so as the process of learning "the way we do things here" seems to be an accepted norm of learning to teach as voiced by a beginning teacher in the study:

> *I have just kind of been subsumed into the school. I guess I feel very much at home here ---and in making those same kinds of comments that [tutor teacher] would make.*

Another area that requires further in depth research as highlighted in this study is the impact of practicum gaze particularly at a time when teacher educators are urged to train teachers to "teach against the grain".

[168] Data were taken from the Ministry of Education Institution profile at commencement of the study in January 2007 & 2008. The table does not include subsequent changes to any of the information presented below.

[169] This is a ranking based mainly on the socio-economic index of the area in which the school is located. This ranking is one of the determinants of Government funding to schools.

[170] SN – Special Needs refers to students who are achieving at a lower academic level than their peers and require additional support to meet their learning needs.

[171] This refers to students who come from islands in the Pacific region. The majority of them are from Samoa, with smaller numbers from Tokelau, Niue, Tonga, Tuvalu and the Cook Islands.

21- Teaching Mathematics Using Inductive Approach Enhances Learning: A case of Grade 11 Classes in Gauteng Province, South Africa

Moses Makgato[1] and Tshidiso P. Masebe[2]

Department of Mathematics, Science and Technology Education, Tshwane University of Technology, South Africa
[1]makgatom@tut.ac..za
[2] masebetp@tut.ac.za

Abstract: The poor achievement of students in mathematics in general, and particularly in respect of 'linear functions', is attributed to, among others, the traditional way of teaching, which is deductive approach which emphasises symbolism, manipulative skills and rote memorization of facts at the expense of the development of concepts and problem solving abilities. The critical outcomes as outlined in the mathematics curriculum document, promote a balanced view of reality and deep conceptual understanding by requiring development of all learners' problem solving abilities. In this study a pragmatic evaluation in a form of pseudo experiment complemented with a qualitative investigation was used. The participants consisted of 122 Grade 11 learners from two high schools in the Tshwane west region, Gauteng Province. Sixty one (61) students from one school was used as experiment group, while other sixty one (61) students from another school was used as control group. In addition, four students from the experimental group, together with their mathematic teachers were interviewed. The results has shown that inductive teaching improved the learning achievement of the Grade 11 in experimental group with regard to 'linear functions'. In conclusion, we argue that inductive teaching when applied properly would cater for the mathematical learning needs of learners, because it affords them the opportunity to construct a better understanding of function.

Keywords: Teaching mathematics, inductive approach, learning functions

INTRODUCTION

The Third International Mathematics and Science Study (TIMSS), as the largest, most comprehensive and rigorous international comparison of education ever undertaken, is highly significant in the context of mathematics and science education in South Africa. It has provided us with baseline information and benchmarks for future developments in mathematics and science education at national level. Several studies (e.g Makgato & Mji, 2006; Howie, 2003) reported on the poor performance of students in mathematics and science. For example, in a study conducted by Makgato and Mji (2006) it was found that some of the factors associated with poor understanding and low achievement of students in mathematics was related to teaching strategies and content knowledge (CK) of teachers. In that study a one student said the following *"my problem is that the teacher is too fast and I do not understand Maths, I want someone who is patient and does not get angry with me"* . Mapular's concerns could be addressed through the knowledge of the scope and correct teaching strategies (Huckstep, Rowland & Thwaites, 2005). In a study conducted in Mozambique, where deductive approach was used to teach mathematics students could not get clear relationship between concepts (Vos, Devesse, & Rassul Pinto, 2007). As a result, many Mozambican students rehearse mathematics formulas without attaching meaning to them and understanding them conceptually, leading to short-term retention and low achievement (ibid).

The poor achievement in mathematics in general, and particularly in respect of 'linear functions', is attributed to, among others, the traditional way of teaching, which is deductive approach which emphasises symbolism, manipulative skills and rote memorization of facts at the expense of the development of concepts and problem solving abilities (O'Callaghan, 1998). In addition, under-achievement in mathematics occurs when teachers over-indulge in using deductive teaching approaches in their teaching, resulting in little regard for learners' abilities and learning styles, and disallowing them an opportunity to benefit from inductive teaching which proceeds from the particular to the general (Masebe, 2009). Using the traditional teaching of deductive approach, Vos et al (2007) found that students learn to memorise definitions, formulas, algorithms, or procedures needed for the immediate solution of mathematical exercises.

The use of an inductive approach in teaching algebra concepts, of which "function" is central, is in line with the changes in the education system in South Africa. The critical outcomes in general, as outlined in the mathematics curriculum document, and the first critical outcome in particular, promote a balanced view of

reality and deep conceptual understanding by requiring development of all learners' critical thinking powers and their problem solving abilities (DoE, 2003; Van der Horst & McDonald, 1997). O'Callaghan (1998) argues that the essential feature in the construction of mathematical knowledge is the creation of relationships, which is the hallmark of conceptual and relational understanding and problem solving. In the context of the school mathematics curriculum, functions are particularly useful tools in problem solving as they are often used to describe relationships.

This paper report on the influences of using inductive approach as a teaching strategy on the achievement of students in understanding mathematical 'linear function' in grade 11 classes. The teaching and learning of mathematics in South African schools continue to experience grave problems leading to low quality learning and frequent failure (Kanjee, 2004). DoE (2000) indicated a drop in overall percentage in mathematics from a 55,7% pass in 2005 to a 52,2% pass in 2006. Hence, this research seeks to contribute towards finding viable and durable solutions to the problems regarding the performance of students in mathematics. In particular, mismatches between traditional teaching and learning of mathematics are blamed for the problems encountered.

Conceptual framework and different representation of function
The conceptual framework is essentially the attempt by the researcher based on the ideas of Thompson (1985), Kaput (1989) and Fey (1992) as quoted by O'Callaghan (1998:24) to impose a structure and organisation onto the meanings associated with the function concept. The model chosen for this study is one adopted by O'Callaghan (1998). This model identifies and applies four competencies of modelling a function, interpreting a function, translating and reifying a function. This model best describes the conception of a function concept. It must be emphasized that the model accounts for components of knowledge relevant to the function concept and forms a basis of analyses for learners' conceptualization of functions, and is not a prescription of how functions can be learned (O'Callaghan, 1998).

Modelling
Modelling involves the transition from a real-life experience to a mathematical representation of that experience. We recall the situation of the tomatoes vendor. The problem was to identify the best possible way to maximise the profit from the sales of tomatoes to make a decent living. The process entailed the use of variables and a function to form an abstract representation of the quantitative relationships in the vendor's situation (O'Callaghan, 1998). This component further divides into a number of subcomponents depending on the representation system used to model the situation. Modelling real-world situations to help organize the physical world is one of the most common uses of functions. O'Callaghan (1998) concedes that the perception of functions as an appropriate tool in this regard is a *sine qua non* condition for making any sense of the function concept.

For example, Mapula buys a crate of tomatoes from which he gets 10 packets of five (5) in a packet. Find the following:

a) The total number of tomatoes in five (5) crates;

b) The number of crates Mapula buys if he obtains 150 packets.

c) If a crate costs R50 and the monthly rental of the stall is also R50, write the profit per crate of tomatoes as a function of x, where x represents the number of packets of tomatoes sold if each packet sells for R10.

The solutions of the above questions are:

a) The number of tomatoes in five crates $= 5$ crates $\times$ 10packets / crate $\times$ 5 tomatoes / packet = 250 tomatoes.

b) To obtain 150 packets, Mapula will need to buy three (3) crates of tomatoes.

c) The profit per crate is defined as the difference of the selling price per crate and the cost price.

$\therefore$ Profit $= 10x - 50$.

Interpretation

Interpreting is the reverse process to modelling. It gives functions in different representations in terms of real-life applications. Interpreting is the second component of the function model (O'Callaghan, 1998). This component can be partitioned into subcomponents, which would correspond to the three most frequently used representations for functions namely equations, tables, and graphs (O'Callaghan, 1998). O'Callaghan (1998) contends that learners could be confronted with problems that require them to make different types of interpretations of functions or to focus on different aspects of the graph, for example individual points versus global features.

O'Callaghan (1998) argues that learners have trouble with the way they operate with and conceptualise functions. The sources of these difficulties evolve through their developing and integrating structures on both the levels of specific values and overall patterns of behaviour.

Translation

Translation refers to the ability to move from one representation of a function to another. From the above statements the mathematical model may be represented by various systems. The five core representational systems that a function can translate among are contextual, graphical, equations, tabular and language use (O'Callaghan, 1998; Van de Walle, 2004).

Let us suppose that the table 1 below gives the value (V), in rands, of a Hyundai Getz 1.4 GL car for the different number of years (t) after it is purchased.

Table 1: Number of years and the value in rands

Number of years (t)	Value (V) in rands
0	117600
2	95200
4	72800
6	50400
10	?

We use the information in the table to write a symbolic rule expressing V as a function of t, and use the rule to determine what the price of the car will be ten years after its initial purchase.

Reification

Reification defines the creation of a mental object from what was initially perceived as a process or procedure (O'Callaghan, 1998). In simple terms, reification refers to the treatment of something abstract as if it existed as a real and tangible object. This mathematical object possesses the property that one can operate on by other processes such as transformation or composition. Arguably, reification is a truly difficult process that entails a conceptualisation of functions achieved by few learners (O'Callaghan, 1998).

Suppose that Mapula works forty hours a week at a furniture store, earning a R220 weekly salary plus a 3% commission on sales over R5000. Given that Mapula s sales is represented by x, then his commission as a multiple of his sales will be represented by the function $f(x) = 0.03x.$ The other condition placed on Mapula commission is that the sales should be more than R5000. Represented as a function we have $g(x) = x - 5000.$ Mapula's commission as function of his sales (x) is represented by the composition of functions $C = (f \ o \ g)(x) = 0.03x - 150.$ In this example the commission could be attained once the sales have exceeded R5000. The amount of R5000 is the break-even.

Inductive teaching approach

Inductive teaching approach or inquiry-based learning enhances the learner to be able to do things on her or his own. This is precisely the primary purpose of teaching. Inductive teaching encompasses strategies such as problem solving, investigative learning, learning by discovery and cooperative learning. Inductive teaching approach expends inductive reasoning as a process skill. Inductive reasoning is based on the principle of *a posteriori* logic, which proceeds from a particular set of causes or facts of experience to the general law, or principle (Van der Horst & McDonald, 1997). An *a posteriori* logic refers to using facts or observations you know now; to form a judgement about what must have happened before. Felder and Henriques (1995) contend that Inductive reasoning is a reasoning progression that proceeds from particulars (observations, measurements, data) to generalities (rules, laws, theories). An example of an inductive reasoning is the

observation that when one adds two odd numbers the sum is an even number (Moodley, Njisane, & Presmeg, 1992).

For example, consider the following addition of odd numbers:

$1+3=4, \quad 3+5=8, \quad 7+9=16.$

We note that although the numbers 1 and 3, 3 and 5, 7 and 9 are odd, their sums 4, 8 and 16 respectively, are even numbers. Repeating the exercise with larger odd numbers, this is still true. For example, consider the following additions:

$115+117=232, \quad 253+345=588.$

In all the cases, these particular examples suggest the conjecture: "*The sum of any two odd numbers is even*" (Moodley *et al.*1992).

In the inductive reasoning individual examples are used to arrive at the general principles underlying them. Examples that do not fit the idea (non-examples) are helpful in confirming the idea (Huetinck & Munshin, 2004). Conjectures are arrived at after a number of steps or procedures (Felder & Henriques, 1995:7). Inductive reasoning is extensively used in mathematics as a method of proof where primarily it serves the roles of discovery and verification (Felder & Henriques, 1995).

Let us consider an example taken from Learning Outcome 1, Number and Number Relationships in mathematics curriculum (DoE, 2003), where induction is used twofold, for confirmation and as a method of proof. The example first requires the use of reasoning to confirm the formula $\sum_{i=1}^{n} i = \frac{n(n+1)}{2}$, then we apply mathematical induction as a method of proof to prove the statement true for all natural numbers n. The proof using mathematical induction as a method of proof requires three steps that involve proving the statement or proposition true for one natural number, assuming the proposition true for a number of terms or natural numbers, and proving the proposition true for numbers beyond for those assumed true. In this approach induction is used as a method of proof.

RESEARCH METHODS

The population consisted of learners and teachers from Grade 11 classes in the Gauteng Province, Tshwane West Region. The sample consisted of 122 Grade 11 learners from two high schools in the region. The researcher enlisted the services of the Subject Advisory to identify the best performing schools that practise Outcomes-based Education well. Teachers from the identified schools were interviewed to ascertain the assertion that theirs schools are best Outcomes-based Education practising schools, and one out of five schools was randomly selected. From the selected school two Grade 11 classes, one with 32 learners and the other with 29 learners, were assigned as experimental group. Furthermore, with the assistance of Subject Advisory, the researcher identified a school that taught in the traditional way, and again teachers from those schools were interviewed to establish the veracity of the assertion. From this school, two Grade 11 classes, one with 35 learners and the other with 26 learners, were assigned as the control group. For qualitative investigation, four learners who voluntarily accepted to be interviewed from the experimental group, together with their mathematics teacher were interviewed.

The study sought to provide answers to the following problem questions:

- What is the influence of an inductive teaching approach on the conceptualisation of functions in Grade 11?

- What is the influence of an inductive teaching approach on learning achievement with regard to functions in Grade 11?

Data collection and measuring instruments

Quantitative investigation: Self-constructed paper and pencil tests for learners on functions were used. The pre-test (Math Test 1) was based on the required entry competence of Grade 11 learners with regard to the function concept. The post-test (Math Test 2) was based on the work done during the intervention (Masebe, 2009). Items in the post-test were set and assessed according to O'Callaghan's four components of conceptualization of the function idea, namely modelling, translation, interpretation and reification. O'Callaghan's model was chosen because it provided an appropriate description of a function in terms of these four components. In this study a pragmatic evaluation in a form of pseudo experiment complemented with a qualitative investigation was used to establish that the use of inductive approach improved learners performance better than students using deductive approach.

Details of the questions for each of the four categories are summarized as follows:

(i) Modelling (Question 1): Notions of Hire Purchase plan and vending were used to show that word problems on these ideas could be expressed in mathematical statements of linear equations.

(ii) Interpretation (Question 2): A train pulling into a station does not come to an abrupt standstill. It decelerates over time until the final speed is zero. A linear graph with negative slope is used to show this decrease in speed over time.

(iii) Translation (Question 3): Depreciation in the value of a car is assumed linear in this component. A table of depreciation values over time in years are calculated in this question.

(iv) Reification (Question 4): Composition of functions concept is transformed into profit and sales in this component.

Semi-structured interviews were held with four learners and the teacher focusing on their views, experiences and preferences regarding the teaching approach and learning that took place in their respective classes. Learners were interviewed with the aim of reflecting on their experiences and perceptions of the teaching during the intervention period. Interviews were audio taped and typed verbatim. An independent observer was invited to ensure that the process has been successfully completed. Recorded tapes are in the possession of the researcher.

Data analysis
Quantitative analysis: Inferential statistics by means of t-tests, effect sizes and analysis of variance was used to analyse the experimental data (Leedy & Ormrod, 2005). The assistance of the Statistical Consultation Services of the NWU was sought.
Qualitative analysis: The researcher grouped information into segments that reflect various aspects of the experience. Divergent perspectives were identified. The researcher used various meanings identified to develop an overall description of the experience (Leedy & Ormrod, 2005). All data analysed and interpretations were subjected to literature control.

RESULTS

Interpretation Component
Analysis of quantitative data in interpretation component between groups for pre-test results
Table 2 below outlines information on the means of both the experimental and the control groups, p-value for both the experimental and the control groups, t statistic and the effect size and values for other variables for the translation component for both the experimental and the control groups in a pre-test as provided.

Table 2: T-test for groups for interpretation component (Pre-test)

Variable	Group1 = C (Control group) Group2 = E (Experimental group) T-test for Group							
	Mean:C	Std. Dv. C	N:C	t-value: C & E	P C & E	F-ratio Variances C & E	df C & E	P Variances C & E
Interpret Pre-testing	9.50	2.57	61	-0.45	0.27	1.33	120	0.01
	Mean:E	Std. Dv.E	N:E					
	9.70	2.23	61					

d = 0.08

The p-value of approximately 0.01 and the effect size of 0.08 indicate that there is a statistical significant difference but no practically significant difference. We conclude that the differences are not significant between the experimental group and the control with regard to interpret component.
Analysis of quantitative data in interpretation component within groups
We start first by providing analysis for the translation component within the control group. Table 3 below outlines information on the mean, p-value, t statistic and the effect size amongst others, for the 'interpretation' of pre-testing and post-testing.

Table 3: T-test for interpretation component (control group)

Variable	Group = C T-test for Dependent Samples Marked differences are significant at p < 0.05000							
	Mean	Std. Dev.	N	Diff	Std. Dv Diff	t	df	p
Interpret Post-testing	2.66	1.29	61	0.46	1.32	2.718	60	0.008
Interpret Pre-testing	2.19	1.18						

d = 0.36

The p-value is less than 0.05 and the effect size is 0.36. This indicates that the differences are significant.
We now look at the analysis of results of the 'interpretation' component within the experimental group. Table 4 below outlines information on the mean, p-value, t statistic and the effect size amongst others for the 'translation' component within the experimental group for pre-testing and post-testing.

Table 4: T-test for interpretation component (Experimental group)

Variable	Group = E T-test for Dependent Samples Marked differences are significant at p < 0.05000							
	Mean	Std. Dv.	N	Diff	Std. Dv Diff	t	df	p
Interpret Post-testing	3.09	2.20						
Interpret Pre-testing	1.68	1.63	61	1.41	2.74	4.01	60	0.0002

d = 0.64

The p-value < 0.05 and the effect size of 0.64 indicate that the differences are possibly practically significant.

Analysis of quantitative data in interpretation component between groups
Table 5 below outlines information on the means of the experimental group and the control group, and the effect size for the modelling component for post-test between the experimental group and the control groups as provided.

Table 5: Univariate Tests of significance for translation component (Post test)

Group;LS Means Current effect: F(1,119)= 2.5104, p = 0.11575 (Adjusted means)					
Group	Interpret Post: Mean	Interpret Post Std.Err	Interpret Post -95%	Interpret Post +95%	N
C	2.61	0.23	2.15	3.07	61
E	3.13	0.23	2.67	3.59	61

d = 0.29

From the effect size of 0.29, low F value and p > 0.05 we can conclude that the differences are insignificant.

Interviews held with learners

Question 1:   Can you tell any change that you noticed in the way mathematics was taught in your class since you took the pre-test?
Responses to the question revealed that learners indicated that the teacher introduced the lesson on functions, gave examples to clarify the topic and gave them time and space to go and explore more on the topic.
One of the learners said "The teacher introduced the new matter by teaching us, followed by several examples to clarify what she has been teaching. Examples are good because you can understand what is going on".
Two learners preferred that at the start of teaching the concept, a lot of examples be given so that they "understand better". According to them they understood much better if more examples were given, because they could not follow the lesson if they did not have ideas of what is going on.

Question 2:   Did you notice any difference in the way the teacher was teaching or was it just the same?

Responses to the second question indicated that two learners did not pick up any difference while others noted that there was indeed a difference in the teacher's approach to the topic. One learner said, "There was some difference because we were given a lot of examples on the topic and given research to do" and the other one said "There was not much difference to what we are used to, except that she would give us something to research after giving us several examples" .

Question 3: Do you like the way the teacher was teaching in the past three months or so?
There were mixed feelings to the teacher's new approach in response to the third question. Two learners were in favour of it, while other learners were not. This is what one said, "If the teacher continued teaching the way she did, I would benefit, but my peers complained that they could not do a thing without first being guided with examples,"

Question 4: Do you think that the way the teacher was teaching would make you improve your understanding or not?
There were also mixed feelings to the teacher's new approach in response to the fourth question. Two learners were in favour of it, while the other two were not. This is what one said "I do not like the way she was teaching, because if you do not know what is going on, you cannot do the research we are expected to do on the topic. I like it if she teaches"

Question 5: Did you like the way the teacher was teaching or would you prefer the way s/he was teaching before you took the test?
There were mixed feelings to the teacher's new approach in response to the fifth question. Two learners were in favour of it, while other learners were not. One learner said "I would like her to teach, because we do not understand that method, and there are no textbooks with answers to the projects we are supposed to do."

DISCUSSION AND CONCLUSION

Analysis of quantitative data revealed that the differences among components between the experimental group and the control group were generally significant. This was an indication of the success of the experiment, even though the total difference between the two groups in terms of performance was not significant. The performance between the experimental group and the control group was as good as equal. This may be attributed to some of the challenges highlighted by the teacher during the interview and that the experiment was carried out over a limited period of time.

Kieran (1992) identified that learners perceive functions as equations only, and cannot relate solutions of equations to values of corresponding functions in graphical solutions. This explains why learners understand functions from procedural rather than structural perspectives. Learners have a better conception of a function if it is in an equation form of computing one value of a variable based on another. Two learners felt that they needed to be taught first before they can work on exercises on function. The impression is that they find it challenging to transfer a word problem to a mathematical statement in symbols, and this is consistent with literature that learners find it difficult to transfer from graphical to algebraic and vice versa (Kieran, 1992).

Most algebra textbooks define a function as a relation between two sets so that one member of the domain has only one image. This emphasises the structural rather than the procedural view of functions and learners find it hard making sense of it because they are inclined to procedural conception of functions (Kieran, 1992).

Two of the learners interviewed hinted that without being taught first they cannot comprehend concept functions. The impression is that the teacher requested equations of lines, and they work out ordered pairs and translate the ordered pairs to Cartesian graphs.

41 - Assessing the Quality of Research: Development of a Framework

Ana Paula Cabral[1], Isabel Huet[2], and Lewis Elton[3]

Laboratório de Avaliação da Qualidade Educativa no Ensino Superior (LAQE/ES)
Centro de Investigação em Didáctica e Tecnologia Educativa na Formação de Formadores (CIDTFF) - Universidade de Aveiro
[1]apcabral@ua.pt

Abstract: The present paper aims to discuss a study based on the construction of an assessment framework for monitoring the quality of research in the University of Aveiro, with a special focus on education.

The main specific objectives associated with the study are to identify the key issues involved in research assessment (concepts, dimensions, models, criteria); compare international practices and experiences (review of the international practice); develop a set of contacts involved in the UK's experience to collect good practices and recommendations; design a general reference framework guidelines to evaluate the quality of research with a special focus on the educational research and develop a case study/ intervention at the University of Aveiro, Portugal. This evaluation approaches some of the concerns that the Portuguese research Centres/ Units and Laboratories have at the moment.

Keywords: Quality, Research, Assessment

INTRODUCTION

There is a vast literature on best-practice criteria for scientific assessment and research funding. In fact, this key issue for the enhancement of Science and knowledge is treated very differently in many countries and has been continuously discussed and amended in recent decades (OECD, 2003; European Science Foundation, 2003; European Commission, 2010a;). Changes in the research assessment practices are an important basis for the discussion of the challenges and responses of the science system, its structure, priorities and trends related to the allocation of funds, rankings, performance indicators, rating scales, and other topics focussing on competition, accountability, reputation and institutional performance (Wooding & Grant, 2003; OECD, 2002; European Commission, 2010c).

Putting the emphasis on the researchers' role, many studies address not only the questions associated with their profiles and motivations, career expectations, publication behaviours and incentives, but also the constraints that lead researchers across subjects and disciplines to publish and disseminate their work in different ways (Wooding & Grant, 2003; BERA, 2008; RIN & JISC, 2009; European Commission, 2010b). The literature has also contributed for a wide discussion about the assessment methodologies, namely; the panel selection criteria and peer review as well as the comparability of grades, the flexibility for assessors and the effort of research income and/or bibliometric analysis (Jenkins, 1995; Botte 2007; Brennan & Teichler, 2008; Brew & Lucas, 2009).

In the study field of the quality of research assessment, the oldest system from a scientifically advanced country is the United Kingdom. It started in 1986 with the Research Assessment Exercise (RAE) and has been evaluated and improved since then (Elton, 2002; HEFCE, 2003; Roberts, 2003; HEFCE, SFC, HEFCW, DELNI, 2008). More recently, many consultation periods and a wide discussion have been taking place around the new arrangements for the assessment and funding of research as embodied in the proposals for the Research Excellence Framework (REF) to be fully implemented by 2014 (Bekhradnia, 2009; Grant *et al.*, 2009; Adams & Gurney, 2010; HEFCE, 2010; Otley, 2010)).

Other international systems have, however, addressed the topic of quality of research in other ways according to their research funding policies and research priorities (e.g. Germany, Finland, Japan, United States, Norway, Australia) and many have published comparative studies that contribute for the discussion of good practices and recommendations (European Commission, 2010a; OECD, 2002; Grant *et al.*, 2009). In the Portuguese case, the *Funding Model and Assessment of the Research Units/Centers/ Associated Laboratories* developed by the *Fundação para a Ciência e Tecnologia* (FCT, 2004) is the reference document for a contextualized approach to the subject.

Overall, the dimensions of quality in such a specific area must acknowledge the importance of concepts such as: multidimensional and interdisciplinary dimensions, methodological and theoretical robustness, technological dimension, capacity building and value together with the economic dimension. Moreover, the

urge is to establish collaboration links between research and policy & practice, codification and communication of accredited knowledge to promote the engagement in a co-operative environment set on partnerships and programmes (Humes & Bryce, 2001; OECD, 2002; Pring, 2001).

All these topics have a special emphasis and relevance in what comes to Education, one of the most specific and challenging research fields. In fact, recent changes in the relationship between Education, Research and Society and the constant evolving role of research in knowledge production lead us the need to continuously discuss and adapt the concept of research quality in the educational field (Furlong & Oancea, 2005; McNay, 2003).

SCOPE AND OBJECTIVES

Based on an in-depth study concerning the organization of the research quality assessment systems, mainly in the European context, and in particular on the United Kingdom's system, this research aims to:

- *identify the main issues involved in research assessment*. The first approach is to analyze the views of research quality and attitudes towards different models of research assessment, concerning the major dimensions associated with the role of quality assurance and evaluation systems.

- *compare international practices and experiences*. Based on the understanding of the key concepts associated with Quality, Assessment/ Evaluation, Enhancement/Assurance, the focus is on the development of a review of the international practice (e.g. Germany, Finland, Japan, United States, Norway, Australia) in assessing research. The purpose is to collect experiences, proposals for a good scientific practice and measures to identify the impact and consequences of the research assessment model implementation. In a more detailed and contextualized approach to the United Kingdom's assessment system, the idea is to perform a study about its main characteristics and evolutions throughout the last twenty years in order to collect good practices and recommendations for the Portuguese context .

- *design general reference framework guidelines, based on the good practices and recommendations collected, to evaluate the quality of research with a special focus on the educational research.*

These guidelines are the basis for the creation of an assessment framework for monitoring the quality of research with a special focus on Education in the University of Aveiro. This project opens the possibility for the development of research projects in other scientific fields and using other methodological approaches.

RESEARCH DESIGN

The research design is based on a *two* step process closely interconnected: an exploratory/ diagnostic study and an assessment study.

In the diagnostic study the main aim is to perform a set of contacts with researchers, stakeholders and institutions involved in the UK's experience: Funding bodies (policy), institutions and researchers: Funding Bodies (Members of the UK's RAE panels - 2008); Institution Representative (leading research institutions and "New Universities"(post 1992) and Researchers (Experts in the area of Research Quality Assessment and researchers from the Educational field);

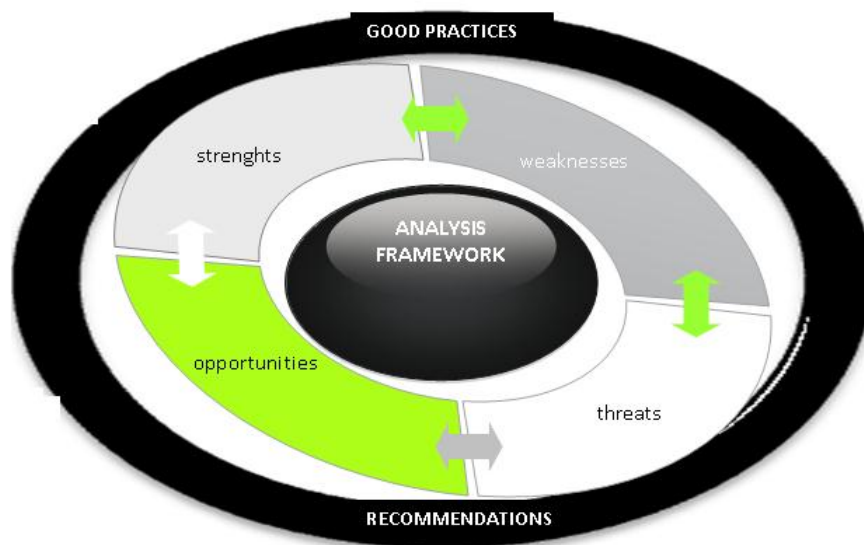
The main instruments for data collection are *semi-directed* interviews to funding bodies, research centres' representatives, quality assessment experts and researchers about their research quality assessment experiences, good practices and recommendations.
 In order to set the categories for the data analysis the interviews are structured in a SWOT – style adapted analysis framework (*Figure 1).*


Figure 1: Categories for data analysis

The good practices and recommendations collected allow the presentation of the main guidelines for a reference framework to evaluate the quality of research with a special focus on the educational field.

After this first diagnostic/ exploratory step, there is **an assessment study** based on the development of an internal approach about the research quality in the context of the Department of Education at the University of Aveiro, Portugal. This evaluation approaches some of the concerns that the Portuguese research Centres/ Units and Laboratories have at the moment.

The main aim is to collaborate with the institutional efforts to promote internal quality systems with a special focus on education. In fact, the specific scope of this research field has raised a wide internal discussion about how suitable/adapted the national system to assess the research developed in this area is.

This field work consists on the design/ adaptation of instruments (*surveys, focus group, interviews*) to determine how and why researchers communicate their knowledge, publish and disseminate their findings and perceive their role as education agents and researchers.

OUTCOMES

In terms of contributions to the construction of the framework we can already point out some indicators to be considered in the particular field of education. One aspect that stands out is the relevance of the use of strategies for peer assessment/review based on shared analysis of scientific production (outputs), based on criteria of rigor, relevance and efficiency.

In addition, we point out the need to implement internal measures to promote the quality of research *per se* irrespective of its approach, methodology or positioning. Moreover, given the nature of the scientific area in question, an aspect to consider should be applied and practice-based research itself that may take, especially the way in teaching / research / learning interact and share roles, particularly at the level of postgraduate training.

Another aspect to be integrated into a strategy of promoting quality is related to the development of internal mechanisms of circulation / information management related to scientific production of researchers and to access detailed information about projects in development at the institutional level as well as dissemination of opportunities for internal and / or external collaboration / partnerships.

In this sense, the collaboration between departmental areas of the same institution is a key factor for establishing intra / interdisciplinary partnerships between research groups and a networking tool for the development of research projects with international teams on issues and topics of common interest and interagency and international courses of advanced training.

Finally, we stress the relevance of the internal development of pro-active strategies to support researchers in areas such as scientific writing, methodological approaches, publication behaviours, *bibliometrics*, authorship, referencing, creativity, collaboration and internationalization seeking a common purpose – the promotion of high quality research.

67 - Traces of Europe: Whether the National Curriculum in Sweden Supports Teaching and Critical Discussion about European Identity

Laila Niklasson

Mälardalen University
laila.niklasson@mdh.se

Abstract: The paper present and discuss how the Swedish national curriculum is used during one work package in a European project. The European project PAM-INA (Perception, Attitude, Movement Identity Needs Action) aims at identifying perceptions/understandings, attitudes/attachments and ways of articulating/experiencing the idea of a European identity among its youth. Whether there is a written curriculum or not, what actually is used as directives in teaching can affect how a European identity is created. During the project school curricula for secondary school in eight countries were compared to examine how the idea of Europe is manifested and expressed. The results showed that the Swedish curriculum leaves much freedom to the students and the teachers to use instruction materials. The curriculum is over arching and contains mainly directives for values that should be given priority, like democracy. There are separate subject syllabi and the analysis showed that concepts like Europe, European citizen or similar were rarely mentioned. The result raises questions about teaching strategies towards a sustainable EU identity construction as well as a critical stance towards such an identity construction.

Keywords: Secondary School, Youth, Curriculum, Europe, Identity

INTRODUCTION

During the late 19th and early 20th century the concept nation became the framework for at least most European countries when the education system was created. In the late 20th century and the early 21st century the concept became more and more challenged and concepts such as international and global became just as important in the education system. Further on, regional concepts like Europe, has had an impact on how educational systems are created. Lastly, regional agreements like such as EU as an organization has had an effect. Even though education systems in countries in the EU are regarded as national, decisions and agreements on a European level have consequences for individuals, just as well as for countries. Also countries not belonging to EU can be affected of the EU decisions.

Those who are working in the education system on different levels also have to reflect upon different aspect of changes in the education systems. The education system is a framework where roles and identities are shaped in youth, but also in adult hood. In some countries in Europe there are possibilities to participate mostly in educational systems that have national directives; in other countries there are possibilities to have private companies with certain profiles in the schools, even though national directives can be overarching.

One way of responding to the challenge of changes on individual, group and system level in education is to be engaged in European projects. In 2009 an initiative was taken from Freiburg University and Ljubljana University to create a study. In total eight countries joined in: Freiburg University in Baden-Wurttemberg in Germany, University of Ljubljana in Slovenia, University of the Aegean in Greece, University of Lyon in France, Pedagogical University of Krakow in Poland, St Mary´s University College in Northern Ireland and Mälardalen University in Sweden. In 2010 the European Commission decided to fund the project called PAM-INA (Perception, Attitude, Movement, Identity Needs Action) aiming at identifying perceptions/understanding, attitudes/attachments and ways of articulating/experiencing European identity among youth in Europe. The project is a Comenius project in the Lifelong Learning Program and lasts between 2010-2012 (PAM-INA 2011)

This paper is about how a study was carried out aiming at identifying to what content on 'Europe', 'European dimension', 'European identity and citizenship' exists in Swedish secondary school curricula in social studies and how these are represented/constructed. Similar studies were carried out in the other seven countries and all national reports can be found on the PAM-INA website (PAM-INA, 2011). The results from the study in Sweden are presented, analyzed and then discussed.

BRIEF DESCRIPTION OF EDUCATIONAL SYSTEM IN SWEDEN

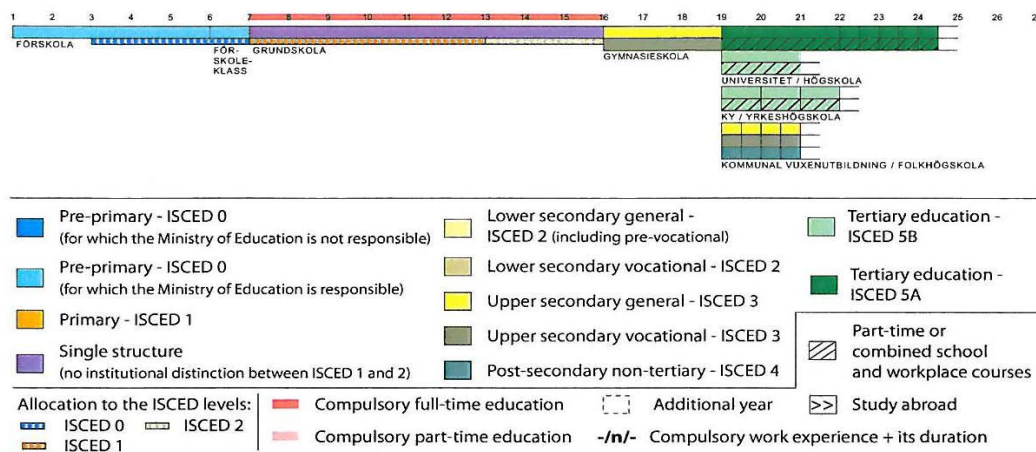
The population in Sweden consists of 9 million people. The national language is Swedish, but several other languages are spoken, partly because nearly one million of Sweden´s total population is immigrants or have at least one immigrant parent. (European Commission, 2010).

In Sweden, all children between the ages of 7-16 must attend school. The municipalities have to offer preschool, primary and lower secondary school and upper secondary school. The aim with compulsory school is to teach basic skills and knowledge that will be useful for further studies and when they act as a member of society (European Commission, 2010).

At age 16 (to age 20) the child can opt to continue to upper secondary school. Upper secondary include national programs and also specially designed programs. Some programs have a more vocational content, others are more theoretical. The aim is to offer a broad general education and prepare for studies at post-secondary level. (European Commission, 2010). Almost 1 000000 pupils attended upper secondary in 2008.

From age 18 young people can participate in higher vocational education. This education is designed in consultation with employers to meet manpower needs (European Commission, 2010). From age 18 young people can also study at folk high school. Otherwise they can study at different institutes, university colleges or universities.

As a summary, a presentation from European Commission (2010, p. 6) is shown below:

Figure 1: Presentation of the Education System in Sweden, European Commission, 2010


BRIEF INTRODUCTION TO THE OFFICIAL CURRICULUM IN SWEDEN

When the study was carried out Sweden had an educational system with a broad curriculum framework (läroplan) and syllabus (kursplan) for each subject or group of subjects. These directives were presented in separate documents. Both curricula for lower and upper secondary school had a part about values that was the same for lower secondary school and upper secondary school. Table 1 shows a simplified version of the system:

Table 1: Relation between curricula and syllabi in Sweden

Curricula for lower secondary school		Curricula for upper secondary school	
VALUES			
Syllabi for subjects		Syllabi for subjects	

As the study focus on the syllabi there is a need to present how it is designed. In lower secondary school there is a common text for the social sciences: civics, history, geography and history. In addition, there are four separate syllabi; one for each subject. In the common syllabus there is a description of the aim with the subject, goals to strive for, the character of social studies, goals to attain on different levels, and guidance for grading. The respective syllabus is designed in a similar way, the aim with the subject, goals to strive for, the character of the subject, goals to attain and directives for grading.

In upper secondary there are national program (17) and local programs. Some subjects are considered as core subjects. Civics and religion were considered as a core subject for all programs. The amount of time for

civics and religion depend on the chosen program, but the amount was at least one term. In the syllabus for Civics, as an example, there is a description of the aim with the subject, goals to aim for, the character of the subject, goals to attain and directive for grading.

METHOD
Sampling
As similar studies were carried out in eight countries several choices had to be made about how to carry out the data collection. First of all, national curricula/syllabi were chosen as representing political texts. But not all subjects were chosen; it was social studies such as

religion, history, geography and civics. The subjects were only relevant if they were compulsory on lower respectively upper secondary. This choice was made as the combination of social compulsory subject was assumed to give examples of creation of identity.

When the study was carried out a selection of document was made. The documents that were from Sweden used were:

Table 2: Documents used for analysis

Age group	Subject title	Title of Document	Pages	Published by
12-15 Lower secondary school	General	Curriculum for compulsory school	1-18	The Swedish National Agency for Education, 1994
12-15 7th-9th	Geography, religion, history and civics	Syllabi 2000, revised version 2008	1-101	The Swedish National Agency for Education, 2008
16-18 10th-12th	General	Curriculum for non compulsory school	1-19	The Swedish National Agency for Education, 1994
16-18 10th-12th	Civics A Religion A	Social Science Program Goal, Structure and Syllabi	17-21; 147	The Swedish National Agency for Education, 2000
	Civics A	Changes in the Syllabi and Grades for Civics at Upper Secondary and Adult Education	1-4	The Swedish National Agency for Education, 2008

RESULTS AND ANALYSES

Quantitative analysis of references to 'Europe'
A group of terms were decided to represent Europe, for example Europe, EU, and Council of Europe. Whenever the terms were used in the curricula/syllabi a mark was made.

In compulsory school the findings represent the entire compulsory school as it is not divided in the syllabi. Geography and history are taught in Grades 7-9, but only in certain programs in Grades10-12. The subjects Civics and Religion are core subjects that are compulsory. The syllabi for the subjects in upper secondary are divided in A, B, C level. It is Civic A and Religion A which are compulsory.

In summary, in secondary school it is in the syllabi for History where we can see one reference to Europe and one reference to European. In upper secondary it is in the syllabi for Civics that we find two references to EU:

Table 3: Overview of references to 'Europe' in the Social Studies Syllabi in Sweden

	Geography	History	Religion	Civics	**Total**
Europe	0	1	0	0	1
Eurasia	0	0	0	0	0
EU/EEC/EC	0	0	0	2	2
EU institutions	0	0	0	0	0
Council of Europe	0	0	0	0	0
Symbolic markers	0	0	0	0	0
Europeans	0	0	0	0	0
European identity/citizenship	0	0	0	0	0
European (adjective to noun)	0	1	0	0	1
European (individ. Countries)	0	0	0	0	0
Other	0	0	0	0	0
Total	0	2	0	2	**4**

The quantitative analysis indicated that a few references to terms attendant to 'Europe' occurred in the History documents and Civics documents. Comparing between them the terms in question, it can be noted that the references occurred in the categories 'EU', 'Europe' and 'Europeans'.

In Sweden there is a difference between the curricula and syllabi. Just as a comparison, let us study if the curricula for the compulsory school and the curricula for non compulsory school make any references according to our matrix:

Table 4: Analysis of curricula for Compulsory School and Non Compulsory School

Over arching curricula with common values for all subjects	Compulsory school	Non compulsory school	Total
European identity/ citizenship	0	1	1
Total	0	1	**1**

There were no references in the curricula for compulsory school to any of the concepts suggested in the matrix, but in the curricula for the non compulsory school one reference was made to European identity.

Representations of Europe

Secondly, different concepts were decided to use for analysis, such as if there were phrases referring to a spatial-locational entity, an economic entity, a political entity, a historical entity or a social-cultural entity. It is still the results which was already presented; four representations, which constitute the base for the analysis.

In the syllabi for History in Compulsory School there is one reference to 'Europe' and one to 'European'. In the common goals it says that "Essential parts of the subject are thus Swedish and Nordic culture, including Sami and European culture." In the goals for year 9 it says that the pupil should "be able to present important events and be familiar with the personalities, ideas and changes in the historical development of Sweden, the Nordic area and Europe, as well as be able to make comparisons with other countries.". This reference can also be perceived as a reference to Europe as a socio-cultural entity.

In the syllabi for Civics in Upper Secondary School there are two references to 'EU'. In the goals for the course it is described that the pupil should "have knowledge about the function of the political system on local, regional, national en EU-level" (my translation). It also states that the pupil "should understand how to influence political decisions on local, regional, and national level, within EU and internationally." (My translation).

Depending how the referred text above is interpreted the references can be regarded as spatial references to Europe and to an economic entity. When the Nordic area and Europe is mentioned in syllabi for History for Compulsory School, these concepts can be interpreted as spatial references. When EU is mentioned in syllabi for Civics for Upper Secondary School, the concept can be interpreted as an economic entity.

Constructions of European Identity and Citizenship

Lastly, an entirely qualitative analysis was carried out using questions of whether the texts defined or explained something about European citizen or European identity/citizenship. European citizenship was defined as denoting sharing legal-political institutions and values and European identity was defined as denoting ethno cultural characteristics or heritage.

How is then European identity and citizenship defined? The quantitative findings showed that there were four references to "Europe" in the syllabuses for compulsory school. Two of them, from the syllabi for History, could be referred to as regarding European identity. The syllabi for History has chosen culture as an essential part and it says in the syllabi "Essential parts of the subject are thus Swedish and Nordic culture, including Sami and European culture." (The Swedish National Agency, 2008, p. 69) Thereby it is implied that there is a European culture. Usually culture is looked upon as constructing identity so; also implied, European culture can be a pre requisite to a European identity. Further on it says in the syllabi that the pupil should "... be able to present important events and be familiar with the personalities, ideas and changes in the historical development of Sweden, the Nordic area and Europe, as well as be able to make comparisons with other countries." (p. 71). This also underlines both the possibility that there is a common history which can be perceived as a pre requisite for a European identity.

Two of the references are from the syllabi for Civics in upper secondary school. First it is described in the syllabi that the pupil should "have knowledge about the function of the political system on local, regional, national and EU-level" (SFS 2008:10, p. 3-4, my translation). It also states that the pupil "should understand how to influence political decisions on local, regional, and national level, within EU and internationally." (SFS 2008:10, p. 3-4, my translation). When the syllabi were written, in 2000, these criteria were not in the demands for different grades. They were amended in 2008.

If we distinguish between European identity and citizenship and define 'European identity' as the one which denotes ethno cultural characteristics or heritage (including blood bonds, culture, history, heroes, language, religion, customs) that are historically shared by a nation, then the syllabi for History supports creation of identity.

If we further on define 'European citizenship' as the one which denotes a sharing of legal-political institutions and values (e.g. common laws and constitution under a state, values of democracy, freedom, human rights, civil rights, political rights, etc) then the syllabi for Civics supports creation of a European citizen. In the syllabuses the references are not abundant, but the syllabuses have to be combined with plans on municipality level and on school level. The subjects are also influenced by the way the learning material is used, such as text books, websites, TV-programs.

If there are few references to Europe, Europeans and European culture, what are then references to in the overarching curricula? Let´s look at the curricula for the compulsory school. The first part is presenting the fundamental values of the school. It is stated that democracy forms the basis of the national school system (The Swedish National Agency, 2006a, p. 3 ff.). The concept democracy or democratic can be found continuously in the curricula, it is actually mentioned twelve times. Depending on whether democracy is perceived as a way of life or a political choice/system the concept then can be a reference to identity or citizen, maybe both. Also in relation to fundamental values in the curricula references are made to Christian tradition and Western humanism as fostering (p. 3). Instead of making references to the concept 'citizen', the concept 'member' is used in the text. When the task of the school is presented, the task is to promote the development of pupils into responsible persons and members of society (p. 5). The concept member is addressed, not the concept citizen in the overarching curricula for compulsory school.

Let´s continue with the curricula for the non compulsory school. Also here the fundamental values are presented. It is stated that democracy forms the national school system and that Christian tradition and Western humanism are values that foster (The Swedish National Agency, 2006b, p. 3). Compared to the curricula for the compulsory school, there is an addition. It says "The school shall contribute to people developing an identity which can be related to and encompass not just Swedish values but also those that are Nordic, European and global." (p. 4). This reference can be perceived as supporting a European identity. Just as in the curriculum for the compulsory school the concept 'citizen' is not mentioned. Instead the concept 'member' (of society) is mentioned in the overarching curricula for non compulsory school.

DISCUSSION

Europe is included, but in what way?

The aim of a part in the European project APM-INA was to identify whether references to 'Europe', and, if so how, what content they ascribed to representations of 'Europe' as well as a 'European identity and

citizenship' in the social studies secondary school curricula/syllabi in use in public secondary schools in some European countries. The results that were presented here are from Sweden.

The study showed that there were few references to words like 'Europe', 'European dimension' and 'European identity and citizenship' in the national syllabi for social studies in lower and upper secondary school in Sweden. References were although made, the syllabi in History mentioned 'European identity'and that the syllabi in Civic mentioned 'European citizen'.

Even few, the results can be discussed by help of researchers interested in the same area. During centuries Habermas has contributed to a discussion about the possibilities of citizenship and democratic society. Within the discussion about national, regional or global citizenship, he although discusses mostly a national or regional citizenship (Habermas, 1995, p. 271, 278-279; Habermas, 2001, p. 70f, 108f). But, as is seen when we used a definition from him, he made a division between social-cultural (identity) vs. legal-political citizenship (legal). The results showed that the words in the Swedish syllabi could be referred both to social-cultural identity and legal-political citizenship.

When Habermas discusses citizenship he also put deliberation on the agenda. This is an issue that several researchers in Sweden also have done. Englund (1988, 1996, 2000) have presented several critical analyses of how citizen education has been carried out and how dialogue between different groups can be supported, or not. One of his main results are how different agendas'play out when a curriculum is created. The citizen education is challenged by fostering for working life and transferring facts about subjects. For Englund citizen education is not mainly a national or regional (European) issue, but of discussing and practising democracy. The results from Englund´s research can be an explanation why the European identity has not become a priority in Swedish syllabi text; other identities, or rather roles, are also given priority (such as becoming employable).

Frimansson (2001) suggests a more firm approach. He promotes that compulsory school should include civics as it is the duty for the society to impart knowledge of what is ´good´. For Frimansson citizen education is about values. Value issues are also addressed by Afdal (2004). Afdal is discussing how citizen education and moral education is related. As I understand Afdal moral education and civic education are separated, which is not necessarily an advantage. Civic education and moral education can be perceived as a division between facts and values. Today a division between facts and values has led to a situation where civic education is not a critical force, according to Kemp (2004). In his vision a Citizen of the World, not of any state, is the best construction to aim for. As the curricula and the syllabi are separated in Sweden (until 2010, not after July 2011) we mainly find the global citizen and values in the curricula, not in the syllabi.

The dialogue in the class room can include preparation for activities as a citizen or not. Niklasson (2007) discuss where the active citizen can plan and organise civic activities, in the class room or outside the class room, also from a European perspective. In a more practical manner, authors from the Erasmus Academic Network, Children´s Identity Citizenship in Europe (CiCe, 2011) have carried out studies and also constructed material for education about citizenship. Regarding Sweden the results in the study shows that the interest for citizen education is on three levels, national, European and Global. The network is also not exclusively discussing a European level; it also includes a global level and what they call a local level (Cappelle, Crippin and Lundgren 2010). The authors define global education as putting emphasis on providing students with information (my emphasis) about such issues as human rights, the environmental, sustainable development, peace, the multicultural nature of our world, the costs and benefits of economic development, the impact of technology, etc. (p. 3). World citizenship education does not concern collecting information but to start a critical analysis about what can be done and what should be done, thereby being more action oriented (my emphasis). When Sweden is presented by the authors (p. 11) they also come to the conclusion that it is a global citizen, rather than a European that is supported.

On the other hand, even though researchers in Sweden have been mainly concerned with international issues, such as Human rights, we can see a significant difference in how the course plans are formulated. As the course plans are very short, it is important to notice that Europe is mentioned. This change was made just a few years ago. Further on, the course plan is an over arching document, we have not studied all the teaching material that is used for teaching and learning. As the teachers and pupils in Sweden have freedom to choose how to reach the goals, there can be a lot of texts about Europe, or almost none.

What there cannot be is an absence of Europe that is clearly underlined in some of the course plans. In other words it can be interpreted as the syllabi are focused on describing the content of the subject. This description is overarching. What is actually carried out in teaching and learning is a question that is negotiated in the actual situation in the learning environment. That is, the teachers have a responsibility and a possibility to (in co operation with other stakeholders…) to decide not whether, but how much, room the question of identity, and European identity, shall be addressed.

European projects and identity formation

When studies are carried about concerning education systems and especially curricula in eight European countries, selection and choices has to be made. Soon it became obvious that a presentation of each countries education system would be necessary. Further on we noted that the curricula design varied. As a consequence the final design of this study suits certain education systems more than others.

There was a division between curricula and syllabi in Sweden and to handle that a section is written also about how the curricula is overarching (with values) and the (subject) syllabi are separate. On the other hand, even when the curricula were included in the study, not many sign of Europe could be seen. This is due to another difference between the countries. In Sweden the syllabi is very concentrated. In other countries the syllabi (or rather curricula as it seems to be more common to integrate them) are more elaborated. The consequence is that in Sweden teachers (and pupils) have several choices to make when the studies are carried out. On the other hand, when a syllabus is very concentrated, every extra word is important. In this case Europe and EU has been completed in the texts and that is a clear directive to the teachers and pupils, a European 'dimension' has to be included.

A key limitation of this study and similar ones was that it focused on official curricula at one level of education (secondary) and in specific subject areas (History, Geography, Economics, Religious Studies, Civics). If the study would have included language there would have been more references to identity as identity is interpreted as developed in combination with language in a Swedish context.

But the above mentioned aspects are mainly concerning a quantitative aspect. The qualitative analysis with the difference between socio-cultural and legally-political identity formation (maybe role formation) is fruitful, just as well as the analysis using spatial-locational entity, an economic entity, a political entity, a historical entity or a social-cultural entity.

In summary, co operation in European projects can results in fruitful descriptions, analysis and discussions about European dimensions in education systems and identity formation. But it can be noteworthy that there are differences among countries and it can be wise to give room for country specific discussions of how projects are perceived and handled.

CONCLUSION

Within a framework of a European project it was possible to critically discuss the relation between school syllabi and identity formation among youth, especially a European identity. The results from Sweden show that the syllabi give directives that a European 'dimension' should be in the content in social studies. As the directives are overarching, what is actually carried out in the classroom is a question for the actual situation.

72 - Conceptions of Portuguese Primary School Teachers about Science Education: Their Relevance in Innovative Classroom Activities

Conceição Costa[172] and Isabel P. Martins[2]

Centro de Investigação Didáctica e Tecnologia na Formação de Formadores (CIDTFF) Universidade de Aveiro (PORTUGAL)
[1]conceicao.costa@ua.pt,[2] imartins@ua.pt

Abstract: Multiple as they may be, all programs designed to promote Scientific Literacy (SL) with an Education for Sustainable Development (ESD) referential and according to Science / Technology / Society (STS) guidelines, include the intention to develop learning and teaching practices that are both innovative and appropriate for contemporary demands. According to several authors, teachers play a decisive role in the quality of education, in the development of favorable attitudes towards the learning of science and in the implementation of curricular reforms. They also agree that the interpretation teachers make of the programs determines their classroom activitie
s and stems from their own conceptions about science education. Therefore, understanding the conceptions teachers form regarding science education can influence and improve teaching practices and the potential success of educational reforms.
We present Portuguese primary school teachers conceptions about science education (obtained during semi-structured interviews) and in relation to: relevance; ESD; SL; STS guidelines.

Keywords: conceptions about science education; Education for Sustainable Development, innovative practical teaching

INTRODUCTION

The declaration of the Decade of Education for Sustainable Development (2005-2014) gives an important role to education in general, and to science education in particular, in helping solve the situation of planetary emergency humanity currently faces. In Education for Sustainable Development (ESD), Scientific Literacy (SL) was established as one of the contributions that stimulate the understanding of current issues and problems so responsible decisions, justified as they may be in the present, will not compromise the future.

It is not easy to explain how formal teaching and learning of science in primary years of schooling can help develop skills where actions can be justified and do not compromise the future of our democratic society, marked by the prevalence of developments in science and technology, occurring at a fast pace, with implications for personal life, society and the planet.

Achieving these goals requires change in several areas: curriculum; assessment; didactic resources; initial and ongoing training of teachers. With this in mind, we state a view of an SL interpretation transposed into a program, contained in the curriculum, whose design is framed with an ESD referential and Science / Technology / Society (STS) guidelines.

According to several authors (Abell, 2007; Nóvoa, 2007; Osborne, Simon & Collins, 2003; Tobin & McRobbie, 1996, between others) teachers interpret programs according to their conceptions about science education and that interpretation determines their classroom activities. They also contend that, in order to change their practices, teachers should understand their own conceptions about science education and the relationships established between thought and action.

Predisposal to change the methods applied in the classrooms is equally necessary, allowing for a free discussion of problems stemming from the implementation of activities that are not included in their usual repertoire.

Understanding conceptions of the teachers about science education can therefore help us promote mechanisms that will permit an innovative programme implementation in the classrooms.

In Portugal compulsive school includes first Cycle Primary School (1st CEB) for children between 6 and 10 years old: 1st, 2nd, 3rd and 4th school years.

Results of international studies show that Portuguese students have, on average, a performance in the field of scientific literacy significantly below the average of OECD countries (OECD, 2010). Some studies have shown that the practices of science teaching in Portuguese schools are still incomplete, both in working methods, both in time that is allocated to (DGIDC, 2011). Recognizing that the experimental teaching of sciences in the primary years of schooling can contribute decisively to the promotion of SL, the generalization of experimental science teaching in primary education, with appropriate evaluation, constitute a priority objective of educational policy in XVII Constitutional Government.

So, the Portuguese Ministry of Education made "...*experimental science education 2,5 hours a week...*" compulsory and created in conjunction with the Higher Education Institutions and 1st CEB schools, the 1st CEB Teacher Training Program for the experimental teaching of science. This program, nationwide, non-compulsory, involved an in-service training of 63 hours (which included 9 hours classroom monitoring) over an academic year (in Portugal, the school provides the beginning and end of the academic year in September and July respectively, with teaching interruptions at Christmas, Carnival and Easter). The programme also provided the laboratory equipment necessary to conduct the activities listed in the experimental training program to the schools of teachers who voluntarily attended.

The authors of the 1st CEB Teacher Training Program for the experimental teaching of science, which took place over four years (2006-2010), developed and provided educational resources for Teacher Trainers and 1st CEB teachers.

Based on the analysis of the discourse these teachers offer we present conceptions of 1st CEB teachers about science education (obtained during semi-structured interviews) and in relation to: i) its relevance; ii) SL; iii) ESD; iv) STS guidelines.

The selected teachers were involved and devoted to their practices, and their skills were approved by peers.

THEORETICAL BACKGROUND

Several problems connected to the teaching of science can explain the lack of interest for this area and the selection of different academic and professional trajectories, as well as poor student results. Osborne and Dilon (2008) state that the European Union "should invest significantly in research and development in assessment in science education. The aim should be to develop items and methods that assess the skills, knowledge and competencies expected of a scientifically literate citizen" (Osborne & Dillon, 2008, p. 9). The European Commission mentions the unsettling decrease of the interest youth develops towards science, which holds serious repercussions for European development and progress: "the long term capacity for innovation that Europe holds and the quality of its research will also decline. Furthermore, among the population in general, the acquisition of skills that are becoming essential in all walks of life, in a society increasingly dependent on the use of knowledge, is also under increasing threat" (p.2). Attaining such goals calls for change in several domains: curricular, evaluation, resources, initial and ongoing teacher training. We selected the program, as part of the curriculum, because we consider it to be fundamental as a basal structure in the process of teaching and learning. Multiple as they may be, all proposals for a program conception oriented towards the promotion of sustainability include the development of SL and the intention of developing ground-breaking practices for the teaching and learning of sciences addressing current demands, since according to several studies children are predisposed to learn science from an early age (Martins *et al*, 2006).

According to UNESCO guidelines, ESD must detain a high quality, be holistic and oriented by democratic values and principles, aiming for the promotion of a responsible citizenship, aware of the planetary emergency situation we currently face, respecting the limits of our Planet and taking responsibility for all living beings. In that sense, it must consider the complexity of interactions established between the environment, society and economy, all of them essential to sustainability. ESD should be considered at all times in science education: in content selection (multi, trans and inter disciplinary); in context selection for emerging concepts; in classroom strategy/activity selection; in scientific and technological comprehension of problems and their impact in the social, environmental, economic and ethical order; in developing certain skills, aptitudes and values (respect, cooperation, solidarity); in reinforcing democratic values and processes of participation (questioning, debating ideas, managing conflicts, voting, dialoging, reaching consensus).

Different SL conceptualization proposals suggest several implications for the formal teaching and learning of science, concerning the knowledge and the skills that promote an active participation in democratic societies, where the increase of scientific and technological developments, as well as their consequences, requires informed interventions that must not compromise the future (DeBoer, 2000; Praia, 2006). It is not easy to

identify a particular set of knowledge and skills that allows us to proclaim that a certain individual is scientifically literate. Considering the complexity of the concept itself, it is not easy to say "what does holding SL mean?" The SL concept is evolutional (considering it depends on social and economic contexts in each particular period of time), extremely broad, historically held and still holds several meanings (Martins, 2004).

By defining SL dimension we intend to designate the set of (re)conceptualizations we consider students should have when concluding their primary school years, in order to develop widely varied skills, aptitudes, attitudes and values that will allow them to live and adequately intervene in a democratic society and to adapt themselves to its vertiginous development rhythm, to the implications of this in their lives, in society and in the planet. This attitude should also allow them to continue their studies in science and stimulate them to continue its learning process all throughout their lives.

Despite the debate and controversy concerning what really is evaluated with the PISA tests, their results assume great relevance in our days and the issues they evaluate are consistent with the goals of science programs developed for primary school years and promoting SL. In this study we assume the definition of PISA for SL: "the capacity to use scientific knowledge, to identify questions and to draw evidence - based conclusions in order to understand and help make decisions about the natural world and human interactions with it" (OECD, 2010). The evaluation performed by these PISA tests falls upon: "Knowledge", "Skills" and "Attitudes", perceived as: i) "Knowledge – understanding the natural world based in scientific knowledge, including both the knowledge of the natural world and the knowledge concerning science itself"; ii) "Skills – includes identifying scientific questions, scientifically explaining phenomena and drawing conclusions based on data"; iii) "Attitudes – reveal interest in science, support scientific investigation and show motivation to act responsibly when dealing with, for instance, natural resources and the environment."

We can globally describe the world in which we live by the interconnections established between the broad range of scientific and technological knowledge, mainly developed from the latter half of the 20th century onwards, and all political, economic, social and environmental changes these interconnections imply. STS guidelines for science education reflect a dialog between different scientific fields, namely between natural sciences and social and human sciences, they highlight the social significance of the knowledge set forth by science and technology which, at the same time, provides a better understanding of the natural world and represents an essential instrument for its transformation (Cachapuz et al, 2008). Guiding the education of science with a humanistic, global and less fragmented point of view, and also potentially preparing students to better understand the World and the interconnections between scientific and technological knowledge in society, has become an asset for the teaching and learning of science (Aikenhead, 2009). Studies carried out in different countries in order to understand the impact of STS guidelines in teaching revealed a common attitude improvement from the students towards science, and showed that the comprehension of scientific ideas development is equivalent to the one observed in traditional approaches (Bennett et al, 2006).

A growing body of research suggests that the conceptions teachers form affect their teaching practices, their classroom judgments and classroom management (Lim & Torr, 2007; Thompson, 1992, Van Driel, Bulte, & Verloop, 2008). A better understanding of the educational conceptions held by teachers is therefore essential in order to influence and improve teaching practices and to guarantee the success of educational reforms. Given the importance of an innovative program in the development of this research, we tried to understand conceptions of Portuguese 1st CEB teachers about science education in relation to the importance they perceive in science education and in the structural dimensions of the program: ESD; SL; STS guidelines for science education in early years.

There is no consensual opinion among scholars concerning the definition of teaching conception (Richardson, 1996). The first studies were published in English during the first years of the 20th century (Thompson, 1992) and they applied the same meaning to "conception", "belief" and "knowledge". For a long time, despite this conceptual confusion, researchers have tried to clarify their terminological discussion concerning the beliefs of teachers and to define profiles in these beliefs. In this current study we assume the teaching conception that Thompson (1992) defines as: "a wider mental structure that includes beliefs, meanings, concepts, propositions, rules and mental images", (p.30).

METHODOLOGY

The methodology applied in this empirical study followed a qualitative approach that allowed us to understand conceptions of Portuguese 1st CEB teachers about science education. We chose a semi-structured interview to collect data that allows us to understand: a) the importance they perceive in science education and in the experimental science teaching component; b) how they believe science education can contribute to EDS; c) what subjects they relate to the EDS concept and how are those subjects approached in the

classroom; d) how they perceive SL, how significant they believe developing SL skills is and what strategies they apply in the classroom in order to achieve it; e) what SL skills they consider a student should have developed when concluding primary school, considering EDS; f) how they perceive STS guidelines for science education and how they are applied in the classroom.

We interviewed 19 experienced 1st CEB teachers, whose value is recognized by their peers (as involved and devoted to their practices), teaching in Portugal during 2010/11.

The results were obtained using the content analysis of interviews. According to Bardin (1997) it intends to "overcome uncertainties" and "enrich its reading" (p.29).

RESULTS
We now present the obtained results, according to each item approached during the interview.

Importance perceived in science education and its experimental component

All interviewed teachers believe it is very important to teach science in primary school years (from 6 years of age), pointing out some of the following reasons (in order of frequency): it is interesting for the children; it satisfies the curiosity of children; it is ever-present in our current lives; it helps children to understand/interpret daily phenomena (or what they see on the TV and in the Internet); it teaches children to think; it enhances interdisciplinarity.

All teachers mentioned that the reason why after September 2006, "*...experimental science education 2,5 hours a week...*" becomes compulsory, was the need to fight a general tendency to perform very few "experiments", and only in the end of the school-year (as proposed in school manuals).

Some of the experimental activities performed prior to 2006 and mentioned by the teachers included seed germination and floating solids in liquid media. The most frequently referred methods for those "experiments" were: i) concerning germination: wrapping the seed in moist cotton, placing it in a glass container, exposed to light, and "watering" and "observing" it; ii)) concerning floating: several objects were placed in a bowl of water and students "had to say if they floated or not". Less frequently, they also mentioned changes in physical states (interpreting window "misting" during winter) and solutions (students verified that sugar and salt "disappear" when mixed with water).

Although they recognize the interest of experimental activities for their students, allowing them to develop transversal skills related to reading, writing, communicating and calculating (and despite being compulsory) they admitted they did not always perform 2,5 hours of experimental activities per week, stating: it is more important to teach them how to write, read and calculate; the current program does not offer guidelines for experimental activities that fulfill the established educational component; they do not feel sufficiently prepared to perform experimental activities; there is no equipment in schools.

Teachers attaining the 1st CEB Teacher Training Program for the experimental teaching of science reported: they feel better prepared to perform experimental activities with their students; they perform more experimental activities; the importance of the laboratorial equipment supplied to the school by this program.

Science education contributes to EDS

All teachers believe that science education can contribute to EDS, as long as "children are alerted to the importance of adopting behaviors that will not compromise the future of our Planet". According to most of them, developing suitable attitudes and behaviors from an early age allows them to grow into "responsible adults".

EDS related subjects and how they are taught in the classroom

The subjects most frequently identified by teachers are: pollution; water and energy scarcity; biodiversity loss ("taking care of animals and plants" to avoid their extinction); and resource finitude. Less frequently they also mentioned local asymmetries (concerning in particular hunger and poverty) and respect for "different" children.

They all think these subjects should be taught in the classroom for every 1st CEB years, and they mention a teacher-moderated debate as the privileged strategy. Involving children in research and field trips, as well as inviting specialists to classroom debates, were also mentioned.

Generally speaking, subjects are brought to the table by students themselves (because they heard about it on the TV news or read about in the Internet), or they result from reading texts proposed by the teacher in Portuguese language classes. However, the celebration of water, alimentation and environment days and the international forest protection year are considered privileged moments to teach subjects related to them, and they are implemented in the *Project Area*.

<u>SL conceptualization, the importance perceived in developing SL skills and preferred classroom strategies</u>

Most teachers think that an SL holder is someone with a "great scientific and technological knowledge". This knowledge was less frequently associated with a responsible citizenship and with the implications of our actions for our Planet, ourselves and others.

All teachers believe that formal education should include the development of SL skills during all 1st CEB school years, and teacher-moderated classroom debates are considered the most promising strategy for any school year. Concerning 3rd and 4th grade children they also include: researching and preparing a presentation for the class; "experimenting"; making flyers and posters. Some of the strategies these teachers mentioned for the development of SL skills include: involving students in the separation of trash for recycling in school (and asking them to do the same at home), giving them guidelines to save water and electric energy, and studying behavioral changes in them through dialogue. Choosing an adequate diet, in an individual health perspective, and involving children in solidarity campaigns (collecting toys and clothes for children in need) were also mentioned. They all believe children play a significant role in influencing their parents to adopt the same behaviors.

All teachers believe that the benefits of scientific and technological development outweigh the setbacks. They most frequently pointed out developments that helped solving environmental issues and led to health and lifestyle improvements as positive aspects. The majority of the participants believe that science and technology only can help us solve the problems we currently face. All of them think it is important to debate both the advantages and disadvantages of such developments.

All teachers blamed the Human Being for the problems we currently face. They most frequently referred to the bad use we make of scientific and technological developments, based on a "poor knowledge or a lack of civism". They all consider the importance of debating positive and negative aspects of scientific and technological developments with their students.

<u>SL skills that a student should have developed when concluding primary school and according to an EDS referential</u>

Almost all teachers contended that students should "be able to make decisions in order to preserve the environment".

<u>STS guidelines for science education and classroom experiments</u>

Only one teacher revealed that his activities "involve science-society-technology interaction and intend to form responsible, critic and active citizens". All other teachers had no knowledge of the STS guidelines for science education, or they knew they existed but did not know what they were exactly.

CONCLUSIONS

The teachers who participated in this empirical study believe that science education is very important during primary school years. Notwithstanding, teaching the Portuguese language and Mathematics is considered more important.

Generally speaking, teachers assign some EDS related subjects to their students and reveal some concern with the development of SL skills. However, no intentional and systematic connections are established between those subjects, resulting in occasional and fragmented approaches. The conceptions these teachers hold of EDS and SL are practical directions.

Concerning EDS, all subjects considered the most relevant by these teachers are essentially environmental (general pollution, water and energy scarcity, and resource finitude). Social and economic components are barely mentioned, and no connections whatsoever are established between all these subjects. There is also no mention of demographic growth and its concomitant demographic pressure or current consumerism levels and respective impacts. Respecting and protecting biodiversity (although theses terms are not applied) are assigned to the students so they can learn how to accept "different" children and "take care of animals and plants", respectively.

Subjects that deal with the impact of science and technology are also assigned to students, frequently related to school and domestic environments and to the comfort they bring to our daily lives. General pollution and environmental degradation are often mentions as its setbacks. They do not mention any influence of science and technology in the increase or decrease of asymmetries and they also do not highlight their importance in identifying and predicting problems.

In short, we can conclude that teachers who participated in this empirical study perceive little value in science education, they recognize scientific and technological knowledge for its intrinsic value but they do not establish any intentional connections between that conceptual body and the development of SL skills.

Similarly, ESD constitutes an occasional and unintentional reference, and teachers do not establish any connections between ESD and scientific and technological knowledge (re)conceptualizations or the development of SL skills. Almost every subject assigned to students and considered relevant relates to that region, to the country and to the environment.

These teachers apply teaching and learning methodologies that do not follow STS guidelines for science education.

The conceptions we found among the teachers who participated in this empirical study, concerning the dimensions of the analysis that we previously defined (the importance they give to science education, ESD, SL and STS guidelines for science education) drew back the emergence of innovative classroom activities.

140 - Challenges of the Studies 'State of the Art': Research Strategies in Post-Graduation

Adriana Claudia Martins Fighera¹, Ana Carla Hollweg Powaczu2¹, Doris Pires Vargas Bolzan[3], Eliane Galvão dos Santos[4], and Gislaine Aparecida Rodrigues da Silva Rossetto[5]

Federal University of Santa Maria, Brazil, Post-Graduation Program in Education
[1]teacheradrianacm@hotmail.com, [2]anapowaczuk@hotmail.com, [3]dbolzan19@gmail.com, [4]eligsantos@yahoo.com.br, [5]gislainesilvarossetto@gmail.com

Abstract: The studies of state of the art allow systematizing a determined area of knowledge, mapping and acknowledging the productions, identifying dominant and emerging themes and approaches, as well as gaps and unexplored fields opened to research, in a temporal and definite frame. This article presents the directions chosen by the authors in the production of state of the art in each of the themes to be developed in their Ph.D. theses. This research is a result of the authors' reflections – Ph.D. students of the Post-Graduation Program in Education at Universidade Federal de Santa Maria (UFSM), Rio Grande do Sul, Brazil – while producing their studies of the type state of the art. With the results we have discussed the different strategies adopted, the possibilities and challenges of this type of study, focusing on aspects such as the delimitation of a view face to the large number of works conducted and published, the establishment of targets and categories of analysis, the relativity and the incompleteness inherent to research of this type.

Keywords: state of the art, research strategies, researchers' formation.

INTRODUCTION

Works in the area of Education which deal with 'State of the Art' have been considered focus of attention for different researchers (André et al., 1999; Brzezinski & Garrido, 2001) and institutions which promote research. Such an undertaking signals efforts towards understanding how academic scientific works have been produced. It is understood that the advances in production of knowledge necessarily entail this process, as they allow the researchers to know about what is being produced along time.

According to Romanowski and Ens (2006) the interest for research which deal with 'state of the art' stems from the range of these studies in pointing ways which have been followed and aspects which are approached in detriment of others. The realization of these balances makes it possible to contribute with the organization and analysis in order to define a field, an area, besides indicating the potential contributions of the research. The investigative analysis is essential in a time of intense changes associated to the increasing advances in science and technology.

The study of state of the art consists of an important step for the development of any type of investigation. However, this process has revealed extremely complex, given the great amount of works currently produced and published, through several different sources, forms of communication and sharing of research results.

In this perspective, the production of this study raises countless questions: how to circumscribe studies which deal with a specific issue? What search strategies are possible to be used? How to validate the study developed? Is it necessary to consider the totality of productions about the investigated issue? These questions, necessary for the contextualization of the themes involved in the individual research projects, were part of the authors' reflections, Ph.D. students of the Post-Graduation Program in Education at Universidade Federal de Santa Maria (UFSM)[173], while developing their studies regarding state of the art.

We understand as state of the art a mapping which allows a broader view on the issue we intend to research, better situating ourselves on the progress in research in the field studied, revealing the most frequent concepts, as well as those in which there are not further studies. According to Messina (1998):

> A state of the art is a map which allows us to continue the journey; it is also a possibility of perceiving speeches which at first sight present themselves as discontinuous or contradictory. In a

---

[173] Public Institution of Higher Education located in Santa Maria, Rio Grande do Sul, Brazil.

study of the art there is the possibility of contributing with the theory and the practice in a field of knowledge (p. 1) [174]

In agreement with the definition of this same author, we highlight that the possibility of contributing with theory and practice of a field of knowledge can occur at different levels of detail and depth of investigation, depending on the focus it has.

It is possible to develop the study of state of the art with the purpose of making a review of the scientific literature concerning a given subject in order to support the development of a research. In this course, the final objective is to obtain a general panorama of the knowledge developed in a field, area, issue, authorship and specific concepts, and identify possible gaps in respect to works which were not developed or which are recurrent and consolidated issues. It is possible to say that it characterizes the first level of elaboration of a study on state of the art.

Another way of constituting state of the art, which frequently follows the first level, is to know the detailed studies while establishing criteria of analysis of each complete work. These levels of study for the production of state of the art are characterized by being descriptive and analytical.

CONTEXT OF INVESTIGATIONS

The studies on state of the art which were realized are linked to the project *Learning teaching and formation processes: constructive movements of professorality in basic and higher education* (*Aprendizagem docente e processos formativos: movimentos construtivos da professoralidade na educação básica e superior*), developed by the study group Studies and Research in Teacher Formation and Educational Practices/Basic and Higher Education (Estudos e Pesquisas em Formação de Professores e Práticas Educativas/Ensino Básico e Superior – GPFOPE), registered at CNPq[175] since 2002, with research supported by CNPq, FAPERGS[176] and UFSM. The group leader is Professor Dr. Doris Pires Vargas Bolzan and vice-leader is Professor Dr. Silvia Maria de Aguiar Isaia.

The central focus of the cited project is the learning of teaching and the formation processes of higher education teachers, subdivided in themes which deal with: movements in the formation of higher education teachers in Foreign Language Degree (Fighera, 2010); constructive movements of university *professorality* (Powaczuk, 2008); extension activities in Institutions of Higher Education, formation processes which result from these themes (Santos, 2009); and construction of teachers' intellectual autonomy (Rossetto, 2009). These investigative themes consist of projects for individual theses advised by GPFOPE's leader.

In this perspective, this article presents the directions taken by the authors during the production of state of the art in each of the issues to be developed in their Ph.D. theses. And it also discusses, from the different directions, the adopted strategies; possibilities and challenges which circumscribe the production of this type of study, highlighting the delimitation of the perception face to the great number of works produced and published; the establishment of goals and categories of analysis; and the relativity and incompleteness inherent to researches of this type.

DIRECTIONS FOLLOWED IN THE REALIZATION OF STATE OF THE ART CONCERNING THE THEMES

Encouraged and moved by the challenge of mapping what has already been produced and the gaps still remaining in the field of knowledge which each author intended to research, we have followed different ways in the elaboration of the study of state of the art. In this process, we have elected distinct procedures for research: definition of sites and periods of patrimony considering their relevance and references for the scientific production in the field of education, selection of search descriptors, organization of criteria for the composition of components of state of the art, definition of axes of analysis and patterns of record according to the needs of the individual research. The peculiarity of this work consisted of sharing the challenges which

---

[174] Authors' version.

[175] Founded in1951 and until 1971 held the name National Research Council (Conselho Nacional de Pesquisa – CNPq), after this date its designation has become National Council of Technological and Scientific Development (Conselho Nacional de Desenvolvimento Científico e Tecnológico), however, the initial abbreviation has been kept. It is an organization which promotes researches in Brazil and is linked to Science and Technology Ministry (MCT) of the Federal Government and, also, aims at contributing with the formulation of the national policies for science and technology.

[176] Fundação de Amparo à Pesquisa do Estado do Rio Grande do Sul (FAPERGS) is an organization which promotes research at state level founded in 1964, aiming at developing research in all areas of scientific and technological knowledge in Rio Grande do Sul.

each researcher found along the production of their study, as well as the divulgation of search strategies used and the verification that the four works presented lead to a procedure of analysis of materials which indicate recurrences in the analysis system.

1st Research: Study on Higher Education and Teacher Formation in Foreign Language Degrees

This study of the art has aimed at enlarging the possibility of approximation with the reality in research production in Higher Education regarding the issue teacher formation in English Language Teaching Degrees. The definition of the steps for data collection, to say, the selection of materials to be analyzed, has proved a very complex process. The reading of some works with similar objectives (Ferreira, 2002; Romanowski e ENS, 2006) corroborated with the understanding of important aspects on the realization of this type of study. These authors highlight that the analysis of the summaries alone is not sufficient as a component for a state of the art. This has become an obstacle along the development of the study because it is not always possible to find complete publications.

The work's starting point was the curriculum *Lattes* of the researchers in this area, research group coordinators, such as the ones at Universidade Federal de Minas Gerais (UFMG), Universidade Federal do Rio Grande do Sul (UFRGS) and Universidade Estadual de Londrina (UEL), Paraná. There was an attempt to answer what aspects and dimensions are highlighted and privileged in studies of teacher formation in Degrees of English Language (EL). Also, the objective was to promote discussion concerning research on the teaching construction in Higher Education institutions.

This work refers to academic production in Post-Graduation Programs in Education, expressed in Ph.D. theses and Master's dissertations, read in full. Among the analyzed dissertations and theses in this state of the art regarding teacher formation, defended in the last five years, it was conventionalized to classify those which dealt more specifically with issues related to teacher formation for teachers in the English Language Degree. The research widens as theses and dissertations elaborated in Post-Graduation Programs in Linguistics have also been considered material for data collection.

Works presented at ANPEd[177] meetings – from 2005 to 2010 in GT4-Didactics and GT8-Teacher Formation groups – and at ENDIPE[178], 2010, were incorporated to the *corpus* analysis for the development of this study. Conference proceedings in Language Degrees – such as APLISC Annual Meeting (Association of English Teachers of Santa Catarina, SC, Brazil) and the International Congress ALAB (Brazilian Applied Linguistics Association) – of the last five years, have also been regarded as relevant. In the light of these choices of sites and time, the data collection has been developed since the title and abstract of a work until its complete reading, when available.

Thus, three theses and six dissertations were selected; two works from ANPEd meetings, and four works published in ENDIPE's book one[179], being not found any work from book four[180]. Added to these works, ten events in Languages. The total amount of works classified in this issue was 25.

The issue classification was an option for mapping, in a more objective way, the analyzed production. Therefore, this does not make the analyzed works less rich in scope or in the intersection of more than one aspect approached in the research. The subthematization was chosen in order to facilitate later research, being this one of the objectives of a State of the Art. Hence, when belonging to Didactics or Teacher Formation areas, the main point was the teacher formation in Higher Education of English Language teaching Degrees. The work has not been taken into account at any point when it does not deal with the specificity of this formation. It has been verified that there is a large number of research which deal with English Language teacher formation in basic education but not in higher education, therefore, lacking professors (*formador*).

It is evidenced that there is the need for an increase in research on teacher formation which circumscribe issues concerning teaching formation in Higher Education, especially in Post-Graduation Programs in Education, considering that the works found focus on Language events and in Post-Graduation Programs in

---

[5] ANPEd (National Association of Post-Graduation in Education) is a Brazilian non-profit association composed by researchers as institutional members, represented by the Post-Graduation Programs in Education – and individual members (researchers, teachers and post-graduation students) with the objective of developing and consolidating the post-graduation teaching and research in Education.

[6] ENDIPE (National Meeting of Didactics and Teaching Practice) is a scientific event in the Education area which assembles researchers and professionals (teachers and undergraduates) that work in Post-Graduation Programs in Education and deal with issues regarding the themes: teacher formation, teaching of the diverse disciplines and curriculum.

[7] Convergence and tensions in the field of teacher formation and work: Foreign Language teaching.

[8] Didactics, teacher formation and teaching work.

Applied Linguistics. It is expected that with a larger number of publications on this issue, there will be relevant contribution for significant changes to happen, improving the quality of Courses of English Language teaching formation, since there is investment in the continued formation of higher education teachers in this area.

2nd Research: Studies on teachers' professional formation and development: university professorality
Research of the type state of the art demands from the researcher a series of decisions related to the procedures to be undertaken. In this process, many challenges interpose the researcher, especially when related to the mapping of themes which encompass their object of investigation, definition of research sources, as well as ways of treating the *corpus* which constitute the state of the art. When describing the chosen directions, it is aimed at bringing to discussion not only the adopted strategies but also the difficulties and aspirations which have arisen along the way.

Sentiments of uneasiness and uncertainty were present along the development of the study. Questionings such as: *where to start*, *how to handle with the totality of knowledge produced*, *how to determine research sources and criteria of analysis* demanded not only the definition but especially the recalling of many of the procedures adopted.

The first challenge has been the **definition and delimitation of the object of investigation** to be presented on the thesis project. The explicitness regarding the central issue of the research to be undertaken, as well as the concepts which are tangent to the problematic of the study are essential for the starting point of the study state of the art. In this sense, the research – aiming at investigating the movements made by professors while in their professorality production – has raised the surrounding issues: their formation and professional development as teachers and University teaching. Consequently, these were the first descriptors defined in the study of state of the art.

The next step was the **definition of search sites.** It seemed as an important and valid strategy, recurrently used by renowned researchers in this type of study, the choice for scientific journals, important events in the area, theses and dissertations database. Therefore, the actions performed in these search sites were a constant challenge to confront the incompleteness of the collection. The number of scientific journals and works produced demanded an endless time for searching and reading. This way, it has been opted for directing the investigation to existing research groups in Brazil which are involved with studies regarding teacher formation, more specifically, the University teacher formation. This investigation was conducted in the research groups' directory available at CAPES[181] website (http://dgp.cnpq.br/diretorioc/).

In this process it has been reached the research groups which are part of South-Brazilian Network of Researchers in Higher Education (Rede Sulbrasileira de Investigadores da Educação Superior – RIES). This network has focused on configuring and promoting studies and research concerning Higher Education, more specifically University Pedagogy, congregating researchers and undergraduates, and also teachers who are interested in this issue, aggregating 54 research groups, thus being it opted for. This choice is reinforced by two aspects: firstly because of the importance of this network for the constitution of the field of University Pedagogy and secondly because of the way it has been divulgating its productions from summary works.

With the research site defined, a **first data mining** has been done with the objective of identifying the main themes of each research group. This research was favored by the existence of a work published by RIES, which has detailed information about the research groups linked to it, making viable the collection of the following data: fifteen (15) groups directed to university teaching and professionalization; seven (07) research groups directed to pedagogical practices and innovation; ten (10) research groups developing researches concerning subjectivities and subjects in the university; eight (08) groups focused on policies and practices in teacher formation; and six (06) research groups directed to national and institutional policies in higher education (Cunha & Broilo, 2008).

In this process were selected, for the **preliminary analysis**, groups focused on university teaching and professionalization (15), pedagogical practices and innovation (07), policies and practices in teacher formation (08). This analysis is supported by the identification of the leader researchers in each group and the reference to their curriculum *Lattes*, identifying the research projects developed and the theses advised in the last five years. In this step, it was necessary to make a subthematization, conventionalizing, in what refers to formation, the search in works which dealt with teacher formation in the context of professional performance, comprising concepts such as in-service formation and continued formation. The learning teaching and professional life cycles of teachers have also been considered guide concepts for the analysis. The selection of four (04) research groups with their respective investigations resulted from this process.

---

[181] Coordination for the Improvement of Higher Education Personnel

This stage demanded search in websites, theses databases, journals and contact with some of the leader researchers in order to request information about their research.

Once the *corpus* of state of the art was defined and collected, the **intensification on the process of analysis** has started since the reading of complete works, resulting in the elaboration of a **summary report of each work**. This record comprised different items: the author and the research group, the work title, the research problem, the goals, the procedures of investigation, the authors used, and the research results. This information has been recorded in spreadsheets, such as the following one:

Table 1: Individual Record Sheet

Author – research group	Title/ keywords	Research Problem	Goals	Main concepts used	Approach and investigation procedures	Authors used	Main findings

With the end of these procedures it was initiated the **mainstreaming research findings**, from the elaboration of new record spreadsheets, which gathered from three to four works. This record has ranked first the identification of approach points and agreement among works, concepts, and poorly approached works which suggested a need for development, weaknesses and strong points perceived.

Table 2: Collective Record Sheet

Author – research group	Title/ keywords	Research problem	Goals	Main concepts used	Approach and investigation procedures	Authors used	Main findings
Work A							
Work B							
Work C							
Approach points		Poorly explored concepts and development suggestion			Strong points		Weaknesses

This record model was very important for the **elaboration of the final report**, as it has made possible to find and remodel aspects of the developing thesis project – identifying aspects approached and consolidated in previous research – and to prospect study possibilities for the knowledge field presented. This process has also been essential for the argumentation and defense of the thesis project presented.

3rd Research: Extension Activities in Higher Education Institutions and Continued Formation of Teachers

The research which has inspired this study of state of the art aims at understanding how the dynamics of extension acts in teacher formation processes in basic education is established considering the network relation between university and school. During the elaborative process of the thesis project, the challenge of mapping the academic production relative to studies which involve the acts of university extension[182] in the field of continued formation of basic education teachers has presented as a need, especially when the Ph.D. process started, still in the period of project selection for the Ph.D. program.

Thus, from the study problem, a survey regarding the research approaching this issue has been developed. The purpose was to find and highlight the studies conducted in this area and also ascertain whether the intended research consisted of a theme demanding new research or was an exhausted theme.

In the course of this process, many questions have raised as for example: what strategies should be used in order to develop tracking of already produced research regarding this problem? Given the quantitative amount of academic production in post-graduation programs is it possible to delimit the main research involving the theme studied? Moved by such questions, the research mining referring to the investigated

---

[182] According to the National Policy on Extension, agreed by the Public Institutions of Higher Education in Brazil, based on the National Extension Plan originated in National Forum of Extension Pro-rectors (FORPROEX), document which defines the guidelines for university extension in the country, the **University Extension** involves one of the functions in the Brazilian university characterized as a scientific, cultural and educational process that articulates Teaching and Research in an inseparable way and makes viable a closer relation between the university and other social segments. The same document emphasizes that extension actions must be linked to the process of personnel formation and knowledge development.

theme has started. Initially, the work has directed to identifying institutions and organizations with national reputation in the field of Education responsible for the divulgation of researches in this area. This dynamics has been realized through the reading of theses and dissertations summaries and journals. And it was perceived that often the summaries could not manage to provide information referring to the whole research, in other words, the core theme of the study was made explicit but the idea of what the research really was approaching was not clarified. This fact has demanded the complete reading of theses and dissertations. However, this was a complex action because of the great amount of research in the area, and it has given rise to uneasiness due to the delimitation of time available to complete the research.

Given the circumstance, the first step was to restrain the reference sources for data collection. This way, it was opted for searching data in the virtual patrimony of National Association of Post-Graduation in Education – ANPEd, which corresponded to the period of the Annual Meetings (Reuniões Anuais – RA) from 2006 to 2010, respectively from 29th to 33rd RA. The adopted procedures were the following:

The 33rd meeting, in 2010, was chosen as a reference in the definition of Work Groups (Grupos de Trabalho – GT) which had proximity with the theme. In this meeting, the twenty-four work groups[183] were visualized so the theme could be approached by any of the groups, given the scope of the theme. The following procedure was adopted: when the keywords of the abstract indicated any possibility of emphasis on the issue, it was read, and if it also partly regarded the issue interests, then there was a complete reading of the work. The Work Groups which presented proximity with the theme were: State and National Politics (GT05), Teacher Formation (GT08), Higher Education Policy (GT11).

The following step was to map, through the spreadsheet records, all works of oral communications from these three research groups, from the annual meetings of the last five years, adopting the same procedure previously mentioned. This record included the identification of the following items: the Work Group to which the work was linked, the title, the keywords, and the problematization in the abstract. Thus, from the 370 works of oral communications presented in these three groups in the last five ANPEd's annual meetings, six works were related to the theme researched, being analyzed the conceptual elements articulated in the texts.

The exploratory study developed has made possible to outline a panorama of the research produced regarding the theme, a process which signaled the need for searching in other reference spaces which deal with University Extension. This is the challenge which has arisen from the strategies employed.

4th Research: Study of the Art concerning "Teacher Intellectual Autonomy"
This state of the art has aimed at surveying works and posters presented at ANPEd's annual meetings between 2006 and 2010, regarding the theme "teacher intellectual autonomy"[184]. ANPEd has been chosen because it is one of the most important and representative events in the research field of Education in Brazil, being a reference in monitoring scientific production in this area.

Regarding the adopted strategies, a research on ANPEd's website has been developed, in each link of the meetings in the last five years: 29th, 30th, 31st, 32nd and 33rd meetings, separately. The following step was to access GT08, make a record of all oral communications and posters presented each year in a digital document, concomitant with the summary accessed via the Internet. In the digital document, all works (oral communications and posters) were recorded. Subsequently, the works which dealt with the theme "teacher intellectual autonomy" were selected. Together with the abstracts, visualized on the website, the criteria of analysis was to verify whether there was the subject in question in the following parts: title, keywords, and text content; respectively. When the theme was not visible in the title, the keywords were immediately analyzed, where it was possible to identify the presence or absence of what was being searched for. The

---

[183] **GT02 – History of Education; GT03 – Social Movements and Education; GT04 – Didactics;** GT05 – State and Educational Politics**,** GT06 – Popular Education**,** GT07 – Children Education (0 to 6 years old)**,** GT08 – Teacher Formation**,** GT09 – Work and Education**,** GT10 - Literacy, reading and writing**,** GT11 – Higher Education Policy**,** GT12 - Curriculum**,** GT13 – Elementary Education**,** GT14 - Sociology of Education**,** GT15 – Special Education**,** GT16 – Education and Communication**,** GT17 - Phylosophy of Education**,** GT18 – Education of Young People and Adults**,** GT19 – Mathematics Education**,** GT20 - Psychology of Education**,** GT21 – Education and Ethnical-racial Relations**,** GT22 – Environmental **Education,** GT23 - Gender, Sexuality and Education**,** GT24 - Education e Art**.**

[184] We understand as **teacher intellectual autonomy** the constant *teacher's learning to learn*; it is the continuous search for knowledge and the (re)construction of knowledge, increasing its possibilities of practical and theoretical actions in a reasoned way, thus contributing to the teachers self-assurance in making decisions face to challenges of the teacher professional routine (GROLLI, 2000; CONTRERAS, 2000).

reading of the abstract content corroborated with the content of the keywords, signaling, though briefly, the conceptual perspective of the referentials selected or adopted by the authors of the analyzed work.

Sometimes, the selected theme was found only in the textual content of the abstract and not in the keywords or the title. It was understood that, when considering the keywords, it is possible to identify the main themes which are approached in the complete works, facilitating the search for issues of interest. However, many works have not presented keywords and, in others the keywords were not sufficiently clear in order to anticipate to the reader the theme of the research. The result of this research of 'state of the art', regarding the theme 'teacher intellectual autonomy", can be visualized in the following table:

Table 3: State of the Art of the Issue "Teacher Intellectual Autonomy"

WORKS OF ANPED NACIONAL - GT 08 "TEACHER FORMATION" ISSUE "TEACHER INTELLECTUAL AUTONOMY"							
ANNUAL MEETINGS		ORAL COMMUNICATION			POSTER		
	No. of works at the meeting	No. of works	No. of works regarding the issue	No. of works which approach the issue	No. of works	No. of works regarding the issue	No. of works which approach the issue
33ª	24	21	0	0	3	0	0
32ª	79	21	0	0	58	0	0
31ª	26	18	0	1	8	0	0
30ª	39	31	0	0	8	0	0
29ª	42	28	0	0	14	0	0
TOTAL	210	119	0	1	91	0	0

This table is presented as a suggestion to show the results of the search procedure and also obtain a broader view of the findings, allowing sketching a panorama, in an attempt to draw a possible representation and understand the present situation in the area concerning "teacher intellectual autonomy".

This way, it is possible to say that from the 210 works presented at GT08, in the last five ANPEd's annual meetings, 119 were oral communications and 91 were posters. From these 119 oral communications, no work approached the theme "teacher intellectual autonomy" and only one approximated with the theme when approaching "teacher autonomy". From the 91 posters analyzed, no work approached the theme and there also were not approximations. Considering these findings, it is possible to draw the conclusion that there still is a significant silence regarding the analyzed theme, which suggests the need for research in the area of teacher formation about the issue "teacher intellectual autonomy".

CONCLUSION

The purpose of this work was to discuss, from different perspectives, the adopted strategies, the possibilities and the challenges which circumscribe the production of state of the art. The research's individual trajectories, here presented, signal choices and systematizations representative of the time of elaboration of each author's thesis project. This search format allows us to point out that the more strategies are used, possibly the more they are going be recurrent. We emphasize that the elaboration process of state of the art remains under construction, considering its inherence to the theses' production.

The intention of sharing the paths followed in order to establish the state of the art has arisen, mostly, from the difficulties found in the process of search systematization, as well as the acknowledgment of the need for stimulation of discussions regarding possible ways for the development of works of this nature. Due to reflections generated during this process, it is possible to infer and to indicate some aspects considered important to be highlighted in state of the art:

- Delimitation of the object of investigation related to the intended research, in other words, the core theme of the thesis and concepts resulting from it.
- The need for the development of an exploratory study with the intention of acknowledging the scope of the territory to be investigated. It makes possible the identification of reference sources, patrimony and search sites.
- The challenge of considering the totality of works produced in the field of Education has become a complex action of search and analysis, given the relativity and incompleteness inherent to research of this type. This has demanded from the researchers the necessity of opting for deeper readings, in detriment of handling a great amount of publications.

- The demand of a more accurate delimitation is substantial for the development of state of the art. Therefore, it is pointed out the importance of the adoption of criteria which will delimit the boundaries of search sites. These criteria need to consider the reference and relevance for the investigated field.
- The selection of works of state of the art can be made through descriptors related to the themes which circumscribe it – the identification of the title, keywords and abstracts. Taking into consideration the fact that, many times, abstracts present weaknesses, leading to mistakes in understanding the issue investigated, it is essential to read the complete work.
- The *corpus* analysis demands a process of immersion in the works collected with the intention of subthematizing to deepen the studies and to draw conclusions.

In a conclusive dimension, the realization of state of the art consists of a fundamental process for the development of a thesis, giving support to the argumentation and the legitimacy of the research to be developed. We have emphasized its potentiality to increase the knowledge concerning the theme of a thesis, stimulating openings to new reflections concerning the object of research. Lastly, it is hoped that the theoretical and methodological questions approached in this text motivate discussions related to production of state of the art.

Abstract: This paper focuses on training experiences, in undergraduate and postgraduate degrees, aiming at highlighting the teaching and learning process in higher education (HE) as a privileged space for (re)affirmation of academic autonomy and construction of the professional autonomy. The object of research consists of formative experiences developed in University of Porto, University of Aveiro and Federal University of Pernambuco, and is three-fold: (1) factors affecting (un)success of university students through a reflection on the limits and possibilities of HE students, (2) teaching relationship within the scope of undergraduate students' supervision, covering issues related to possibilities of this training initiating dialogues with the autonomous know-how, (3) construction of the teacher professionalism in the initial teachers' training, placing the challenge of shared management of the organization of the teachers' pedagogical work. Thus, this work constitutes a dialogue between different interwoven experiences, aiming at understanding teachers' knowledges and practices, as well as students' experiences, reaffirming the privileged nature of HE.

Keywords: Academic success, autonomous educational relationship, higher education teaching.

INTRODUCTION

Over the past few years, an increasing complexity has taken place in the relationship between students and the Higher Education Institutions (HEIs) that they attend. On the one side of this relationship are the students who, as older and more mature students, in comparison to their peers in the formal educational system, have needs, requirements, expectations, that is, specific characteristics that distinguish them from the other students. On the side of the HEIs, there is an environment of increasing competition, resulting from massification and marketization of higher education (HE) and demographic stagnation, and consequent over-sizing of the educational offer. In this new competitive environment, HEIs are facing many challenges, and one of the most important is the need to know how to deal, keep satisfied and graduate students who now have a quite different socio-demographic profile from the one they had just a few years ago, and a much more diverse population with a high level of demand has emerged in recent years (Navarro, Iglesias & Torres, 2005). The average graduation rate, among the 24 OECD countries, was, in 2008, 38%, with the rate being 45% in Portugal (OECD, 2010). Thus, it is critical that HEIs develop and implement measures and strategies to increase retention rates of students, that is, they face the challenge not only of meeting the objective of recruiting the largest possible number of students, but also of being able to keep them in the institution and graduate them, and a knowledge and a clear understanding of the factors that influence student performance is crucial for defining the orientation of these strategies (Murtaugh, Burns & Schuster, 1999).

Within this theoretical framework, we present, in exploratory terms, the practice and knowledge of teachers and the relationship in the processes of supervision and mentoring of undergraduate and post graduate students in Portugal and Brazil. We, therefore, define an experience of autonomous and educational relationship in Portugal, and focus on the recognition of the importance of shared management of the organization of the teaching pedagogical work in HE, examined from an experience in Brazil. In an empirical illustration, the aim is to unveil factors that enable us reflecting on students' autonomy and success and, ultimately, to bring an understanding that is informed by the everyday and that may be extended to a greater understanding of the requirement of teachers' knowledge in HE.

STUDENT SUCCESS IN HE: DEFINING STUDENT SUCCESS

The literature on the topic of student success in HE reveals a considerable number of definitions of the concept. Kuh *et al.* (2006) state that the most commonly incorporated elements in the definition of this concept are quantifiable indicators, such as enrolment rates in HE, grades, persistence in the transition from first to sophomore year, number of years that students take to complete their degree, and finally obtaining the degree, the latter indicator being the "most definitive measure" to assess students' success of (*ibid.*: 5). Thus, students' success may be defined through the use of traditional measures of academic achievement, such as ratings in HE access exams and grades achieved throughout the academic path, which represent students' progress towards attaining the academic degree. However, measuring the degree of students' success only on the basis of quantifiable indicators can be reductionist and exclude important aspects of the student's life that are not subject to quantification, by failing to provide relevant information in terms of students' intellectual and personal development, seen as results of their academic experience (Cheng, 2001). In this line of thought, and still according to Kuh *et al.* (2006), there is an extensive array of other indicators, which have a qualitative and more subjective nature, that may prove that a student had, or had not, success in HE, which consist primarily on desired outcomes that have benefits to both the student and society. Academic success is, thus, a broad concept that, at first sight, involves the commitment of the student to obtain grades that enable him/her to carry on to the following academic year, but more than that, it implies a sense of fulfilment and achievement of important personal and/or collective goals, that is, it involves the student as a whole and goes beyond the cognitive or academic success *per se* (Hunter, 2006).

In short, if this polysemic concept is, for some, seen as the most important of all measures of institutional effectiveness, which reflects the quantity and quality of educational experiences attained by students during their pathway in HE, for others this concept, given its ambiguity, simply cannot be measured (Alfred *et al.*, 2007). Therefore, academic success can be defined as a composite and complex process that involves the interaction of a myriad factors related, on the one hand, to the institution and, secondly, to the student's personal features (Mills et al., 2009).

FACTORS AFFECTING PERFORMANCE AND SUCCESS OF HE STUDENTS

A wide range of theories and conceptual models attempting to explain HE students' behaviour of persistence or dropout may be found in literature. These theories consider HE students' success as the persistence and achievement in educational terms, that is, a student is successful when he/she attains the desired degree or diploma that proves that he/she successfully completed his/her studies (Kuh *et al.*, 2006). The conceptualizations that have been made about factors influencing students' performance and success may be grouped as follows:

Sociological perspectives

According to the theories framed by the sociological perspective, when the student joins the HEI, he/she brings along individual characteristics that will interact with the characteristics of the institution he/she joins, and this relationship will influence and determine both his/her performance and results in academic terms and his/her decision of either remaining in the institution or dropping out of it. When a student joins the HEI, he/she carries a set of individual characteristics, such as family background, individual attributes and previous educational experiences. This set of characteristics influences not only the student's academic performance, but also his/her commitment to his/her objectives and to the institution itself. These attributes, when interacting with the structural characteristics and standards of the institution, will lead to different levels of interaction and integration of individuals in the institutional environment (Tinto, 1975; Terenzini & Pascarella, 1980), and the low level or absence of this interaction will hinder the establishment of formal patterns of social interaction (Spady, 1971), increasing the likelihood of student's failure and subsequent dropout from the of the HEI.

Organizational or institutional perspectives

The organizational perspectives highlight institutional structures and processes of the HEI that may affect students' success. The theoretical models that are framed by these perspectives (Bean, 1980; Berger & Braxton, 1998; Terenzini & Reason, 2010; Swail, Redd & Perna, 2003, among others) argue that it is necessary to consider the background characteristics of the student and his/her interactions with the environment of the HEI. Once within the institution, the student interacts with it, perceiving the objective measures, such as ratings, and the subjective measures, such as the practical value of academic training and the quality of the institution. These variables will influence the degree of student's satisfaction with the institution. The higher the level of satisfaction, the higher the level of institutional commitment, this being a

key factor in the likelihood that the student will remain or leave the institution (Bean, 1980). Thus, the ways students perceive and experience the organizational attributes of HEIs they attend are a potential source of influence on their integration into the academic universe, and students' integration in the HEI is potentially influenced by how they experience the organizational attributes (Berger & Braxton, 1998).

Psychological perspectives

These perspectives advocate that the student's personality traits help or hinder his/her perseverance when facing HE challenges. Thus, students with a better developed self-concept are more self-confident about their chances of success, while students with low self-confidence have increased odds of giving up when faced with setbacks and difficulties in their academic career. Moreover, these perspectives also argue that students who have an internal locus of control believe they can successfully overcome the obstacles, while students with an external locus of control believe that their fate is sealed, and hence, they will not succeed regardless how hard they strive, and they ultimately, in most cases, give up. It is especially in their freshmen year that young people assess and compare their previous experiences and expectations regarding the HEI's academic and social community. If these expectations are not met, there is an "early disenchantment" (Braxton, Vesper & Hossler, 1995: 596) with these communities, which can lead to more limited interactions and a difficult integration into them. In addition to this lack or difficulty of the academic and social integration, it is unlikely that these students make commitments later on, both with the institution and with the goal of completing their studies. Thus, the more committed students are, either with the institution, or with the goal of completing their studies, the greater the degree of importance they attach to the pursuit of their expectations for HE. The involvement of students has also, according to Astin (1975; 1984; 1999), a leading role in their loyalty towards the institution attended. These types of involvement include academic involvement, involvement with teachers and involvement with peers, among others, fostering increased learning and decreasing the likelihood of dropping out. Additionally, the coping behaviours are used by Eaton and Bean (1995) to try to explain the factors influencing the student's decision to remain or to leave the institution. Coping behaviours are mechanisms, described as behavioural choices, that the individual uses to cope with stress and to adapt to a new environment. Concerning specifically HE students, the coping behaviour is the way the student adjusts to the difficulties, at the academic and social levels, that he/she faces when he/she joins HE. Adapting to this new environment, which results in the student's social and academic integration, will determine his/her intention to remain or leave the institution. In short, by seeking integration into the new institutional environment, students go through various psychological processes; successful students achieve a positive self-efficacy, have less stress, increase their effectiveness and have an internal locus of control. Each of these processes enhances the student's motivation, causes for his/her academic and social integration and increases the odds that he/she remains in the institution and attains success.

Cultural perspectives

From the cultural standpoint, the interactions between the various individuals composing a group influence the institutional environment in which this group is integrated. Particularly with regard to the HE arena, the interactions that occur between the various institutional actors change, on the one hand, students and, secondly, the institutional environment. According to this, the issue of dropout is, first of all, a socio-cultural phenomenon, that is, when individuals decide to leave the institution, that decision is also shaped by cultural forces. These perspectives are based on a set of propositions about the early school leavers, namely the fact that the student's culture of origin is a mediator of the importance attributed to the fact of having an academic degree, the importance of knowing the student's home culture in order to realize the student's ability to integrate the institution's culture and, finally, the fact that the probability of persistence is greater the shorter the distance between the student's home culture and the HEIs' culture (Kuh & Love, 2000).

Economic perspectives

According to these perspectives, students weight the benefits and costs of attending HE and of participating in numerous activities that it offers them. Thus, if the student calculates that the cost of an activity (e.g. studying abroad for a certain period of time) is greater than the return on the investment, there will be increased odds that he/she does not seize this opportunity. Ultimately, this balance in terms of the overall student experience in HE may lead, depending on the result, to the dropout from the system. Costs, within this context, stand for economic spending with fees and expenses with food and lodging, among others; benefits mean the representations that students have on future earnings and other non-tangible dividends, as the increase in intellectual capital and a higher quality of life. The financial support takes a leading role here; in fact, studies show (Cabrera, Nora & Castaneda, 1992) that students' satisfaction with financial support to

their academic path may reduce their concerns about the economic aspects, enabling them, thus, to spend more efforts and energy in their personal academic and intellectual tasks. Hence, financial support is important not only because it equalizes opportunities between students of high and low incomes, but also because it facilitates the integration of students in the academic and social spheres of the institution and their commitment to remain in the HEI.

AUTONOMOUS AND EDUCATIONAL RELATIONSHIP IN HE

This text intends to accomplish a sustained narrative about the teaching relationship in HE within the scope of the under-graduations and supervision of graduation students[185]. Our issue concerns the analysis of prospects related to the possibilities that this training triggers dialogues of autonomous know-how on students. It is about understanding the possibilities that arise in the face of a training that is focused on relational perspectives and of communication with students, in what ways may the teaching knowledges influence, or not, students' autonomy and decisions, both concerning other key relationships with knowledge, and as relationship to be established between teacher and student.

We believe in a supervision and in a principle of work with students based on autonomy and participative or collaborative leadership that puts the emphasis on the group, the team and its enthusiasm (each and all are and can be leaders), shaping, this way, a team of thought that allow us to be leaders of our pathways and their interaction. We commonly use an ethic of strong and emotional relational principle that results in an *Autonomous and Educational Relationship* which expressed and expresses at all levels of contents building, work and research. It is fulfilled in strengthening the autonomy needed by strong relations. It is these strong ties that bound us, which have established and are established, that link and intertwine into an ethical dynamic of knowledges and affections between teacher and students. In fact, we have emphasized this learning because today's orientation is indebted to the experience as a supervisor, where we could enjoy both scientific rigor and care that allowed following with confidence and in autonomy. There is a feeling of gratitude and courage in the testimony that surely reflects a communicative and relational involvement.

In the present paper, we will stress an orientation that sometimes accompanies and sometimes troubles students and to whom it permanently adds more doubts. This supervision and mentoring are based on the development of a relationship of mutual openness and trust, yet true to critical goals in an exercise of autonomy, analysis and clear curiosity. And in this sense, thus, we basically move towards this relationship supervisor/supervised, of a shared, debated and choicely vision on these issues, so we walk together in the spirit of "*at the meeting*, she distributed wisdom and guided anxieties, doubts and made me see light. She revealed, in her role, the true ability to be more teacher." (MLF6[186]).

The work of supervision and analysis becomes a labour of will, of want, and of reinforcement of (other) knowledges. From this point of view, it is a demanding task that calls for a new relationship with knowledge that presupposes desire of understanding knowledge, "This relationship of openness and enlargement fascinated me, because teaching and learning requires interaction, as one only learns and teaches if one enjoys interacting" (LC4).

An "Educational Relationship", as they say (GAI5), begins, a relationship that is defined as a magic and affectionate one, yet demanding in its form of relational co-accountability experienced (felt), in a communicative and emancipatory involvement.

---

[185] For this, we use the experience of 12 years teaching and working in a curricular unit entitled Human Communication and Relationship, where we were given the opportunity to work and develop the contents with approximately 300 undergraduate students in Educational Sciences and more recently with Master students – in Education, Health, Science, Astronomy, Nursing Service and Teachers Continuing Training – totaling approximately 400 students. In this universe, we also account for Master (14) and PhD (5) supervisions, as well as the completion of monitoring and training of seven Masters in Educational Sciences and the participation in more than 20 panels of Masters exams, both in the University of Porto and in the University of Minho. With this diversity of experiences of supervision and mentoring to groups of students, we wish to illustrate the teaching relationship and, more specifically, the specificity of the narrative and relational experience, considering also students' feedback and interaction.

[186] Use of some encoded excerpts and testimonies from graduate and undergraduate students, obtained through the evaluations of the courses, the presentation of exams and teachers' satisfaction and evaluation surveys. Note that they show satisfaction because that is the general reality; however, in this picture presented in the graduate courses, there were three supervision dropouts and one case of dissatisfaction with the supervision but that, nevertheless, attained the diploma within the deadline.

There is, hence, the assumption of certain urgency in the visibility of affection in a contemporary problematic and adverse social context, and in the organizational constraint of HE, bringing the relationship in an warm dimension, the place of achievements being the meeting of the student with him/herself, with others and with the world, and not the clash with the teacher. The success in HE also, as the place of the choicely relationship stated in: "I appreciate the affection. I thank all those who, in relationship, have been with me in this moment of graduation" (GAI5).

We admit, following Goffman (1993) and Kaufmann (2005), that this may be a "cotton-candy" look (*ibid*., 2005:10), perhaps a sweet utopia of human Relations (humanized) at the HEI.

But note that other authors have recognized the lack of alternatives to contemporary societies based on capitalist and bureaucratic models. For instance, Fromm (1999) suggests that new models of social reconstruction should be examined, in order for the imagination to visualize other alternatives. On the basis of this assumption, the author examines the "two basic modes of being in the world: the *mode to have* and the *mode to be*" (1999: 37-38). And through this perspective, the author revisits some "common places" and gives us an exciting new vision, showing us new ways for humanity. We highlight what he says on the sense of *learning* in each mode: "Students who are included in the existence mode *to have*, hear a lesson, listening to the words and understanding their logical structure and meaning, and, as best as they can, note down each sentence in the notebooks, to later be able to memorize the notes they took and succeed in the exam. But the content did not become part of their individual system of thought, enriching it and expanding it" (1999: 37). Conversely, there are those"[...] students that relate to the world through *being*. In the first place, they do not attend any classes, even the first class of the course, making *tabulae rasae* [...] they are concerned with the issue because it is something that interests them [...] they receive and respond in an active and creating mode. In their mind, new questions, new ideas, new perspectives arise. Their way of listening is a living process. [...] Each student was affected and was modified: each one becomes different after the lesson" (*ibid*.: 38).

The relationship in an affectionate dimension

This affective dimension in HE manifests itself in the proximity and involvement, attained in the tutorial works and as a structuring dimension of an educational relationship based on students' autonomy and fostering. This is referred in their words: "Because she dropped the anchor always on time, renewing confidence and boosting options' making. Above all, because she led me to autonomously make my way, although remaining there whenever needed [...]" (MAS7).

Regarding the *Learning* concept, we encourage students to experience active and creative processes, witnessing a non aseptic experience, but rather one shared pleasure. It is about the development of a living and creative process that does not surrender, as a graduate student says, "the challenges presented, the concern, the dedication and the defiance of the teacher" (MAS7).

The work of teaching, research and analysis thereby developed, and reinforcing the idea, consists in a difficult approach and, therefore, we would like to make some other considerations; on the one hand, the general issue of theses' supervision and, on the other hand, the training experiences in HE.

Freire tells us (1997: 207-209) that the incentive to supervised students is in *daring to think* independently, that is, with autonomy, being close to them in their choices, sometimes quieting them and sometimes disquieting them; stating that "a dissertation may be worth more by what it demonstrates of curiosity, risk, spirit adventure on the part of its author, than another 'well behaved' one that reveals fear of risk and daring", and experience has, indeed, shown us these aspects. The dissertations have been worth more for their audacity, for letting talk the feeling, the affection, the emotion which carries the passion that stimulates us to progress, even though sometimes it requires the unthinkable, the assumption of a courage which is disused in our times. But is it worth for the students' words and gestures that tell us about "the warm colours and the touch of the finger" (LC2), and they "Thank for the knowledges, the availability, the support and the encouragement" (MDO3).

We, therefore, work with and for students, in a supervision based on developing a relationship of autonomy experienced on the openness, mutual trust and affection, yet faithful to critical and thorough objectives, built on a constant exercise of knowledges that are required to be ethical and understanding.

AN EXPERIENCE OF SHARED MANAGEMENT IN THE ORGANIZATION OF THE TEACHING PEDAGOGICAL WORK IN HE

The recognition of the didactic mediation as a function that sets the tone for teachers' work has made it possible to understand teaching as a relationships profession, requiring, according to Pimenta (2005), a training that enables building teaching know-how from the needs and challenges that teaching as social practice places on the daily life.

Such understanding meets the concept of teacher advocated by Roldão (2005: 117), regarding the understanding of the teaching professional as the "responsible for the mediation between knowledge and the student, because he/she – not others – is supposed to know how to do it, through intentionalized and tutored supervision of teaching actions leading to the real possibility." That is, according to Tardif & Lessard (2005: 35), it is "a work which object is not composed of inert matter or symbols, but of human relationships with people capable of initiative and endowed with a certain capacity to resist or to participate in teachers' action".

That understanding, although endorsed as essential in the training process and in the effective teaching practice, through research, is still little recognized by students in training – especially by the departmental nature of the organization of Diverse Undergraduate Courses[187], namely the separation specific subjects / pedagogical-didactic subjects. Such situation has been observed over years of practice in teacher training courses, through statements and behaviour of students on the complexity of the teaching profession. This fact has also been observed in research studies carried out on HE teaching, according to Leite and Ramos (2010), regarding the recognition of the relevance and need for didactic-pedagogic training for teacher performance in HE.

In this context, teachers' initial training has been the object of attention with regard to a review of principles that demands a new curricular structure. And the Diverse Undergraduate Courses in Brazil are undergoing a restructuring process, according to guidelines from the National Council of Education explained in Resolution 12/2008 (CCEPE/UFPE, 2008), aiming at training a teaching professional who is identified with the teaching role, considering the principle of inseparability between theory and practice, of the training-professional field approach and of the questioning of the teaching knowledge, requiring a substantial change in the offer of the Curricular Components of General Pedagogical Training and of the Components of Pedagogical and Teaching Practices – placing the initial training as an integral part of the professional teaching development.

Considering that the subject of Didactics is a curricular component of the block of the Teaching and Pedagogical Practices, which mediating nature enables a dialogue between the specific contents and the General Pedagogical Training, the experience herewith socialized is a proposal implemented to help in the construction of professional teaching with students of the Diverse Undergraduate Courses in the process of initial training, in order to situate the challenge of shared management of the organization of the teachers' pedagogical work, especially when it comes to choosing the training of investigation and intervention, through taking responsibility and co-responsibility in the process of collective (re)construction in conducting the activities of a curricular component.

This proposal has been developed since the second semester of 2008 in the context of the subject of Didactics at the Federal University of Pernambuco (UFPE), and, regarding the experience under analysis, in classes that bring together undergraduate students of: Performing Arts, Visual Arts, Biology, Dance, Nursing, Graphic Expression, Philosophy, Geography, Physics, History, Literature, Mathematics, Music and Chemistry.

This subject is offered in a Teaching Unit which is distinct from the Course of origin, physically and administratively, which requires facing the challenge of overcoming the dichotomy of specific content subjects/didactic pedagogical subjects, in the context of overcoming the Comenius view of the *treaty of the universal art of teaching everything to everybody* and the effort to enable the development of the understanding of teacher education within the perspective of *Didactics as Construction*, particularly in the sense ascribed by Cunha (2006) of rejecting static defining landmarks of didactic doings but acknowledge epistemologically grounded referents.

This fact has required an investment in creating new learning, in order to create opportunities for an understanding of the complexity of the construction of the teaching identity/professionalism - among others, needing to overcome (pre)concepts related to the figure of the teaching professional, in order both to recognize the teacher as a person/professional and, according to Gauthier *et al.* (1998), to understand the teaching profession as a *craft made of knowledge*s.

In this perspective, considering the complexity of the construction of the teaching identity/professionalism (Ramos, 2010), actions have been undertaken that have enabled the student in training to overcome (pre)concepts related to the classical view of the teaching profession, in order to enable a more systematic reflection, through the creation of new learning, in the context of overcoming the classical view about the teaching profession.

---

[187] Diverse Undergraduate Courses refer to the teachers training courses in the diverse areas of knowledge.

For this, the methodological proposal of the subject of Didactics is directed towards the permanent dialogue with the subjects about their know-how, through systematic and interdisciplinary reflection between knowledges and the proposed literature, and contributions have been identified:

- in the process of construction of the teaching identity/professionalism of the students involved, in the overcoming of (pre)concepts of the classical view of the teaching profession;
- in the systematisation of alternative elements for creating new learning in the process of the construction of the teaching identity/professionalism in the Diverse Undergraduate Courses;
- in the identification of elements to support the evaluation processes of undergraduate courses under restructuring.

Particularly with regard to the developed work of the collective organization of the subject, taking as its starting point the design of the didactic contract through the presentation and submission to group assessment of a proposal to conduct the subject, having as a basic resource the continuous evaluation of the established contract.

This proposal takes into account the understanding of the teaching professionalism as a relational movement process-product (Ramalho, Nuñez & Gauthier, 2004) and the importance of experiential knowledge in teachers' training.

FINAL THOUGHTS

In this paper, we intended to demonstrate that none of the models and theoretical conceptualizations present in the literature is, in itself, capable of accounting for all factors affecting the performance of HE students. However, these perspectives, analyzed together, provide a holistic view of the myriad factors that contribute for the academic experience of HE students to result in success or failure of their path, and that HEIs, on the one hand, should consider them in preparing their strategic plans, and that faculty, on the other hand, should consider them in the teaching/learning relationship established with students.

In this sense, then, we basically move towards this educational relationship, teacher/student or supervisor/supervised, from a vision that is both formative and shared, demanding throughout the way but with a heuristic theoretical framework and imaginary foundations, yet with basic concepts in the educational, pedagogical relationship, as Freire puts it, of "teacher and learner" – "those who teach learn while teaching and those who learn teach while learning" (Freire, 1997: 25), since this has been the most significant dimension of our relationship, as we found a dialogical praxis that, hand in hand, builds our uniqueness and the bonds between students and teachers.

Yes, bonds are established when we live the daily practice of a participated experience in HE, with students from various courses, but essentially around issues of Educational Sciences, Communication, Psychology and Sociology. The urge to think and to reflect the authentic teacher, who is able to live in a policy of autonomous life, to love, to engage and to act with students, has become essential in any educational arena. The authenticity of the essential teacher is less mediatic, is less visible, is more intimate, is felt in a real educational relationship – it is the essentially relational teacher. The identity of this teacher is indispensable in that it binds us and it moves with us towards the understanding of knowledges. In the words of students: "These classes have made us reflect, look inside ourselves and ask if we go to fight; and if we can and will try to build something, what more can you ask from the personal point of view?" (LM1).

The Brazilian experiences presented also corroborate these views, clearly seeking to enable the student in training to bring to the classroom the experiential knowledge – both from the perspective of contributing to a knowledge-learning dialogue and of transforming the experience into a *knowledge of the pedagogical action* (Gauthier *et al.*, 1998).

Experience has proved to be an opportunity to accompany a training process, besides the students in the class, of four graduate students in Pedagogy[188], who act as monitors of the subject, and of two Masters students of the Graduate Program in Education of the UFPE[189], aiming at establishing a real-time dialogue between support to teaching, knowledge building and possibility of training intervention.

---

[188] The Undergraduate Course in Pedagogy, although having teaching on the basis of its training, is equated to the Course in Educational Sciences.

[189] The two Graduate students are Scholars in the Program *Reuni* of Teaching Assistance, included in the Project for Restructuring and Expansion of the Federal Universities (REUNI), from the Edictal Reuni-UFPE No. 03/2010.

217 - Effectiveness of Cognitive Conflict Strategy In A Humanity Class

Yang Xiaohong[1] and Tang Qiuyuan[2]

Hangzhou Normal University, China
[1]54yxh2005@163.com , [2] forever110710@163.com

Cognitive conflict is central in cognitive development (Piaget, 1952). It is often induced by discrepant events—presenting information and/or experiences that clearly contradict students' existing conceptions and arouses in them an awareness of a momentary disequilibrium in the system of schemas (Limón, 2001).

According to Kwon(1989),cognitive conflicts arise from three types of disequilibrium : a) cognitive disequilibrium between one's cognitive structure and environment, such as discrepancy between a child's expectations and an empirical outcome that contradicts those expectations; b) metacognitive disequilibrium between cognitive schemata, as when two or more incompatible responses are aroused simultaneously; c) social-cognitive disequilibrium between a scientific conception recently learned or the conceptions of others and individual's past experience and /or the old conceptions, as encountered in group or class discussions.

Cognitive conflicts encountered in social interaction are called socio-cognitive conflicts. Though socio-cognitive conflict does not lead to greater advancement than cognitive conflict, social interactions would trigger cognitive progress by providing an obvious forum for the possibility of exchange of perspectives and helping to introduce anomalous data and create a demand to re-examine one existing beliefs in the light of incompatible ideas of other individuals. The socio-cognitive conflict encountered in the stage of social interaction motivates a cognitive restructuring that results in an increased ability to construct alternative models in the second, cognitive conflict stage (Monica Bucciarelli, 2004, 2007).

The first stages of thinking development are deeply social. Learners working alone are often unable to perform certain tasks because they cannot decenter, i.e., they focus on certain aspects of problems excluding others, more important aspects. However, learners in the interactions with participants at the same cognitive level as well as with participants at different cognitive levels, would find it easier to decenter as they compare their own point of view with another one which is different (more or less correct) . Each has to restructure his or her cognitive performance to coordinate it with the performance of others. This restructuring event in turn allows each participant to adopt a more advanced and consistent approach (Doise & Mugny, 1984; Siegler,1995).

The cognitive conflict process model developed by Lee et al. (2001) asserted that cognitive conflict consists of three stages: the preliminary stage, the cognitive conflicts stage and the stage of resolution . And in the second stage of the cognitive conflict process, four sub-stages are identified: a). recognition of an anomalous situation, b).interest, c).anxiety, and d). cognitive reappraisal of the conflict situation.

Responses to a discrepant event were classified into seven types: rejection, reinterpretation, exclusion, uncertainty, peripheral belief change, belief decrease, and belief change (Kang et al., 2004). Three specific criteria—believability of a discrepant event, inconsistency between a discrepant event and students' existing conceptions, and belief change after experiencing a discrepant event---- were used in classifying students' responses to the discrepant event(Chinn and Brewer,1998). According to Posner et al. (1982), cognitive conflict is generated when students feel dissatisfaction with their existing conceptions. Learners in a state of cognitive conflict are known to express signs of curiosity, arousal and inner drive to solve the conflict, as well as expressions of frustration, satisfaction and ultimately contentment as they arrive at a meaningful resolution (Zimmerman & Blom, 1983; Movshovitz-Hadar & Hadass 1990).

According to Limón and Carretero (1997), the seven response types to a discrepant event could be ordered into four levels in a continuum from the least acceptance of the discrepant event to the most acceptance of it. Rejection, reinterpretation, and exclusion were rated as a '0' because these responses produce no change in students' beliefs in their existing conceptions. Responses classified into uncertainty, which indicates no confidence in the validity of a discrepant event as well as an existing conception, were rated as a '1'. Belief change and belief decrease, the response types that indicate dissatisfaction with an existing conception at least to some extent, were rated as a '2'. Belief change, a function of entire dissatisfaction with an existing conception, was rated as a '3'. Rating '2' and '3' can be classified as the effective cognitive conflict.

According to Demetriou's model (1998), after the resolution of cognitive conflicts, cognitive development follows naturally at three levels of cognitive processing: 1) development in representation of information in the mind; 2) development of domain's operations, skills, and concepts; and 3) development in self-

monitoring, self-awareness, and self-regulation. At the first level,students generally place emphasis on the surface of the definition, and their understanding of the term at hand does not have any influence on their other fields. At the second level, learners have found some further information relative to the topic and can associate key aspects of the term, in an attempt to develop an explanatory mechanism to make sense of reality by establishing the logic relationship between the subject and practical learning. Learners 'concepts has changed partly at this level,. At the third level, learners have already create totally new schema to guide and control other parts of life. Maybe some superficial representation is similar, the core is quite distinct.

Cognitive conflict as a teaching strategy has been popular in science education research since 1980 (Stavy & Berkovitz,1980, Lee,1998). It focuses on destabilizing students' confidence in their existing conceptions through the presentation of contradictory experiences and then substituting their alternative conceptions with scientifically accepted ones, a common strategy incorporated in most conceptual change models (Chan et al.). It is found that an experimentally based contradiction played an important role in conceptual change (Levin et al, 1990; Kang et al., 2004). That is, students' belief changes were strongly mediated by their responses to anomalous data; the more that anomalous data were considered as valid and inconsistent with their existing beliefs, the more new theories were accepted.

According to Limón (2001), clearly highlighting the differences between students' existing conceptions and given contradictory data could help them to be aware of the differences between their own conceptions and the one introduced later by the teacher, and presenting conflicting experiences could help students to better reflect upon their existing conceptions as they attempt to give an explanation of the information studied

Present Study

Given the central role of cognitive conflicts in cognitive development and the effectiveness of cognitive conflict strategy in science education research, it is interesting to note that few research to date has been conducted to test feasibility and effectiveness of cognitive conflict strategy in humanities education, in which the introduction of a discrepant event through scientific experiment is impossible. Thus, the purpose of the present research was to find ways to bring cognitive conflict strategy to humanities education and to show its feasibility and effectiveness in a humanity class.

The most central concern of the present research is to build social interactions into the procedure of classroom performance that will provide a forum for the possibility of exchange of perspectives and help to introduce anomalous data and create a demand to re-examine one existing beliefs in the light of incompatible ideas of other individuals. For that purpose we have adopted an ACIR teaching procedure consisting of four stages: autonomous learning, cooperative learning, interactive learning and reflective learning.

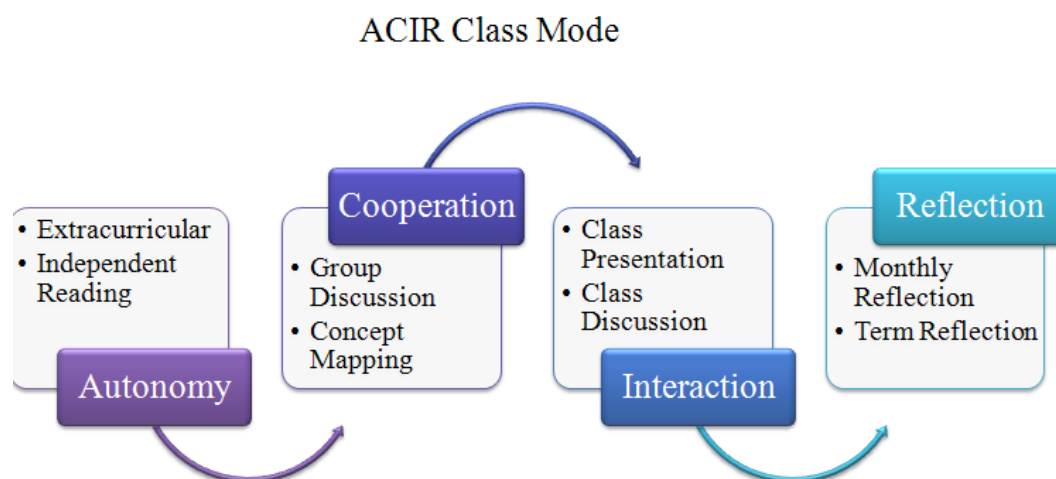

Figure 1: ACIR Class Procedure

Autonomous learning in Figure 1 serves to bring students into the preliminary stage of cognitive conflicts, during which student have to accepts responsibility for his/her own learning, determine objectives, select methods and techniques and evaluate what has been acquired (Van Lier,1996). Cooperative learning and interactive learning are two stages of cognitive conflicts and their resolution, where the thinking and interaction within the group or the class is characterized by the exchange of ideas, information, perspectives, attitudes, and opinions (Cohen, 1994). This kind of discussion generates thought-provoking questions,

explanations, speculations, justifications, inferences, hypotheses, and conclusions and such cognitive activities force students to clarify concepts, elaborate on them, reorganize thinking, or re-conceptualize the material in some manner. Interactive learning is to promote not only multiple connections between new ideas and prior knowledge but also to stimulate the construction of many different kinds of high-level connections (Bearison, 1982). Reflective learning is the last stage of the ACIR class procedure, the purpose of which is ''that reconstruction or reorganization of experience which adds to the meaning of experience'' Dewey's (1933). The reflective process, as embedded in Kolb's (1984) model of the experiential learning cycle, leads to recognizing values and beliefs underlying actions and decisions, considering consequences and implications, exploring alternatives and reconsidering former views (Boud et al., 1985).

One of the prominent factors in ACIR class that enable the class move continuously and smoothly from the stage of autonomy to the stage of reflection is an effective tool—concept mapping, which students are required to prepare before class and present in class by working cooperatively in their groups. With the help of this tool, students are exposed to the dynamic interaction with group members, classmates and the teacher, where their concepts are challenged, destructed and restructured. In this process of learning, critical thinking and creativity are encouraged, and students experience suffering, struggling, trying, finally reaching conceptual change and self-growth. Therefore, in this learning environment, conceptual change is not a mechanic and cold cognitive change, but a process which involves a strong awareness of resources. The class is computer-based and students can access online through a public email box concept mappings constructed by other groups as resources to stimulate their individual thinking in their preparation for class and meditate over mappings reconstructed in classroom interactions in their after-class reflections

Concept maps are diagrams indicating interrelationships among concepts and representing conceptual frameworks within a specific domain of knowledge (Novak, 1990). Concept mappings may be useful in revealing thought processes that generally remain private to the learner (Cohen, 1987). Cognitive theories, focusing on the structure of knowledge, underlie instructional approaches and assessments that involve concept mapping. According to Anderson (1984), structure is the essence of knowledge, and the process of constructing a concept map focuses the learner's attention on the structure of knowledge and the importance of knowledge integration. Through concept mappings, we can trail the learner's cognitive structure clearly

Concept mappings can provide a workable and effective expressed model for students to present their mental models concerning complex and abstract concepts (Johnson-Laird, 1983).The concept-mapping task also provoked conflicts, because in talking about relationships between concepts, students often had to choose between two opposite alternatives (Carla van Boxtel, 2002). Concept mappings are helpful for identifying the learners' prior knowledge before instruction. A concept map requires an explicit answer which leads to students' elaboration on almost all conflicts that arise. Becoming aware of one's own conceptions, knowledge gaps, and inconsistent reasoning can be considered very important conditions for conceptual change (Pintrich, Marx, & Boyle, 1993). Collaborative construction of concept mappings contributes to the learning of concepts, because both students are actively engaged in elaborative activities at the same time They are not only reflecting on and elaborating their own understanding but are also integrating and elaborating the input of their partners. (Carla van Boxtel 2002).

By integrating concept mapping into the procedure of ACIR class, the present research aims to investigate the following question:

> iii. How are cognitive conflicts generated and solved in the process of construction and deconstruction of concept maps ?
> iv. What is the distribution of cognitive conflicts over the four stages of ACIR class procedure?
> v. What is the long-term effect of the cognitive conflicts generated and solved in ACIR class culture?

METHOD

Participants

The participants in this study were 35 first year graduate students (4 male and 31 female) ranging in age from 22–38 years old who attended the correspondence author's course of Philosophy of Education in 2010, organized into 12 groups, each required to present their concept mapping to the whole class at their designated time.

Instruments

In order to find answers to the above-mentioned research questions, three instruments are adopted: 1) concept maps to track the online development of cognitive conflicts, 2) reflections to investigate the

distribution of cognitive conflicts over the four stages of ACIR class procedure and 3) word association tests to examine the long-term effect of cognitive conflicts generated and solved in ACIR class culture.

Concept mapping

Concept mapping, apart from its role to make the class move continuously and smoothly from the stage of autonomy to the stage of reflection, is used to keep the teacher focused on the process of meaning-making. And it is available for the teacher to track a students' conceptual development in relation to the curriculum.

Reflection

Two types of reflections are required from the students in order to keep track of the process of their learning and self-growth: 1) monthly personal reflection; 2) term reflection on personal growth and on group activities. There is no fixed standards concerning the form and content, and the only requirement is to write authentically.

Word Association Test

Word association test is a tool we use to measure the long-term effect of cognitive conflict on mental model. In the test, the respondent is given a stimulus word and required to freely write down 10 or 20 associated ideas that come to his or her mind, which are assumed to give relatively unrestricted access to mental representations of the stimulus term. Researchers have declared that ideas expressed within a word association procedure are spontaneous with fewer constraints than typically imposed in interviews or closed questionnaires, allowing thus the extraction of less biased results (Wagner et al., 1996).Word associations is one of the methods used for the evaluation of conceptual structures, as well as for ascertaining belief or attitude changes in psychology and sociology (Doise, et al., 1993; Ross, 2003).An analysis of these responses to a prompt word may give useful information about how words might be linked together in a person's mind" (Aitchison 2003:24).

Experiments with one word response association(one associate word to one stimulus word) with children and adults reveal predictable patterns of responses, with certain associates recurring at high frequencies, and the greatest majority appearing only once as idiosyncratic responses(Jay,2003:105). Such patterns are a social representation of the stimulus word, which is a form of social knowledge held by social actors elaborating and communicating their lifeworld in a symbolic way (Li, 2004:252) . As a particular type of social cognitive system, the social representation comprises of central as well as peripheral elements (Carey, 2000). The core is considered the conservative component that determines the organizational principle of the whole structure, and the periphery is the flexible component that helps the structure adapt to different frames of reference (Guimelli, 1998; Liu, 2004)

DATA COLLECTION

Word association pretest was administered during the first week of each semester and post-test during the last week. In the tests, participants were asked to write down 10 associates on the stimulus word "思考"(thinking or reasoning) to get the subjects' semantic representations of the stimulus word at the time of the tests. The associates were written on a hand-out form with ranked slots and a request to note down the time it takes the participant to finish the test. On average, participants needed approximately 3 minutes to complete the task. Participation in this study was voluntary and with no mark bonus given.

Concept mapping was done by using Inspiration, a visual thinking and learning software, developed by Inspiration® Software, Inc, in an online computer laboratory and students had the choice to join the collaborative reshaping or do it independently in their own way on their own computers. Concept maps were collected weekly as the course unfolded. The presenters of the task group each week were required to construct their mapping collaboratively and send their product to the class email box as resources available to other attendants to the class. During the process of mapping reconstruction in class interaction, the final outcome was put into file for later processing, together with the results of intermediate stages done either jointly or individually.

The assessment of students' performance in each semester were based on a final paper plus a term reflection and a reflection self-chosen from their monthly personal reflections. Term reflection is a time-tested tool in our ten-year-long research tradition with its emphasis on authenticity and students get much encouragement to describe their emotional experience in them. Reflections on monthly learning experience were collected on designated dates, commented, edited and fed back to students as shared resources .

DATA ANALYSIS

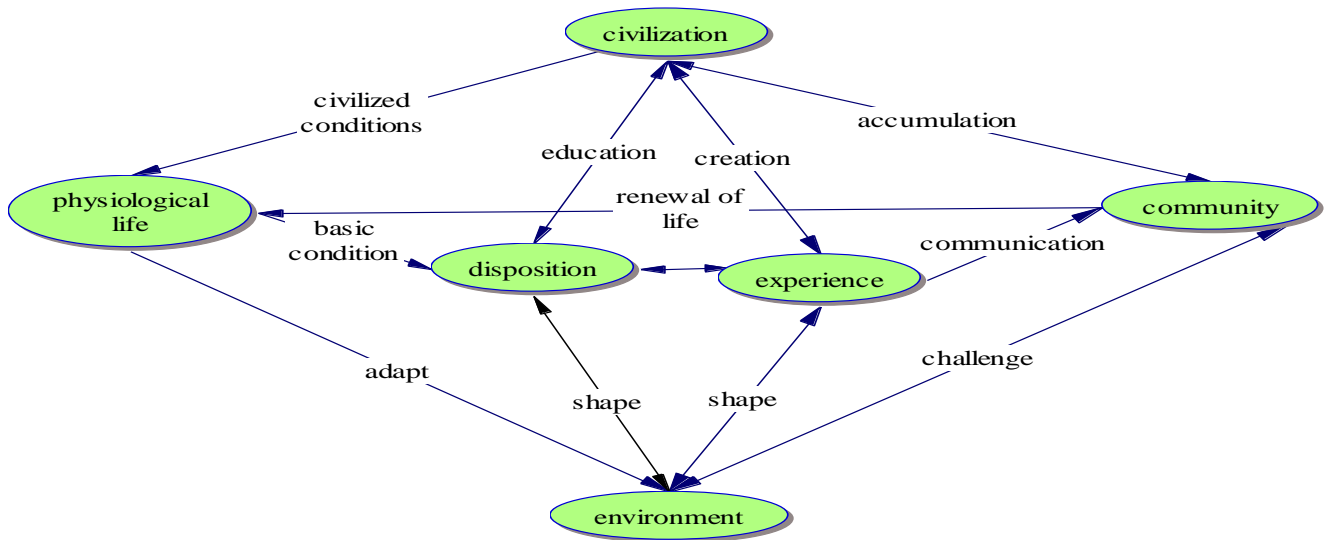
Data analysis was executed in three stages: a) analysis of concept mapping based on statistics of concepts and the links among them with its focuses on the structural change in the process of reconstruction and its aim to probe into mechanisms of conceptual change; b) analysis of reflections with its focuses on the generation and resolution of cognitive conflicts with a coding system based on Lee's cognitive conflict process model, Limón & Carretero's model of response types and Demetriou's model of cognitive development; c) analysis of word association test data involving structural reconstruction by hierarchical clustering based on the calculation of the frequency and the mean rank of each association and content analysis of the results of the structural reconstruction（Koskinas et al., 2000）


Figure 2: Concept Mapping Based on Dewey's Idea of Education as a Necessity of Life

RESULTS

Concept Mapping Analysis

The structure of a concept map can be assessed by examining： a) the number of the concepts in the concept mapping for the depth of understanding; b) the links(line, single headed arrow and double-headed arrow) between concepts showing students' understanding of the logic relationship among concepts; c) link words which are indicators of the clarity of their understanding.

Figure 2: Concept Mapping Based on Dewey's Idea of Education as a Necessity of Life

Figure 2 is a concept mapping reconstructed in the first session of the 2009 semester, with 6 concepts, 12 links and 11 link words. It was used as the starting position during a later session whose task was to integrate relevant ideas of Piaget, Vygotsky and Erikson into the mapping. Key concepts from these psychologists had been discussed and mapped in previous sessions, and ideas picked out for the integration included concepts like accommodation, assimilation, cultural mediation, social interaction, scaffolding,helper's schema, child's schema, internalization, life-stage challenge, successful resolution, favorable virtue(11 items).

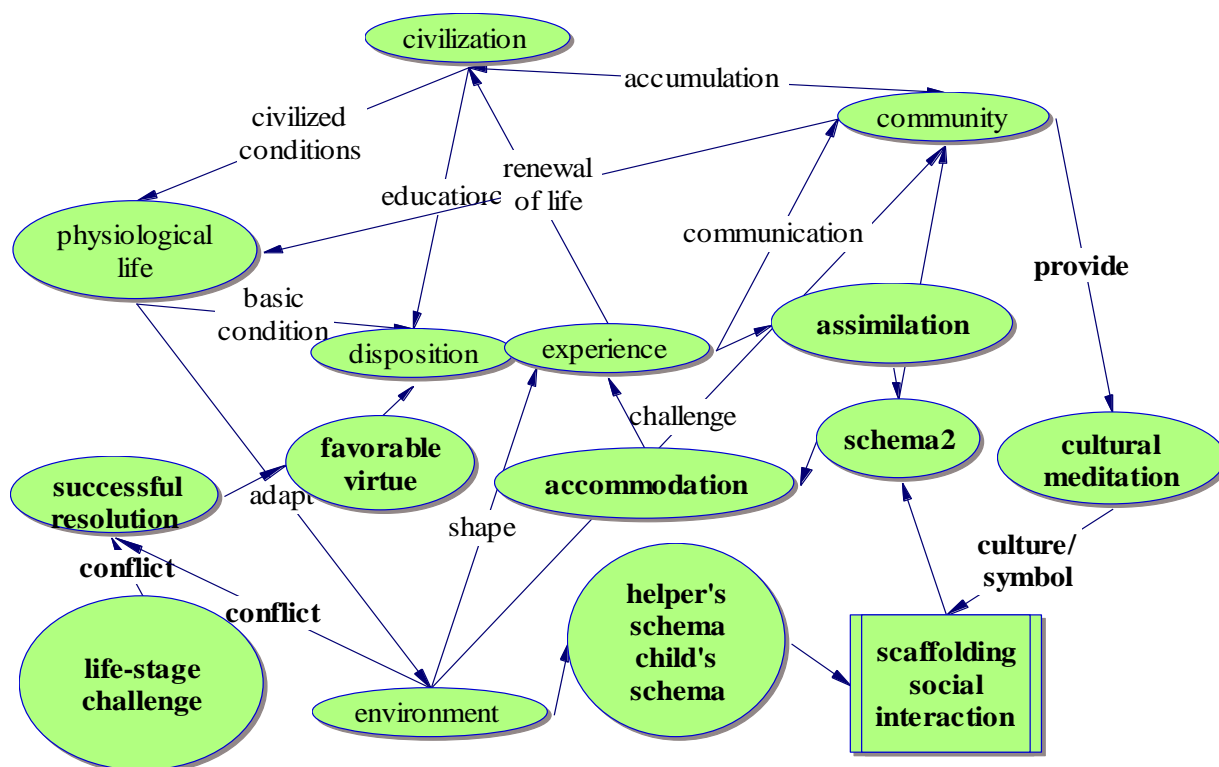
Stimulated by the interactive classroom efforts at an integration, one of the students drew four mappings independently and consecutively in the class, the first of which is shown in Figure 3 below:


Figure 3: A Concept Mapping to Integrate Dewey, Piaget, Vygotsky and Erikson

In Figure 3, concepts in slender letters are those in the original map as shown in Figure 2, those in bold letters are concepts that are to be integrated. Facing with the integrative task, the student took for granted the original map and simply added new ideas to wherever he thought they belong. The ideas from Piaget and Vygotsky were added to a space between the concepts "experience" and "community" and the ideas from Erikson were added to a space between the concepts "disposition" and "environment". It shows that he had already a good mastery of the definitions of the major concepts involved and understood the logical relationship among these discrete concepts.

However, an integrative task like this requires much more than that: concepts arising from different theoretical perspectives are to be revalued against each other, re-conceptualized and re-categorized before a new framework might emerge through the process. Traces of such an awareness in Figure 3 can be detected in the merge of "social interaction" and "scaffolding" into one node and that of "helper's schema" and "child's schema" into another, but they are far from enough. The student knew it himself, and his consecutive re-mappings show his persistent effort to address this inadequacy. The statistical features of his mappings are summed up in Table 1 against the features of the final collaborative mapping reconstructed in class.

Table 1: Statistical Features of Consecutive Mappings

Count	Mapping 1	Mapping 2	Mapping 3	Mapping 4	shared	Collaborative Mapping
concepts	15	16	13	11	7	6
links	23	24	21	15	4	9
link appellations	14	15	8	6	4	9

Table 1 shows a steady reducing of the numbers of concepts, links and link appellations through the four consecutive mappings, which is an indicator of the learner's awareness of and persistent effort at re-conceptualization: he refused to take for granted the given concepts and tried his best to penetrate into the depth of the meaning of them. In his second mapping, "social interaction" was changed from a discrete node into an appellation for the link between "helper's schema" and "assimilation" and "scaffolding" for the link between " child's schema" and " accommodation" . In his third mapping, "assimilation", "accommodation" and " cultural mediation" were merged into one node, indicating his effort to integrate Piaget's ideas with that of Vygotsky. The focus of his effort in the fourth mapping is directed toward a re-conceptualization of

1135

the three concepts of "physiological life", "disposition" and "experience" in the original mapping about Dewey and the merge of the three into one node shows his understanding of the overall structure of all the concepts involved, as shown in Figure 4.

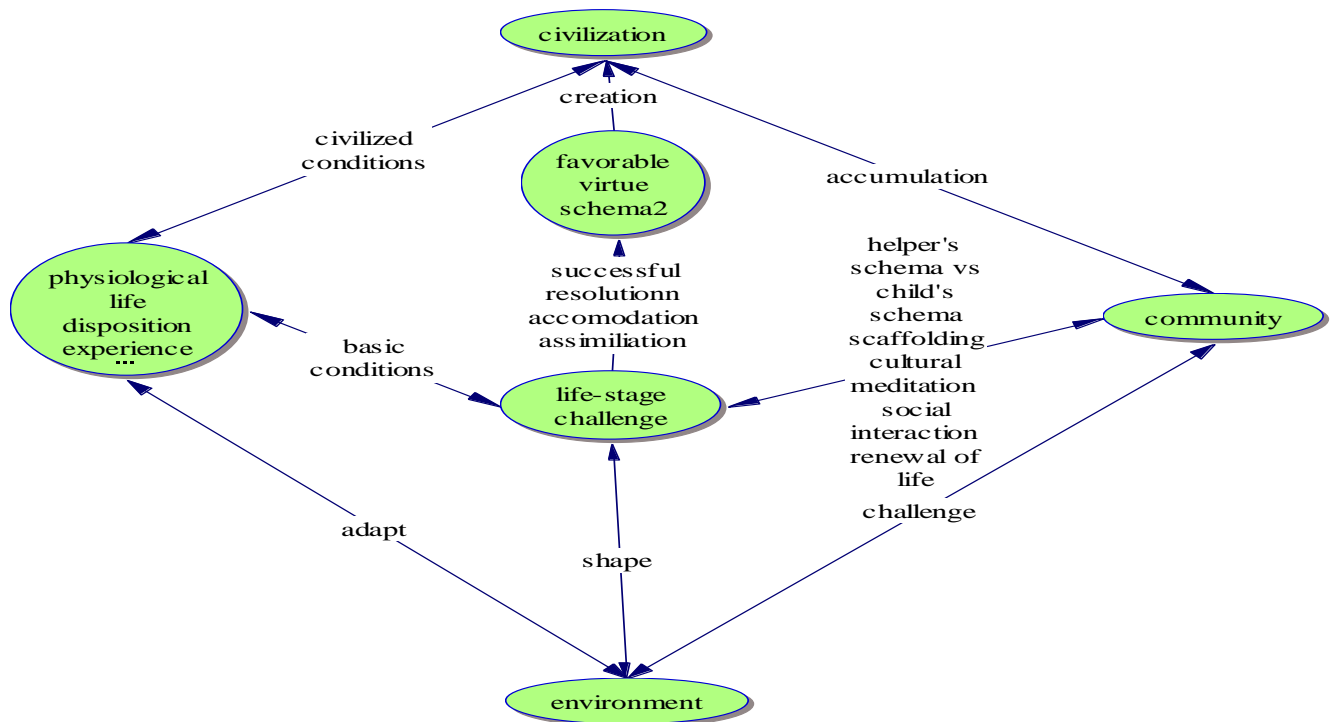
As shown in Figure 4, by merging the three concepts of "physiological life", "disposition" and "experience" into one node, the student demonstrated his understanding of the fundamental message conveyed by these authors: the dynamics of anthropological system composed of two dimensions: 1). civilization vs natural environment; 2). individual vs community. The collaborative mapping in Figure 4 moves further in this line of his thinking by two new reconstructions: a). merging Dewey's "renewal of life" and Vygotsky's" social interaction","cultural mediation","scaffolding" and "helper's schema vs child's schema" into an appellation to describe the multi-level dynamical interaction between the individual and community ; b). merging Piaget's "assimilation" and "accommodation" and Erikson's "successful resolution" into an appellation describing the growth process from life stage challenge to favorable virtue or schema 2.


Figure 4: A Collaborative Mapping on Dewey, Piaget, Vygotsky and Erikson

Table 1 shows that there are 7 concepts, 4 links and 4 appellations that remained unchanged throughout the reconstructive process. The concepts are "civilization", "community", " environment", "life-stage challenge", "successful resolution", "favorable virtue" and "schema2"; and the links and link appellations are those concerning the relations among "civilization", "community", " environment", and "physiological life, disposition and experience" as shown in Figure 4. These unchanged items are indicators of his overall understanding of the domain knowledge involved and serve as anchors in his reconstructive effort. Starting from these anchors and stimulated by the online classroom interactive process, he moved forward from one problem area to another, examined concepts drawn together from various theoretical perspectives, and successfully resolved the emergent cognitive conflicts by re-conceptualizing them.

Reflection Analysis
The coding system for the analysis of reflection consists of two dimensions: a) stages of cognitive conflicts and types of conflict resolution; b) source of cognitive conflicts arising in the ACIR class.

Table 2: Coding of Cognitive Conflicts

Stages	types of resolution	Abbreviation
the preliminary stage	x	C1
the cognitive conflicts stage	x	C2
the stage of resolution	rejection, reinterpretation, exclusion, uncertainty	$C3_0$
	New knowledge	$C3_1$
	New skills	$C3_2$
	New conceptualization	$C3_3$

The coding in Table 2 is an integration of Lee's cognitive conflict process model, Limón & Carretero's model of response types and Demetriou's model of cognitive development. Table 3 is statistics of reflection analysis of the data from the 2010 cohort using this coding system.

Table 3: Distribution of Cognitive Conflicts over the Rounds of Reflection

count	n^{th} Reflection				
Stages and resolutions	1	2	3	4	5
C1	20	11	7	8	3
C2	17	6	14	3	12
C3	25	48	35	27	43
$C3_1$	11	25	15	7	11
$C3_2$	8	17	6	10	17
$C3_3$	12	6	14	10	15

Figures in Table 3 shows three statistical trends: 1）the number of reflected preliminary stage experiences dwindles steadily and sharply from 20 in the first round of reflection through 11, 7, and 8 to 3 in the last round；2）the number of conflict resolution experiences rises up from 25 in the first round to 43 in the last round,3) of the conflict resolution experiences, the number of resolutions resulting in new knowledge fluctuates around a steady base-line figure 11, and the numbers of resolutions resulting in new skills and new conceptualization rise in ratio against those resulting in new knowledge.

The other dimension of reflection analysis is concerned with the distribution of cognitive conflicts over the types of sources of cognitive conflicts arising in the ACIR class, the coding system of which is shown in Table 4.

Table 4 : Coding of Cognitive Conflict Sources

Types of cognitive conflicts	Sources	Abbreviation
Intrapersonal	Reading material	R
Social	Class mode	CM
	Teacher	T
	Collaborative construction	C
	Events in class	Ein
	Events out of class	Eout

Table 4 shows the coding system of cognitive conflict sources: intrapersonal cognitive conflicts arising from reading, social cognitive conflicts arising from students encountering the ACIR class mode, their interaction with the teacher, their participation in collaborative construction and their engagement in events in and out of class.

Figures in Table 5 are blends of C1, C2 and C3s and the figures in the bracket indicate types of cognitive conflicts occurring in the designated stage of class procedure, the first position being for C1, the second for C2, the third for $C3_0$, the fourth for $C3_1$, the fifth for $C3_2$ and the sixth for $C3_3$. Take the first box for example, 13 indicates the total number of cognitive conflicts occurring in reading, of which there are 4 C1s, 2 C2s, 0 $C3_0$, 6 $C3_1$s, 1$C3_2$ s and 0 $C3_3$.

The 5th reflection is the term reflection, and students tend to write about their general impression and emotional attitude instead of going into the details of specific events which were fading away, which might be an explanation for the absence of any mentioning of specific events in and out of class in the 5th round of reflection.

Table 5: Distribution of Cognitive Conflicts over Cognitive Conflict Sources

Nth Reflection	R	CM	T	C	Ein	Eout	Total
1	13 (4,2,0,6,1,0,)	16 (3,3,1,2,5,2)	15 (5,4,0,3,1,2)	2 (1,0,0,0,1,0)	7 (1,3,0,0,0,3,)	8 (4,2,0,0,0,2)	61 (18,14,1,11,8,9)
2	22 (5,0,0,13,2,2)	9 (1,1,1,1,5,0)	8 (1,0,0,2,4,1)	1 (0,1,0,0,0,0)	6 (1,1,0,3,0,1,)	14 (2,2,0,3,6,1)	60 (10,5,1,22,17,5)
3	13 (3,1,0,7,0,2)	15 (1,3,1,4,4,2)	8 (0,3,0,2,2,1)	2 (0,0,1,0,0,1)	8 (1,3,1,0,0,4,)	5 (1,1,1,2,0,0)	52 (6,11,4,15,6,10)
4	10 (3,0,0,3,2,2,)	10 (2,1,2,1,4,0)	5 (1,0,1,0,2,1)	1 (0,0,0,0,0,1)	3 (0,1,1,0,1,0.)	11 (2,0,0,3,0,6)	40 (8,2,4,7,9,10)
5	14 (3,3,0,6,0,2)	24 (0,4,6,1,5,8)	21 (0,4,0,3,11,3)	5 (0,1,0,1,1,2,)	0 (0,0,0,0,0,0,)	0 (0,0,0,0,0,)	64 (3,12,6,11,17,15)
total	72 (18,6,0,35,5,8)	74 (7,12,11,9,23,12)	57 (7,11,1,10,20,8)	11 (1,2,1,1,2,4,)	25 (3,8,2,3,1,8)	38 (9,5,1,8,6,9)	277 (45,44,16,66,57,49,)
percentage	25.99%	26.71%	20.58%	3.97%	9.03%	13.72%	100%

Table 5 shows that the total number of cognitive conflicts is 277, with 45 C1s, 44 C2s, 16 $C3_0$s, 66 $C3_1$s, 57 $C3_2$ s and 49 $C3_3$, which indicates a very balanced cognitive development going from the preliminary stage through the conflict stage to the resolution stage. Of the 277 in Table 5, 72 belong to the category of intrapersonal cognitive conflict, occurring in the reading period, taking 25.99% of the total, the second largest share among the six sources listed in the table. 205 of them belong to the social cognitive conflicts, with those connected with the class mode standing at 63, the largest share of 26.71% of the total, and those connected with the teacher at 56, the third largest share of 20.58% of the total.

If viewed more closely, it can be seen that the total number of conflict resolutions decreases from 66 for $C3_1$ through 57 for $C3_2$ to 49 for $C3_3$, a clear indication that changes in conceptualization are much more difficult than changes in skills and knowledge and are less easily reached. Figures in the brackets strongly suggest that intrapersonal cognitive development are heavily tipped towards the preliminary stage (18 C1s out of the 72 total) and changes in knowledge (35 $C3_1$ against 5 $C3_2$ and 8 $C3_2$s). However, the situation with social cognitive conflicts is quite different. Social cognitive conflicts connected with the class mode and the teacher are heavily tipped towards changes in skills (23 $C3_2$ s against 9 $C3_1$ s and 12 $C3_2$s for Class Mode, 20 $C3_2$ s against 10 $C3_1$ and s 8 $C3_2$s for Teacher) and those connected with collaborative construction, events in and out of class are tipped towards changes in conceptualization (4 $C3_3$ s against 1 $C3_1$ and 2 $C3_2$s for Collaborative Construction, 8 $C3_3$s against 3 $C3_1$s and 1 $C3_2$ for Event In, and 9 $C3_3$ s against 8 $C3_1$ s and 6 $C3_2$s for Event Out) .

The figures concerning negative resolutions like rejection, reinterpretation, exclusion, uncertainty are 0 for Reading, 11 for Class Mode, 2 for Events In and 1 for the three categories of Teacher, Collaborative Construction and Events Out. It suggests that negative resolutions are more likely to appear in social cognitive conflicts than in intrapersonal cognitive conflicts and there seems to some intrinsical relationship between $C3_0$ and the other types of conflict resolutions.

Table 6: Correlations among Types of Cognitive Conflict Resolution

Correlations

		$C3_0$	$C3_1$	$C3_2$	$C3_3$
$C3_0$	Pearson Correlation	1	-.189	.282	.515[**]
	Sig. (2-tailed)		.317	.131	.004
	N	30	30	30	30

**. Correlation is significant at the 0.01 level (2-tailed).

Table 6 shows that the correlation between negative resolution and changes in conceptualization is .515, that is, significant below the . 005 level.

WORD ASSOCIATION ANALYSIS

Word association analysis starts with a structural reconstruction based on frequency and mean rank or rank average. In our word association test, each student was required to write down 10 associated words to the stimulus term 思考(thinking or reasoning) and the expected number of associates given by the 33 participants is 330. Frequency means the number of identical associates found in the general pool of the associates given by all participants returning the data, that is, the frequency of a word appearing in the general pool. The higher is the frequency of an associated word appearing the pool of data, the more important is the associated word to the stimulus term and the closer is its position to the core of the social representation of the stimulus term. Rank is closely related with the order of emergency of the associate to the mind of the participant as he or she was trying to respond to the stimulus word consecutively. Since 10 associations were required for the stimulus word, the highest possible rank for each associate is 1 and the lowest possible rank is 10, indicating that the former is written down earlier than the latter in the association test and stands closer to the stimulus word in the semantic network. Therefore, we say that the smaller is the figure of the rank, the closer it is to the core. To facilitate the structural reconstruction of the data, values are assigned to the ten possible ranks, ranging from1.1 to 1.9. Mean rank is the result of summing up all the rank values of the associated word appearing in the total pool and then dividing the total figure by its frequency. Table X takes 反思(reflective thinking), one of the associated words, as an example to illustrate the two statistical dimensions of the coming structural construction.

Table 7: Statistical Dimensions for the Structural Construction

rank	1	2	3	4	5	6	7	8	9	10	frequency	Mean rank
value	1	1.1	1.2	1.3	1.4	1.5	1.6	1.7	1.8	1.9		
反思	3	0	1	0	1	0	1	0	0	0	6	1.2

Hierarchical Clustering analysis based on frequency and mean rank is applied for a structural construction of the word association data.

Table 8. Structural Construction of the Word Association Data

Stimulus word	思考 thinking	Required number of associates from each participant							10	
Participants Returning data	33/pretest 33/posttest	Expected number of total associates							330	
		Frequency		Number of associates		Percentage		words		Percentage	
Cluster		Pre	Post	Pre	Post	Pre	Post	Pre	Post	Pre	Post
1		8	8	8	16	2.42%	4.84%	1	2	0.47%	0.83%
2		7	6	28	12	8.48%	3.64%	4	2	1.86%	0.83%
3		5	4-3	15	44	4.55%	13.33%	3	14	1.40%	5.79%
4		4-3	2	59	68	17.88%	20.61%	18	34	8.37%	14.05%
5		2-1	1	220	190	66.67%	57.58%	189	190	87.9%	78.5%
Total				330	330	100%	100%	215	242	100%	100%

All the associates in the sample are organized into 5 clusters, Clusters 1 and 2 forming the central core of the social representation of the stimulus word "思考", Cluster 5 forming the periphery, and Clusters 3 and 4 forming the transition from the periphery to the core. The total number of words is 215 for the pretest, and 242 for the post-test, indicating that the posttest social representation has a larger spread than the prestest

one. The central core is composed of 5 words for the pretest, 10.9 % of the total of 330 associates, and only 2.33% of the total of 215 words. For the posttest, the core is made up of 4 words, 8.28% of the total of the associates and 1.66% of the total of 242 words. This indicates that the pretest social representation has a thicker core than the posttest one. The transitional part is composed of 21 words for the pretest, 22.33% of the associates and 9.77% of the 215 words, and the figures for the posttest are 48 words, 33.94% of the associated and 19.84% of the 242 words, indicating that the posttest social representation has a larger transitional section. Figures in Cluster 5 are 189 words for the pretest, 66.67% of the associates and 87.9% of the 215words, and those for the posttest are 190 words, 57.58% of the associates and 78.5% of the 242 words, indicating a proportionally much smaller periphery.

The structural construction provides a typological information to anchor the position of each associate in the social representation of the stimulus word. By analyzing the components of the central cores of the pretest social representation and the posttest one and by tracing the movement of each of the associated words among the clusters, we hope to detect evidences for qualitative changes in the shared mental model of the stimulus word "思考"

Table 9: The Central Cores of the Pretest and Posttest Social Representations of 思考

Pretest Core	Cluster	Posttest Core	Cluster
1*:进步progress	1	1:人生 human life	1
2:哲学 philosophy	2	2:进步 progress	1
3:安静quiet	2	3:哲学philosophy	2
4:人生 human life	2	4:反思reflection	2
5:问题 problem	2		

 * The number indicates the serial position of the word appearing in the data pool.

The pretest core has 5 words and the posttest 4, and of these 9, 2 are shared and located in the original clusters : "progress" in Cluster 1, "philosophy" in Cluster 2; 1 is shared but located in different clusters: "human life" in Cluster 2 in pretest and in Cluster 1 in posttest; 2 words, that is, "quiet" and "problem" in the pretest are dropped down into Cluster 3 in the posttest and the word "reflection" is added, or moved from Cluster 4 (see Table X) in the pretest to Cluster 2 in the posttest. It is quite reasonable to find "progress" and "philosophy" at the pretest and posttest cores as the former might be regarded as the purpose of thinking and the latter as the science or methodology of thinking. The movement of "human life" into Cluster 1 shows its greater importance in the posttest social representation and indicates a greater awareness of the fundamental function of thinking : not only for progress in general, but for the promotion and enrichment of our life as a human being.

The examination of the central cores shows that there are upward movements (going towards the core) and downward movements (going towards the periphery) in the posttest social representation which can be used to show the changes the representation has undergone. Yet as the space is limited, our focus will be directed to the upward movement in and new additions to the posttest representation.

Table 10: Upward Moving Words in the Posttest Social Representations

Pre	Cluster	Post	Cluster
4:人生 life	2	1:人生life	1
13:未来 future	4	6:未来future	3
56:梦想 dream	5	30:梦想dream	4
109:家庭family	5	37:家庭family	4
155:爱情love	5	52:爱情love	4
24:反思reflection	4	4:反思reflection	2
40:沉思mediation	5	17:沉思mediation	3
9:理性 reason	4	13:理性reason	3
11:学习learning	4	7:学习learning	3
206:联想association	5	32:联想association	4
107:关系 relation	5	41:关系 relation	4
98:学问 knowledge	5	20:学问knowledge	4
163:认真earnest	5	26:认真earnest	4
19:习惯habit	4	9:习惯habit	3
130:过去bygone	5	40:过去bygone	4
171:肤superficial	5	42:肤浅 superficial	4
118:想着怎样改变自己 thinking how to change myself	5	15:改变 change	3
14:实践practice	4	12:实践 practice	3
54:痛苦 pain	5	11:痛苦pain	3
43:总结 conclusion	5	5:总结conclusion	3
174:交流communicate	5	36:交流communicate	4
12:创新innovation	4	16:创新 innovation	3
103:创造creation	5	48:创造 creation	4
162:启发inspiration	5	28:启发inspiration	4
45:琢磨ponder	5	19:琢磨ponder	4
173:火花 sparkle	5	39:火花sparkle	4

As shown in Table 10, words moving towards the core in the posttest are semantically related to four domains: a) the domain of life, future, and dream; b) the domain of reason, learning and reflection; c) the domain of action, change, and self-surpassing; d) the domain of inspiration, innovation, and creation.

These tendencies are greatly reinforced by newly added words in the posttest representation. The domain of life, future, and dream is expanded by words like "growth" in Cluster 4, "soul", "heart", "wisdom", "beauty", "nature" , "rainbow" and "sky-watching" in Cluster 5; the domain of reason, learning and reflection is enriched by words like "understanding", " insight", "discover" in Cluster 4,"logic", "analysis", "fantasies" and "discretion" in Cluster 5; the domain of action, change, and self-surpassing is emotionly packed by words like "initiative", "action", "exploration","lesson" and "experience" in Cluster 4, "disorientation", "courage", "undergoing", "setback", and "power" in Cluster 5; the domain of inspiration, innovation, and creation is developed by words like "sublimation " in Cluster 4, "deconstruction", and "transcendance" in Cluster 5.

CONCLUSION

Findings in the present study vindicates the central role of cognitive conflicts in cognitive development. Firstly, the construction of concept mapping, by shaping vague ideas into clear-cut diagrams, helps to detect cognitively anomalous data and create a demand to re-examine step by step existing beliefs in the light of incompatible ideas shown in the mapping. It provides an opportunity for collaborative reconstruction through questions and explanations and helps to bring implicit intrapersonal conflicts as stimuli leading to social cognitive conflicts. Secondly, intrapersonal cognitive conflicts are less likely to result in negative resolutions and more likely to bring about changes in knowledge than changes in skills and conceptualization, while social cognitive conflicts are more likely to result in negative resolutions at the beginning and, if lasting long enough, are more likely to bring about changes in skills and ways of conceptualization. Thirdly，continuous social cognitive conflicts produce long-term effect by changing the social representation of key ideas in our mental model, reinforcing certain dimensions both in the central core and the periphery, and even adding new dimensions to them.

256 - A Zimbabwean Chemistry Teacher's Practices and Beliefs about the Teaching and Learning of Stoichiometry Concepts at Ordinary Level

Vongai Mkazho Mpofu

Bindura University of Science Education, Zimbabwe
vmpofu64@yahoo.com , vmpofu@buse.ac.zw

Abstract: This is a naturalistic classroom-based exploratory study of the kinds of beliefs held by a chemistry teacher about the teaching and learning of stoichiometry concepts. The variations of these beliefs with the teaching of different stoichiometry concepts are also revealed. A teacher stationed at a well established and resourced urban school in Zimbabwe was purposively sampled to participate in this study. Data was generated from documents, video recorded lesson observations and tape recorded belief interviews. Data interpretation involved the in-field and post-field stages. Data collected was continuously interpreted through a constant comparative technique to establish evaluative patterns which guided the data generating process. Text analysis by means of grounded theory techniques was employed to interpret data in the post-field stage. Major themes were developed by merging identified ideas and sub themes as suggested by the data. Findings are presented in a narrative form supported by charts and exemplary field notes, interview and observation transcript excerpts. The teacher's personal beliefs that guide his stoichiometry instruction fall into four emergent categories: objectives of teaching, learning conceptualisation, the perceived complexity of concept and mathematical reasoning application. Slight variations of the beliefs with the concepts taught are revealed. The teacher's beliefs about stoichiometry concepts teaching and learning are mostly traditionally oriented. His teaching of stoichiometry concepts is typically teacher-centered and text-book based. The teacher's self-reliance teaching approach, learning and teaching stoichiometry experiences seem to have influence upon these beliefs. This study gives insights into the interactions between beliefs and teaching practices and recommends further research on the topic with a larger sample of participants in different contexts.

Key words: ordinary level, stoichiometry concepts, teacher's beliefs**,**

INTRODUCTION

Much has been written about the complexity of chemistry and the difficulties students encounter in understanding its concepts (Gabel, 1998; Calyk**,** Ayas & Ebenezer, 2005). Chemistry concepts are allied and the subsequent understanding of build-up concepts depends on prior conceptions (Schmidt, 1997). Conceptions deviant from the existing chemistry ideas and explanations are called misconceptions. Okanlawon (2010) concurs with this view in his contention that misconceptions are learners' understanding of scientific concepts that are at variance with accepted scientific views regardless of their sources. Misconceptions act as barriers to further chemistry learning (BouJaoude, 1994; Mas, Perez and Harris, 1987). This effect has been widely studied and found to be persistent in the context of chemistry education research (Bradley, Berrans & Long, 1990; Garnett, Garnett & Hackling, 1995; Treagust, Chittleborough, & Mamiala, 2003; Mpofu, Kusure, & Zishura, 2008).

Stoichiometry is a fundamental, universal and central topic to all chemistry branches **(**Yalcinalp, Geban, & Ozkan 1995, Schmidt & Jigneus, 2003; Evans, Leinhardt, Karabinos, & Yaron, 2006, Chanyah & Coll, 2007). Stoichiometry quantifies reactants and products of a chemical reaction (Dennistron, 2001; Okanlawon, 2010). Consequently, understanding stoichiometric concepts demand both conceptual and mathematical reasoning (Bennert & Agarkar, 2003). Solution chemistry, acids and bases, electrochemistry, bonding and chemical equilibrium exemplify some of the topics which demand a good grasp of stoichiometry concepts. This explains the worldwide attention it has received in chemistry education research and the secondary school curriculum. Nonetheless, much of stoichiometry research is oriented towards its learning and the learners' conception problems. The focus of this study is on the teaching of stoichiometry to inform the development of any intervention strategies aimed at overcoming difficulties students experience in grasping stoichiometry concepts.

Literature is rich on the difficult nature of the stoichiometry topic studies (Yalcinalp, et.al, 1995; Heron & Greenbowe, 1996; Schmidt et al, 2003; Kolobe, 2007; Evans,Yaron, & Leinhardt, 2008). A myriad of studies revealing that learners bring a surfeit of misconceptions to the study of stoichiometry also exist (Woods, 1990; BouJaoude Barakat, 2000; Furio, Azcona, & Guisasola, 2002, Fach, de Boer, & Parchmann, 2007).

This exacerbates the snag learners have in comprehending its concepts. It is worrisome that the intensive research into chemistry learning has not brought much change into the learning of chemistry. An equally vast study on teaching shows that the practice teaching in science classrooms is not changing (e.g. Johnston, 1997; Smerdon & Burkam, 1999; Hobden, 2005) and is predominantly traditionally oriented. To me this is evidence that research into the learning of chemistry has been an isolated process from that of its teaching. My logical thinking is that such secluded research remains informative without bringing much change to the teaching and learning chemistry prominence has largely contributed to the non-productive learning and teaching of chemistry in general and in particular stoichiometry.

This paper proposes a holistic chemistry education research approach. I view this research orientation as a possible solution to the transformation in the teaching and the consequential conceptual understanding of stoichiometry concepts. The argument in this paper is that the teacher is a key person to the effective learning of any concept. He/she has classroom practice autonomy in that s/he is mostly in control of learning factors such as aids, strategies, and content depth coverage. He/she selects teaching methods which he/she regards as appropriate for the effective transformation of content to the learners. Notably, the teacher's classroom practices and what s/he considers to be effective teaching is not always compatible with effective teaching for authentic learning. Shulman (1987), Baumert and Kunter (2006) agree that the teacher's effectiveness depends on professional competence. In an effort to understand factors which influence professional competence, many researchers have focused on the knowledge that teachers create by transforming their content into a teachable form which Schulman (1986) names Pedagogical Content Knowledge (PCK). To date the Schulman ideas on PCK have metamorphosised. For example, Rollnick, Bennett, Rhemtula, Darsey and Ndlovu (2008) have developed a PCK model (Figure 1, appendix 1) in which teachers' beliefs anchor the Teacher's Knowledge Domains (TKD). Four distinct kinds of knowledge make up TDK and integrate to produce PCK which is noticeable through observable classroom practice indicators called manifestations of teacher knowledge (MTK). MTK aspects include representations made by the teacher, including metaphors and illustrations; curricula saliency (depth of coverage, what to leave out and what to teach); assessment and topic specific instructional strategies. These are referred to as manifestations of PCK in the model. Rollnick et al's (2008) view PCK as how teachers teach their subject by accessing what they know about the subject, the learners they are teaching, the curriculum with which they are working and, what they believe counts as good teaching in their context. Undoubtedly, teachers' classroom practices are greatly influenced by his/her beliefs (Clark & Peterson, 1986).

Beliefs play a crucial role in defining personal behavior and in organizing knowledge and information. Research has shown that beliefs are relevant to the enhancement of professional competence which in turn results in improvement and effectiveness of schools. Koballa, Gräber, Coleman, and Kemp (2000) conclude that beliefs influence all types of interactions between teachers and pupils. Accordingly, the knowledge about teachers` beliefs is crucial when attempting to affect teachers' actions (Ben-Peretz, 1984; Fischer, 2000). The argument in this paper is that the starting point to overcoming what research has not unravelled about teachers' and students' difficulties in teaching and learning stoichiometry concepts is to examine the prevalence of certain beliefs in relationship to stoichiometry specific TDK and MTK. This fills the research gap which TALIS's (2009) notes has little research on beliefs and practices specific to certain subjects in their examination of a variety of beliefs, practices and attitudes. The TALIS (2009) model (Figure 2: Appendix 2) is used to explore the teachers' beliefs and practices.

This case study explores teachers' beliefs and practices about stoichiometry teaching and learning, and is guided by the following research questions:
1. What beliefs are held by the teacher about the teaching and learning of stoichiometry?
2. How do these beliefs vary with chemistry concepts taught?
3. How do the teachers' beliefs influence his classroom practice?

METHODOLOGY

A case study design of the qualitative approach was used. Keeves (2004) asserts that the qualitative paradigm seeks to understand motives behind human reactions and therefore this approach is suitable for the unveiling of belief factors on stoichiometry specific TDK and MTK. The approach guided the researcher in the examination of beliefs and practices phenomena in a naturalistic and interpretive way. A single person case study methodology was adopted in this research in view of a unit of the analysis that is characteristic of a case study design. The case study definition of a person, a small group, a single situation, or a specific "case," justifies the one participant approach. The one participant case was chosen also on the basis of Keeve's (2004) heed on the cost and resource constraints that limit the amount of data generated associated with a multi case research approach. This case study was conducted for exploratory reasons as a prelude to

social research (Yin, 2003) to provide insights into stoichiometric specific teaching and learning beliefs and practices. Furthermore, the case study design allowed details of the phenomenon to be brought from the viewpoint of the participant within nested contexts using multiple sources of data.

The unit of analysis whose phenomenon is examined from a multi-perspective is a critical factor in a case study (Tellis, 1997.) To ensure fulfilment of this case study element the participating teacher was purposively sampled. The logic of purposive sampling is to select cases that are likely to be information rich, with respect to the purpose of the study (Creswell, 2007). An experience of five or more years of chemistry teaching, located at well resourced school and voluntary informed consent to participant in the study was the sampling criteria. The chemistry teacher is pseudo named Happy for identity confidentiality in line with ethical research issues. Happy is stationed at trustee school referred in this research as Northgate.

The research data was triangulated and generated from documents, lessons and interviews. Cohen and Marion (2000) define triangulation as the use of two or more methods of data collection in the study of some aspect of human behaviour. The three methods of data generation employed were considered sufficient for the rationale of triangulation described by Creswell (2007) as complementary, corroborative and confirmatory. According to Tellis (1997) the need for triangulation arises from the ethical need to produce plausible study findings. The teacher was observed teaching twenty four form-3 chemistry stoichiometry lessons. The teacher was interviewed before and after each week's lessons. This gave a total of eight interviews. The lessons were double periods of seventy minutes each. The interviews on average lasted between 15 to 20 minutes. The lesson observations and interviews were field-note captured and enriched by video and audio tape respectively. Transcripts and field notes were infield data interpreted on a daily basis through a constant comparative technique to guide on when to use documents and what to look for. Teacher resources and generated documents such as textbooks, teaching materials, past exam papers, scheme books, record of marks, pupils' exercise books and written work items used in preparing lessons were interpreted mostly before the pre-observation interview as and when the situation demanded. Field notes were used to capture document analysis and general observation data. The three sets of data to emerge from the documents were field notes data (FND), Lesson Observation data (LOD) and belief Interview Data (BID).

Text analysis by means of grounded theory (GT) techniques was employed to merge and interpret FND, LOD and BID in the post-field stage. Emerging ideas, sub themes and major themes of data categories were established and organized from GT data analysis (Markic et al., 2008) as guided by identified MTK and belief constructivist and traditionalist categories in Appendix 1, Figure 1 and figure 2 respectively. Units of ideas were counted to give the sum total of ideas (N). These were grouped into categories of sub and major themes respectively. The findings are presented in a descriptive form supported by some descriptive statistics and direct extracts from field notes and interview transcripts.

RESULTS

The findings of this study which answer the research questions stated earlier are presented in the ensuing sections.

Happy and his operational nested contexts

Teachers operate in a. The ensuing section describes Happy's characteristics, his operating environment and how it influences his teaching practice. Happy has been teaching chemistry as a stand alone subject or in combination with physics (physical science) at ordinary level in different schools for the past seventeen years. He holds a Bachelor of Education degree in the area of chemistry after a post 'O' level certificate in education at secondary school level. Happy does not belong to any association of science teachers and never attends any meetings called for by chemistry clusters in the district. He taught all his chemistry lessons during the period of research. He has been stationed at Northgate High School for the past seven years. Northgate is an 'A' level co- educational school that is located in an urban low density suburb in one of the large cities of Zimbabwe. The school is well established, well resourced and academically reputable. At the time of this research Happy was teaching one form 2 general science class, one form 3 chemistry class and one form 5 chemistry class. The total teaching load was 22 periods per week. The form 3 class of 30 pupils had 6 chemistry lessons per week and followed the ordinary level chemistry syllabus (5071). The class has its lessons in a well equipped chemistry laboratory with a lecture section on one end.

For the past twelve years, Happy has consistently produced good results in chemistry at both 'O' and 'A' level with average pass rates of 90% and 96% respectively. He uses English for instruction. Happy's chemistry teaching falls within a nested context environment, which starts with the classroom environment level. It then interacts with outer and higher level environments, which are; the department of science, other departments in the school, the school location, the ministry and the nation of Zimbabwe at large i.e. business, industry and society in general. This means his classroom practices are indirectly or directly influenced by

both the macro and micro environmental level factors as depicted in figure 2, appendix 1. His beliefs about stoichiometry teaching reflect his TDK and influence his practices as indicated by MTK as he operates in his nested context environment.

Emerging Belief categories

The personal beliefs that guide Happy's stoichiometry instruction fall into four categories These categories are identified as objectives of teaching (OOT), perceived conceptualisation of learning (COL), complexity of concept (COC) and mathematical reasoning application (MRA). These belief categories were interpreted on a continuum from traditional to modern beliefs as postulated by Markic (2008) in Markic and Eilks (2008). Figure 3 shows that a major proportion of Happy's belief's about teaching and learning stoichiometry contributes to the OOT and COL categories, which is approximately 65%. His teaching of stoichiometry concepts in any of the belief categories is focussed towards recall of facts, symbols, formulae and step by step procedure of balancing of chemical equations and solving of stoichiometric problems respectively as evidenced in his overall stoichiometry teaching strategy in Appendix 2, Figure 4.
Figure 3: Stoichiometry Teaching and Learning beliefs

The results in Figure 3 also show that Happy holds both the constructivist and traditional beliefs about the teaching and learning of stoichiometry. The traditional beliefs override the constructivist beliefs.

Mr. Happy's overall strategy in his stoichiometry lessons is based on his perception of the complexity of concepts developed, how best his pupils learn the concepts and his past experiences of teaching the topic. The strategy is constructed from his work preparation (scheme of work) and topic lesson delivery during lesson observations. Happy confirmed the strategy in one of the belief interviews when he said:

> Teaching from the language to solving stoichiometric problems is the best approach I have learnt to use over the years. …..many of my pupils experience problems with this topic no matter how intelligent they are, so I have to go over and over again until they get used to the difficult ideas.

Happy's objectives of teaching stoichiometry

Mr. Happy's objectives of teaching stoichiometry are examination driven. He is obsessed by the idea of maintaining a high public examination pass rate and his reputation as a good chemistry teacher. His classroom activities are mostly teacher directed, controlled and dominated (Figure 5).
Figure 5: Happy's main classroom activities time proportion

The time he spends on a particular aspect of the stoichiometry topic is determined by its frequency of appearance in public examinations and how it affects the understanding of subsequent topics e.g. kinetic theory, chemical reactions, chemical energetics, acids and bases, and practical chemistry topics. Happy acknowledges that he takes his time to explain the mole concept and on a step by step basis, carry out calculations and determine the formulae of compounds for the reasons summarised in one of his interview responses:

I devote my time to formula determination, balancing of equations and stoichiometric calculations in relation to the mole concept. The mole concept is a very difficult topic. My pupils have always gained understanding of this difficult concept through practice with problems from text books and past examination papers. …. Textbooks are not a problem here and I photocopy past examination papers for them to use during practice. They have no way out except to understand the concepts for further use in the topics I will cover next. This is good preparation for examinations.

The follow

Magnesium Oxide is produced by burning oxygen as shown in the equation below

$$Mg \quad + \quad O_2 \quad \longrightarrow \quad MgO$$
What mass of Mg is needed to produce 0,5g of MgO?

Step 1: Balance the equation if it is not balanced
Step 2: Highlight the substances involved from the question
Step 3: Write down the relative masses under each of the substances involved
Step 4: Establish the stoichiometric relationship
Step 5: Construct the arithmetic problem and solve it

Solution

$$2Mg_s \quad + \quad O_{2g} \quad \longrightarrow \quad 2MgO_s$$

24   40

?   0,5g

1149
Stoichiometric relationship is established by looking at the ratio of the number of moles of each of the involved substances
Then you circle them as shown

The mole ratio of Mg and MgO is 1:1 i.e. n(Mg)= n(MgO)
Where n is number of moles.
Therefore, number of moles (n) = mass (m)/ Molar mass (M)
Therefore the arithmetic problem to solve is
m(Mg)/M(Mg) = m(MgO)/M(MgO)
and start by making mass of Mg the subject of the formula
m(Mg) = m(MgO)/M(MgO) x m(Mg),
Substite the formula and/or symbols with the value for its amount
That is, [(0.5/40) x 24]g   = 0.3g

Happy deliberately omits some aspect of stoichiometry which I consider necessary for conceptual understanding. For example, he only mentions atoms and ions under the term particle leaving out molecules. The Avogadro concept is not clearly linked to the different types of particles. His position is that a holistic approach to the term particle will confuse his pupils. To him what is important is to remember the Avogadro constant and use it in calculations.

Happy's conceptualization of learning of the stoichiometry concept
Thirty five percent (35%) of emergent ideas about Happy's beliefs of stoichiometry learning and teaching fall within the COL category. Happy's beliefs about stoichiometry learning are traditionally inclined. He considers memorisation of definitions and the procedural aspects of stoichiometry as significant to learning of its concepts. He employs algorithmic and pneumonic approaches in his overall stoichiometry teaching strategy. As he teaches, he makes reference to the memorisation learning strategies of his days that gave him clues to remember some stoichiometry and chemistry concepts. For examples in one of he lessons he said:

> Formula determination is not all that easy. You need a lot of practice; however for those which occur regularly in examinations I tell my students to remember them. Such as,

His overall teaching strategy evidences some constructivist belief of learning stoichiometric approach. It is a prior knowledge build-up approach which shows linkage of concepts. However, his classroom practises to deliver the concepts are traditional belief based as depicted in figure 5. Mr. Happy's use of the language of chemistry without code switching as well as the non use of analogies is depicted in lesson observation and preparatory work. His reasons for the approach confirm he perceives memorisation and procedural learning as a crucial approach to learning. This provides an answer to his step by step approach to teaching. Mr. Happy said:

> I use stoichiometry language and not English in my teaching, to familiarise my pupils with them. Understanding of the language means understanding of what is taught. Analogies make things worse. I call a spade a spade. Either you get it or you miss it. But with time I make sure we are together. I do not associate myself with failures.

Happy's perceived complexity of concept
Mr. Happy's procedural stoichiometry learning conception is linked to his stoichiometry complexity view. In the interviews he consistently highlights that pupils experience difficulties in comprehending the mole concept, interpretations of symbols, formulae and equations and solving stoichiometric problems. He attributes stoichiometry learning difficulties experienced by his pupils to the nature of the topic. His emphasis is on getting used to the approach to teaching the concepts. His view of symbols and formulae as key aspects to the understanding of the topic emerged from his lessons and was confirmed in fieldnotes and interview excerpts. In the fieldnotes summarising observed lessons I wrote:

> In every lesson Mr. Happy places great emphasis on symbols and formula and their consequential effect on understanding of concepts covered in other aspects of the topic. He showed how symbols and formula are interpreted as and when he felt an opportunity has prevailed itself in all his lessons.

Mr. Happy confirmed this observation in one of the interviews as presented in the following excerpt.

> I call it a wake up tablet when I remind my pupils about symbol and formulae in almost every chemistry lessons. Chemistry is about these. You get it.

Happy's perceived stoichiometry learning mathematical reasoning application.
Mr. Happy's perceptions about mathematical reasoning application to the learning of stoichiometry are captured in the following interview excerpt.

> In my teaching of stoichiometry, I have noticed that many pupils have difficulties in understanding the thought processes involved to solve stoichiometry problems. Pupils in the chemistry class are good in mathematics. But though mathematics is applied in learning stoichiometry most of my pupils do not display the level of mathematical reasoning required in solving these problems. ……….My teaching caters for pupils with mathematical reasoning problems and gives advantage to those with it. So by the end of the lessons with or without mathematical reasoning all my pupils will correctly solve stoichiometric problems.

In follow-up interviews to probe Mr. Happy's mathematical reason application in teaching and learning stoichiometry beliefs, it became evident that he holds constructivist beliefs. He identified the standard form, mathematical operations, co-efficient, bases and change of subject in a formula as important in solving stoichiometric problems. He illustrated this argument with the Avogadro constant expression 6.02×10^{23} particles from the standard form $A \times 10^n$ and said:

> An understanding that n takes integer values only and A takes values between 1 – 10 helps the pupils to understand the calculations and check the answers. The base form view of the expression helps the student to understand the mole concept and express the amount of substance in various forms such as grams, moles, number of particles.

However, his emphasis on procedural learning of the aspects of stoichiometric is supported by his belief in teaching for external examination assessment objective. For example, the mole concept requires pupils to use the idea of amount of substance in calculations rather than conceptualise it. The traditional belief he holds in the teaching and learning stoichiometry aspects overrides the constructivist ones as depicted in figure 6. The major aspects captured in figure 6 are: Terms (T), Atoms, Elements & Symbols (AES), Compounds and Formula (CF), Reactions and Equations (RE) and Stoichiometry Calculations (SC).
Figure 6: Stoichiometry aspects belief variations

SUMMARY, CONCLUSION AND IMPLICATION

To answer research questions 1 and 2, Mr. Happy holds both constructivist and traditional beliefs about teaching and learning of stoichiometry but the traditional beliefs override the constructivist ones. The findings also show that his self reliant and textbook based teaching of stoichiometry classrooms practices are teacher-centered, examination driven and traditionally-held beliefs oriented based addresses question 3.

The finding that Happy hold traditional oriented beliefs about stoichiometry teaching and learning is in line with Markic and Eilks's (2008) finding from their study on German first year chemistry student teachers' beliefs about chemistry teaching. Though this finding reflects the German context qualitative research authorities contend that readers can transfer such findings to other contexts. The findings from the two studies differ in that Mr. Happy is a qualified and experienced teacher whilst the German study participants were student teachers. Markic and Eilks (2008) also revealed that the middle and completing university teacher training programs student teachers have more modern (constructivist) beliefs about teaching and learning chemistry. This points out that professional development training plays a significant role in modifying teachers' beliefs. Therefore, chemistry teacher education departments and educators should incorporate in their programmes modern theories teaching and use them in their teaching to orient teachers` belief structure towards progressive teaching.

Happy's traditional belief orientation in his stoichiometry teaching may have stemmed from his school experiences (Calderhead and Robson, 1991 in Markic and Eilks, 2008) and teacher qualification training. His practice of teaching may remain static in as long as he continues not to participate in outside school academic activities. His traditional beliefs are also in large emanating from his teaching for examination focus. Markic and Elkis's (2008) concluded that the student teacher's exposure to the reality of the teaching career moves their beliefs slightly back towards a more traditional style. This confirms and provides a possible explanation to the beliefs Mr. Happy's holds. After training teaching experience seems to orient teachers' beliefs in the other direction, in the case of this study towards traditional beliefs. Therefore, Chemistry educators systems, with particular reference to Zimbabwe need to form an active chemistry education association for research and staff development activities. These may assist in modification of teachers' beliefs about teaching and learning.

The finding that Mr. Happy posses both constructivist and traditional beliefs about the teaching and learning stoichiometry is encouraging to any intervention strategies aimed transforming his teaching practices. Mr. Happy's traditional beliefs seem to be supported by the assessment system and his isolated teaching. Exposing him to in-service training seminars, research and activities and introducing a supportive examination system may have positive influence upon his beliefs.

My main concern as a chemistry educator is to search for efficient and pleasant ways of communicating chemistry concepts to learners at any level. One way to accomplish this is to facilitate positive change in the teacher's beliefs in view of the contention of by many researchers that changes in teacher's practices are often a result of changes in their beliefs. This study gives insight into the beliefs and teaching practices interactions and recommends further research on the topic with a larger sample of participant in different contexts.

Abstract: This empirical study explores the conceptions of young Spanish secondary students´ on citizenship. A questionnaire was applied to a sample of 2261 students of different grades (2º and 4º) of Secondary School that were studying in three autonomous regions: Madrid, Basque Country and Extremadura. The questionnaire was designed by different experts in citizenship education, and developmental and educational psychology. Each of the questions included in the questionnaire dealt with different aspects related with a set of dimensions which are essential to take into account in the process of developing and understanding a cosmopolitan citizenship. These dimensions were: democracy, diversity, globalization, sustainable development, empire, imperialism, power, prejudice, discrimination, racism, migration and human rights.The results indicate that the citizenship questionnaire is reliable and valid. With regard student´s conceptions of citizenship, results indicate that students show a trend that ranges from a more traditional conception of citizenship and human rights towards a more global and cosmopolitan one. There were differences between the conceptions of citizenship and human rights by grade and age. There were also differences by gender, type of school and students´ socio-cultural background. In the group of foreign students there were no significant differences.

Keywords: citizenship education, teaching and learning, cosmopolitan citizenship, globalization, social justice, human rights, secondary education, student´s conceptions.

INTRODUCTION

Over the last decades there have been a number of studies conducted on education for citizenship and human rights from different perspectives. One of the most representative works in this field is the "Civic Education Study" (CIVED), coordinated by the International Association for the Evaluation of Educational Outcomes (IEA), in which 28 countries had participated with the objective of making an assessment of adolescents´ civic knowledge and attitudes (Torney-Purta & Barber, 2005).

Moreover, other studies have focused on the conceptual discussion about citizenship and the educational approaches related to citizenship education (e.g. Argibay, Celorio & Celorio, 2009; Cabrera, Marin, Rodriguez & Espin, 2005, Crick 2007, Crick, 2008; Maiztegui, 2007, Trotta, Jacott & Lundgren, 2008; Velásquez, 2005; Youniss, & Hart, 2005). Also, other studies have addressed important aspects such as those related to the learning and teaching about citizenship and human rights issues (e.g. Akar, 2007; Alviar-Martin et al., 2007; Davies, Fülöp & Navarro, 2007; Flanagan, Gill, Cumsille & Gallay, 2007; Haste & Hogan, 2006; Navarro, Jacott & Maiztegui, 2011; Sim, 2008; Tourney-Purta & Barber, 2005), or with the different spaces and contexts in which education and training for citizenship takes place (Agra, 2008; Jacott et al., 2008; Moran, 2007). Nevertheless, there are very few studies devoted to analyze how young people understand citizenship (e.g. Lister, Smith, Middleton, & Cox, 2003; Osler & Starkey, 2003; Torney-Purta & Barber, 2005).

Thus, this study seeks to explore the student´s conceptions of citizenship in secondary schools of different Spanish regions: Madrid, Extremadura and the Basque Country. Specifically, our objective was to analyze to what extent students of different educational levels tend to have a more traditional conception of citizenship or a more cosmopolitan conception of citizenship and human rights, based on the work done by authors such as Banks et al (2005), Nussbaum (1999) and Osler and Starkey (2003).

METHOD

Design of the questionnaire
The questionnaire was constructed by different experts from a set of dimensions proposed by Banks et al. (2005) and Osler and Starkey (2003, 2005), which are essential to take into account in the process of human rights education and cosmopolitan citizenship, to namely: Democracy, Diversity, Globalization, Sustainable Development, Empire, imperialism, power, Prejudice, Discrimination, Racism, Migration and Human Rights.
The final questionnaire consisted of 30 questions whose structure consisted of a statement and three possible answers. The statement posed a hypothetical situation, although possible in reality, which contained important elements or different relationships with some crucial aspect of the dimensions. Response options consisted in three alternative responses to each hypothetical situation described, in which each participant had to select the one response that was the most consistent for him or her. In order to analyze the student´s responses, these three response options were given different values, depending if they were more related to a more traditional conception of citizenship or to a more cosmopolitan conception of citizenship and human rights.

Participants
The questionnaire was administered to a sample of 2261 students from different educational levels of compulsory secondary education (2nd and 4th grade), which belong to different public schools and private schools from different Spanish regions: Madrid, Extremadura and the Basque Country. The distribution of participants by age group can be found in Table 1.

Table 1: Sample distribution of participants by age

Age	Frequency	Percentage
13	384	17,0
14	633	28,0
15	472	20,9
16	592	26,2
$\geq$17	180	7,9
Total	2261	100,0

As it can be observed, the highest percentage of students is between 13 and 16 years of age. Within this age range is primarily the student population of 2nd and 4th grades of compulsory secondary education in Spain. With regard to type of school, it can be seen that 54.3% of students attend public schools, compared with 41.7% of students attending private schools.

RESULTS

In order to identify the conceptions that students had with regard to citizenship and human rights, the rating used in this study was based on the skill level obtained from the Rasch model. Thus, for purposes of analysis and interpretation of the results, the data obtained were divided into different ranges according to the quartiles of the distribution of the sample; forming four groups (see Figure 1).
The first group (q1) brings together students who have chosen response options that are closer to a conception of cosmopolitan citizenship, the second group (q2) brings together students whose answers tend toward a cosmopolitan conception, and third group (q3) brings together students who show a tendency towards a traditional concept of citizenship and finally, the fourth group (q4) is for students who have chosen response options that are closer to a conception of citizenship more traditional.
Figure 1 shows the results for each course. It can be seen that a greater number of students of 2 ° ESO course opt for the options tend towards a more traditional human rights and citizenship (56.1%), while a larger number of students in 4 of It shows a greater tendency to choose the concepts related to human rights and cosmopolitan citizenship (59.9%).
Figure 1: Percentage distribution according to the concept of citizenship obtained for each educational level

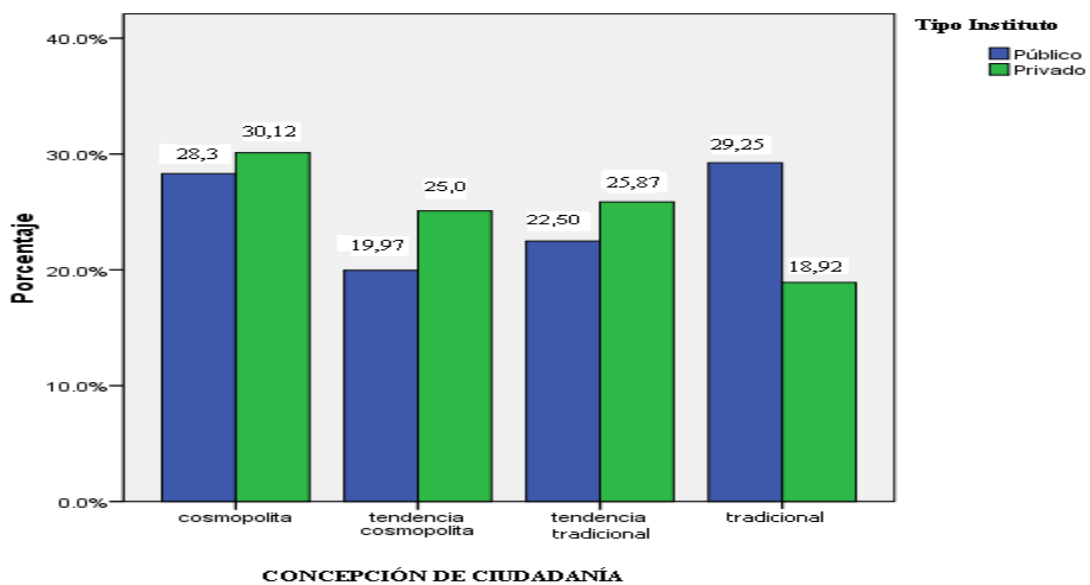
Figure 2 shows the results by type of school. It can be seen that there is to some extent an homogeneous distribution in the case of students attending public institutions, in this case showing a slight preference for the options that tend towards a more traditional conception of citizenship (51.74%), while a larger number of students in private schools show a greater tendency to a more cosmopolitan conception of citizenship (55.22%).


Figure 2: Percentage distribution according to the concept of citizenship obtained for each type of school

The exploratory analysis presented in the box plot (see Figure 3), suggests that there are differences between Spanish and foreign students in relation to their conceptions of citizenship, showing that Spanish students tend towards a more cosmopolitan approach while Foreigners students tend to a more traditional approach of citizenship.
Figure 3: Students' conceptions of citizenship with regard to their educational level, gender and region

At the same time, figure 3 shows the differences found between students from different regions with respect their conception of citizenship. In this case, students of the Autonomous Community of Madrid show a greater tendency towards a more cosmopolitan view of citizenship, while students of the Community of the Basque Country show the opposite trend towards a more traditional view of citizenship.

Another interesting data are the differences between men and women. As can be seen in the same Figure 3, women tend towards a more cosmopolitan approach of citizenship while in men shows the opposite trend, preferring to a more traditional approach.

These differences can be seen in the box plot (Figure 3), based on the median and the dispersion measures that are shown in the boxes. The black horizontal line corresponds to the median, which is inside each green or blue box. The lines emerging from each box inform us about the extremes values of minimum and maximum, in which each end of the box corresponds to the percentiles 25 and 75, respectively.

Furthermore, based on this information, we performed a multiple correspondence analysis, in order to analyze the possible relationships that might exist between the different Spanish autonomous communities, nationality, gender and educational level in regard to the different conceptions Citizenship (Figure 4).

As shown in Figure 4, the data reveal that the notions of citizenship that show a greater tendency towards a more traditional approach are associated with: the Community of the Basque Country, males and students from the 2nd grade of compulsory secondary education. These data can be seen in the upper circle of this figure. In contrast, the data show that the conception of citizenship that shows a greater tendency towards a more cosmopolitan vision is associated with: the Community of Madrid, females and students from the 4th grade of secondary compulsory education. These data can be seen in the lower circle of Figure 4.

Also in this same figure, it can be observed that these variables are more associated with the Spanish origin of the students than with their foreign origin, if we take into account that students of foreign origin are located in the opposite side of the figure.

Once detected the existence of relationships between demographic variables and different conceptions of citizenship, the respective statistical tests were performed in order to see if the differences shown between each of the categories of variables were statistically significant.

CONCLUSIONS

This work has allowed us to identify student´s conceptions of citizenship in compulsory secondary education. Our results reveal different trends shown by students toward a more traditional or more cosmopolitan conception of citizenship, depending on their level of education, type of school they were attending (public or private schools), and the autonomous region in which they were living. Overall, the data reveal that students of the 4th year of compulsory secondary education (16-17 years old) show a greater tendency towards a more cosmopolitan citizenship, when compared with students of 2th grade (14-15 years old).

On the one hand, these results are to some extent similar to those reported by Lister, Smith, Middleton and Cox (2003), where the dominant model of citizenship for young people when they were asked about how they perceive citizenship and how they see themselves as citizens, was related to a more relational model of citizenship. Along with this model, it is noteworthy that some young people gave importance to the participation on their own life experiences, in which an important element was focused on the constructive social participation within the various communities in which they participate, although this was not the dominant model. On the other hand, the data from this study also showed how young people frequently understand citizenship based on a number of models simultaneously, when they try to make sense of citizenship and their own identities as citizens. These facts illustrate that young people still are not able to handle a more definite conception of citizenship.

Also, the results obtained in this work are in line with those obtained by Osler and Starkey (2003), in their study with young people that were living in a multicultural community of Leicester in the UK. This study revealed how these young people tend to have a more cosmopolitan conception of citizenship, showing also multiple and dynamic identities in their lives.

In general, the results of this study indicate the existence of important relationships between different conceptions of citizenship and the variables: type of school, gender, educational level (age), region and country of origin.

Regarding gender differences, it is important to note that they are consistent with the results reported on research conducted in 28 countries by the IEA "Civic Study", in which women had not only a better understanding of Human Rights but also showed more support for minority groups (Torney-Purta, Wilkenfeld and Barber, 2008). Similar results were obtained in a study conducted with teacher training students from three different countries (Spain, England and Hungary), in which women showed more positive attitudes towards cultural diversity (Navarro et al, 2008). Also the study carried out by Haste and Hogan (2006) showed similar results in relation to the fact that women scored higher on issues related to helping the community and the environment.

Furthermore, the differences between the different conceptions of citizenship by educational level may be due to developmental differences in the cognitive and social development of the students (ranging from 14-15 years old to 16-17 years old), which may explain their different views on citizenship in the two educational levels studied.

Similarly, other factors may be influencing the development of different conceptions of citizenship by young people, such as the social, the family and the national context (Alviar-Martin, Usher, Randall and Engelhard, 2008), as well as the learning and experience that take place at the school. In this line, an important element that has to be taken into account is the influence of the curricular subject of Education for Citizenship, as well as the specific civic culture that has been implemented at each school with respects some important dimensions of citizenship. Therefore, it is important to look into these aspects in order to establish which variables are influencing the development and understanding of citizenship issues.

Abstract: The present work is part of a master's degree research that aims to analyze Rural Education experiences and education dynamics taking place amid processes of peasant territorialization. Therefore, we sought to identify advances, contradictions and challenges faced by Rural Education in Brazil nowadays. This work presents theoretical considerations on the concepts of Rural Education, Peasant Territory and Education Territory, which guide the construction of the problem investigated and support our analyses of the social representations constructed by the participants in different education experiences. Our preliminary and partial analyses reveal diversity of social representations of Territory, Rural Education and Education Territory, indicating the occurrence of territorialization processes in search of new forms of sustainable rural development, based on agroecology and respect to cultural and environmental diversity.

Keywords: Rural Education; Educational Territories; Peasant Territorialization.

RURAL EDUCATION AND PEASANT TERRITORIES

The expression *Rural Education* and its concept started to be constructed in 1990, but important references are found in Popular Education, which, for Paludo (2006), originates from popular social movements of Latin America (Movimentos Sociais Populares da América Latina). It was created and expanded as a set of educational theories and practices in opposition to those traditional and hegemonic. This type of education seeks empowerment, organization and prevalence of the working class, aiming at the construction of popular alternatives for education and development. Therefore, it becomes an instrument of struggle against oppression and exclusion, seeking to offer holistic and comprehensive education for people who have rights, historic memory and ability to understand reality critically. Similarly, Silva (2006) presents Popular Education as *"a set of practices that are performed and developed in a historic process in which the popular sectors are immersed"* and as *"strategies of struggle for the survival and freedom of these sectors"* (Silva, 2006, p. 70)

Rural Education presents the construction of an education Project that reinforces the importance of educational activities for humanization and critical integration of individuals into society (Caldart, 2004), from the perspective of peasants, conceiving the struggle for a rural concept of education, rural area and development that deals with different social groups and hegemonic development models. Rural Education, according to Caldart (2004), can only occur along with the transformation of dehumanizing social contexts, based on the rise of rural people as the subjects of these transformations. Therefore, education is conceived as a work done by country people, "Rural Education as intentional cultural resistance targeting cultural changes and more comprehensive humanization" (Caldart, 2004, p. 155). It means, therefore, that education is made *by* and not *for* country people. It belongs to them and, at the same time, seeks to make them organized, engaged and involved, participating in the decisions about their own destiny.

Rural Education involves different subjects that live and work in the country area and constantly face processes related to territorialization, deterritorialization and reterritorialization. The movements of communities affected by dams, for example, reveal the struggle of subjects constantly deprived of their territories because of the construction of hydroelectric plants that flood large inhabited areas and change the flow and volume of waters throughout the course of rivers. These dams, many times related to interests of private companies and the hegemonic energy model, demonstrate the selection of a development model that provides territory to capital, transforms resources into money, life into goods and takes territories from people of the country, allocating communities in different sites as though their territorial needs could be supplied by material things, such as soil, a house or a street.

Monoculture and biotechnology are also examples of loss of territory in the country, through the increasing use of transgenic seeds. The pressure made by large companies that deal with monoculture, including eucalyptus in the northern Espírito Santo and sugarcane in the Triângulo Mineiro, induces many family

farmers and peasants to sell or rent their lands and move to cities, and they hardly ever manage to return. Besides, transgenic seeds make farmers depend on the companies that produce them, hindering the autonomy of farmers over their lands. In some cases, transgenic plants contaminate Creole plants in other properties, which occurs to maize, whose pollen is spread by air.

The movements of landless rural workers are another example, when they occupy unproductive lands or lands where workers had been illegally exploited, when they recover areas that had been a symbol of inequalities, in which the organization of the agrarian sector expels people and confiscates their lands, giving a new meaning to that site, providing a new territory to peasants and, many times, grouping subjects of different origins, from different locations, with different territorial concepts, that will affect the forms of organization of these new territories...

The Conquista Conjunta de Terras (Joint Conquest of Lands), in Araponga-MG (Campos, 2001), is also a movement focused on territories that enables landless family farmers, sharecrops and tenants to acquire properties, also constructing a network of communitarian and social relations among farmers and strengthening their organizations.

Rural Education is strongly rooted in rural social struggles that demand access to land and decent permanence in the country site, also understood as educational processes. While emerging as a consequence of many of these claims and mobilizations, Rural Education is also an instrument of this struggle for the construction of new political projects for the development of rural areas. In this sense, according to Arroyo (2004), education for rural areas cannot be treated isolately, but it must be inserted in broader discussions about the present rural context. For Caldart (2008), it should also consider the logics of life in the country and its multiple dimensions. Therefore, it must be related to the perception that the space it occupies and recreates is its territory. Thus, there is no way to separate Rural Education dynamics from the territorial processes experienced by the rural population.

The expression "of the country" in Rural Education is related to the identities and historical processes experienced by social groups in rural environments. The subjects of Rural Education and of the country are the same (Caldart, 2004), those who live and remain in rural areas: peasants that struggle for land reform and better living and working conditions in the country, farmers that defy an exclusionary model of agriculture, former slaves and Indians who seek to enforce their rights and identities, riparians, landless people affected by dams; country people and people from the waters and forests, etc.

Although Rural Education has multiple subjects, coming from several contexts, it is possible to say that they form social groups of peasants, because they resist and continue living in the country, occupying spaces, constructing, creating alternatives for production, income generation and education, deconstructing and reconstructing territories, searching for alternatives different from those historically imposed to rural populations by hegemonic country models. Rural Education, as a process of knowledge construction and as a movement of peasant resistance, is also a process of identity construction, peasant identity affirmation, with its characteristics, living spaces and territories (Fernandes, 2008, p. 63).

The concept of territory has been discussed in many fields of knowledge, mainly in studies on societies and their geographic spaces. Territory is many times understood as a limited and controlled space upon which certain power is exerted, many times the power of a state; as a product of appropriation and symbolic valuing by a certain social group; as a space for economic relations; and as a space for the expression of the relations between society and nature, of certain forms of interaction, use and appropriation of natural resources. These are some forms of understanding that reveal some aspects of territories: their political, cultural, economic and natural dimensions (Haesbaert, 2003, p.13).

For Haesbaert (2007), the approaches that prioritize the political dimension of territories and those that favor its natural dimension constructed the two most traditional thinking in the geographical definition of this concept. The cultural dimension of territories have also deeply affected theoretical debates based on the reframing of local dimension, identities and specificities that draw the attention to the existence and re-existence of different social groups. Although seeming to be different trends of analysis of territories and being used this way many times, these dimensions are complementary for understanding space dynamics, forms of organization of social groups, symbolic and power relations, relation with nature, the State and the interests inside and outside territories.

Territories, as a social construction, follow the dynamics of the groups that created them and are always moving, through constant processes of construction, deconstruction, creation of a new meaning or reconstruction, or processes of territorialization, deterritorialization and reterritorialization, which occur at different time intervals, either some hours or over generations, determining continuous or discontinuous spaces, whose limits are well defined or more fluid, with overlapping boundaries and territories that coexist in the same space...

Contemporary authors, including Rogério Haesbaert and Marcelo Lopes de Souza, consider territories as a force field holding different spatial and temporal scales, spatially limited by the social relations of power in their multiple dimensions: political, economic and symbolic. Thus, they emphasize the relational character of territories, instead of considering them as a physical substrate or a material basis that preceded societies.

Territories, "are essentially a defined space limited by and from relations of power" (Souza, 1995, p.78). They should not, however, be confused or reduced to the image of the State, to which the concept of national territory is connected, nor to the recent ideas about Rural Territories and Territories of Citizenship, in the scope of public policies and rural development, which will be later discussed. A territory can be understood as the projection of social relations in space, the result from the articulations among local social actors that recognize a common identity, creating a web of forces and social and power relations, leading to the definition of a limit based on otherness (Flores, 2003; Souza, 1995).

Territory is also defined as a "space simultaneously dominated and appropriated" (Haesbaert, 2002, p. 121), where there are forms of control by a certain group or class, in which bonds of social identity are created. Domination and appropriation constantly occur in an unequal relationship of forces. In the same vein, Fernandes (2004, 2008) declares that territories, regardless of their form and content, are always a political construction based on relations of power. Territories are a convention and confrontation: "Exactly because Territories have limits and boundaries, they are a conflicting space" (Fernandes, 2004, p.4).

Therefore, territories are understood as places of connections, nets and social, political and symbolic articulations among groups and subjects in a geographical space, which delimit a social space while creating movements among local, regional and global scales. Social nets involve the internal and external flows of territories. The flow of ideas, practices and existence generates the following movements *i)* territorializing, which establish new territories, connecting actions and social groups, defining new limits, boundaries, territories; *ii)* deterritorializing, which disrupt political, economic and cultural frontiers, and at the same time, *iii)* reterritorializing, which interconnect different spaces, subjects, ideas and actions (Haesbaert, 2002).

TERRITORY AND EDUCATION IN THE SCIENTIFIC FIELD

In the field of educational research, the concept of territory has been observed more often in studies and scientific works on Rural Education, maybe because this is a field of interdisciplinary research (Ferrari et al, 2009), gathering interests of different areas of knowledge, including Education, Geography and Sociology; focusing on the geographical area, on a certain social group and its territories, supporting Rural Education and not only education in the country, thus discussing the issues related to the development of the rural space, namely, land reform, forms of organization and the strategies of social reproduction of family farming and peasants; through articulation with rural and urban social movements; dialogue with public policies for education and rural space, which, since the last decade, have been adopting, as we will see later, the perspective of " territorial development", a concept permanently discussed in the current scenario.

Over the past two decades, authors and researchers on Rural Education have discussed the concept of Territory, including Fernandes (2004; 2005; 2008), who perceives territories as a multidimensional category fundamental for research on Rural Education, conveying the understanding of rural areas as a peasant territory, thus bringing into discussion the issue of the development intended for the rural space. The idea of territory can be identified between the lines in the approaches of Miguel Arroyo (2004) and Roseli Caldart (2004; 2008), although this concept is not always used directly. It is observed in a concept that has been discussed for a long time in Rural Education by researchers and rural social movements: the expression *of the country*, instead of *in the country*.

Although being used for some authors, territory is a concept under construction in Rural Education. The data of the exploratory study, in which we analyzed the academic work of Rural Education researchers on territory (Ferrari et al, 2009), reveal that the concept is not focused on research works and is employed based on many theoretical references, which may indicate, on one hand, an incipient appropriation and the need for greater depth about the concept of territory, and, on the other hand, the diversity of approaches and expansion of the theme "Rural Education and territory" nowadays. In the same vein, a continuous exploration of this issue is necessary due to its theoretical relevance, the existence of some gaps in this field of knowledge and the daily challenge faced by Rural Education to construct an educational rationale centered on the collective subject and not only on schools, also considering the importance of the territory to which it belongs, of the social context in which it dwells and the movement that supports its affirmation as subject. Therefore, a study on territories and Rural Education has much to contribute.

TERRITORY AND EDUCATION IN THE FIELD OF PUBLIC POLICIES

The concept of territory is also conquering space in the field of public policies. In 2003, a rural development program focused on territory carried out by the Secretary of Territorial Development (SDT) and Ministry of Agricultural Development (MDA) was implanted in Brazil. Ever since, 164 Rural Territories were created in different states and regions of the country (Brasil, 2010).

The implementation of these territories creates new arrangements among cities and between government and society for the management of public resources. This territorial focus, namely, the approach that deals with the scope and concept of territory in the rural development is explained in the official discourse (Brasil/MDA/SDT, 2005) by the need for relating rural space not only to the agricultural sector; because of its local action scope, although more comprehensive than a municipality; its compliance with the current movement for political decentralization, adopting ideas such as the participation of different social actors, the strengthening of social nets and the relation between public and private enterprises, social and productive policies, internal and external instruments, targeted at "sustainable development".

Since 2008, with the creation of a program called Territories of Citizenship Program (Programa Territoriesda Cidadania), some rural Territories were reorganized and started to be considered as territories of citizenship, including different actions in three axes connected to 22 Brazilian ministries: productive activities; infra-structure; and citizenship and rights. Today, there are 164 Territories, 120 of which are Territories of Citizenship (Brasil, 2010).

Rural Territories were created not only in Brazil. Nowadays, there are many processes that arise from or as part of globalization, highlighting more localized ranges. Several authors have focused on local phenomena and dynamics, using different concepts and approaches: "relocalization" (Canário, 2005), "reterritorialization" (Haesbaert, 2002), "recontextualization" (Giddens apud Canário, 2005), or even "reimplantation of the social bond at territory level" (Rifkin apud Canário, 2005).

In the context of the creation of Education Territories of Priority Intervention (TerritoriesEducativos de Intervenção Prioritária - TEIP) in Portugal, Canário (2005) analyses the relocalization of schools, mainly rural schools, related to a rationale of local development. This author reveals two different theoretical ideas about relocalization and makes us curious about the difference between the construction of School Territories and Education Territories. For this author, the TEIP convey an idea of territory connected to the construction of school nets seeking rationalization and efficiency in school management. The concept of Education Territories, on the other hand, emphasizes education activity in a dimension beyond school space, pointing out the spatiality of education, in which the education space is the social space. The understanding of the education activities amid a territorial context is a key aspect, according to Canário (2005), for the construction of meanings, something essential for learning, and helping education in the creation of emancipatory dynamics that change social contexts, placing education in the center of a political and philosophical debate, relating education project to political project.

TERRITORIES AND RURAL EDUCATION: A RESEARCH PROBLEM

The concept of Education Territories used by Canário (2005) seems to be close to the concepts and principles of the Rural Education in Brazil, mainly in relation to the principle of Rural Education for the construction of a political project for the development *of the* country. However, this concept does not involve satisfactorily the territorialization processes deeply influenced by education. The concept of Education Territory seeks to contribute to education by the territorial rationale, and education does not separate education from politics and territories. Rural Education, beyond the construction of this Education Territory, also aims to contribute for the consolidation of the peasant territory, materialized as a space for life, work, struggles and education. Therefore, together with the concept of Education Territories, we can think about Rural Education dynamics – or country education dynamics – which take place in peasant territories, as an alternative to materialize a territory in space, consolidating rural territorialization.

In a research carried out on a Rural Education experience in the Serras do Brigadeiro, in the Escola Família Agrícola Puris (EFA Puris), Zanelli (2009) deals with the construction of territorialities based on actions of family farmers in the municipality of Araponga-MG, such as the Joint Conquer of Lands (Conquista Conjunta de Terras) and the transition of a conventional agricultural model into agroecology, which is understood as a different approach for thinking and practicing agriculture, relating popular, traditional and scientific knowledge with practices appropriate for each context, based on social and environmental sustainability, solidarity, empowerment of farmers, food diversity and sovereignty and the construction of autonomy, which leads to technical and political transformation of conventional agriculture. The territorialization process of the agroecological knowledge, which can also be considered, ultimately, a form

of country territorialization, according to Zanelli (2009), is carried out with the consolidation of the EFA Puris, in a long trajectory seeking to strengthen family farmers in the region.

> More than a school targeted at Rural Education, [the EFA-Puris] it encompasses the broadening of the territory of family farming in the region (Zanelli, 2009, p. 64).

According to the author, the EFA leads to considerations about the local context, seeking to empower organizations and create mechanisms to make young students overcome difficulties and construct new forms of thinking and living in the rural space, in other words,

> a school located in an area of conquest of land is more than an object in the space; but [...] the materialization of territorialities historically desired and constructed through organization, a collective work of freedom seekers, addressing farmer social reproduction (Zanelli, 2009, p. 66).

In another research work on resistance, the resilience of indigenous Puri in the Serras do Brigadeiro, Barbosa (2005), highlights the invisibility and silence of rural workers of Araponga-MG, resulting from a long historical process of cultural standardization and colonial domination; and it corroborates the signs of the emergence of territorialities of the country, of construction of other possible contexts by means of agrology and ecopedagogy, affirming that:

> Secular invisibility and silence, which shadow and limit the absence of certain people, in that specific territory, cannot hide social memory and reality, which keep on resisting cultural uniformity imposed by the colonial historical domination. Today, this patient, persistent and resilient colonial trait demands space to construct another possible reality, unheard-viable (...) territories update and manage the popular poetic hearing that creates concepts through the complex local elaboration of agroecology and ecopedagogy. (Barbosa, 2005. P. 28)

The Rural Territory of Serra do Brigadeiro (TRSB) was the focus of a previous study (Ferrari, 2008), in which we observed the existence of multiple territorialities that do not comply with the rationale of construction, space and limit that created the territory, in the scope of politics and rural development. In other words, there are different territories socially constructed in areas within the formally implemented Rural Territory, which are reduced to the limits of the territory implemented, of the space defined by public policies, articulating conflict, overlapping or defining their boundaries very well, demonstrating more diversified and complex territorialities. The data of the research revealed the existence of social nets created by kinship and neighborhood, labor relations, articulations of the movements, social and union organizations, flows according to the need of access to services and markets, among others.

This research also revealed the existence of concepts of territory expressed by people directly involved in the management of the Rural Territory, which were somewhat shared by their social groups. However, among the concepts of territory, how have education and rural territories been appropriated, understood and reelaborated, namely, socially represented by the subjects involved in experiences of Rural Education in the Territory of the Serra do Brigadeiro? What do these representations reveal about concepts, practice and challenges in Rural Education? What do they reveal about the processes of peasant territorialization?

Whiled analyzing studies carried out in the Serras do Brigadeiro on the emergence of territories of family farmers (Barbosa, 2005; Ferrari, 2008; Zanelli, 2009) and noticing their relation with Rural Education, we questioned: how do rural educational dynamics take place in peasant territories? What do educational dynamics in the processes of peasant territorialization in the Serras do Brigadeiro indicate about concept, advances, contradictions and challenges in Rural Education?

The present research, therefore, aims to map and select some experiences of Rural Education present in the Rural Territory of the Serra do Brigadeiro; characterize them and their political articulations, historical aspects, principles and education practices; and identify the social representations of "Territory", "Rural Education" and "Education Territories" provided by the subjects involved in these experiences to identify advances, contradictions and present challenges in Rural Education throughout the processes of peasant territorialization.

Understanding that experiences of Rural Education are experiences of both formal and informal education, which occurred in peasant movements and social organizations aiming at the construction of a popular, autonomous and sustainable project of rural development, we can observe that there are many different experiences in TRSB, which, at first, we could consider Rural Education.

Considering these aspects, we decided to select qualitatively formal and informal educational experiences, prioritizing those whose information was of better quality. Thus, the present study focused on the experience of the Escola Família Agrícola Puris, a school in the municipality of Araponga-MG and on the experience of the Ecojovem, in the municipality of Divino-MG.

The Escola Família Agrícola Puris (EFA Puris) was founded in March 3rd, 2002, resulting from the farmer movements derived from ecclesial communities (Comunidades Eclesiais de Base - CEBs), the creation of the rural worker unions (Sindicatos de Trabalhadores Rurais - STRs) and a partnership with a center of alternative technologies (Centro de Tecnologias Alternativas da Zona da Mata - CTA-ZM), aiming at the construction of other forms of living and working in the country, reflecting about the need for an educational model appropriate for the rural context, concerned with providing comprehensive training for (a) young farmers (a) linked to projects of community development (EFA PURIS, 2008). In 2010, when it completed two years of operation, the EFA Puris had three classes of three series of high school, totaling 45 students in the technical program integrated to high school, which offered qualification in Agriculture and cattle raising, with emphasis on agroecology.

The Ecojovem is a group that offers training for young family farmers of the municipality of Divino. The itinerant training is provided in the rural communities of the municipality, aiming to awaken young leaders to struggle in their communities for changes in life and working conditions in rural and urban areas; recover rural cultural identity; exchange knowledge; train youth in agroecology; understand better the social relations of gender; and fight for the permanence of rural workers in rural areas. The Ecojovem was created in August 2009 by some young people involved with family farming movements, such as the STR of Divino, in areas of the TRSB and CTA, who observed the need for aggregating more young people in the political discussion of worker's union. Besides, the religious movement Pastoral da Juventude Rural was not working any more and elementary schools run by the union were not able to involve the rural young people of the municipality. These two experiences were relevant in the history of the municipality for young people training and union movements. Nowadays, the 43 young farmers participate in the Ecojovem, under the support and partnership of the STR of Divino, ECOSOL (a solidarity credit union), CTA-ZM, farmer association of Divino and the families and rural communities that host the young people that come for the meetings.

RURAL EDUCATION, TERRITORY AND EDUCATION TERRITORIES - SOCIAL REPRESENTATIONS UNDER CONSTRUCTION

Our research aimed to understand, based on the Moscovici Theory (2003), the social representations of subjects involved with the EFA Puris and the Ecojovem related to Territory, Rural Education and Education Territories, to unveil the meanings and practice involved in the territorial educational dynamics. For such, we interviewed four participants of the Ecojovem and 7 participants of the EFA Puris, to ensure the diversity of gender, age and forms of involvement of the different groups and subjects that participated.

Concerning Rural Education, the new meanings given to rural space, the focus on the social relations constructed in the countryside and the values of respect to nature are striking characteristics of the social representations mentioned by the interviewees. In the EFA Puris, although the educational dimension of social relations is present in the reports, the participants stressed the formal dimension of education, using in their speech about Rural Education expressions such as "school", "study", "student" and "teacher". It differs from the representations of the participants of the Ecojovem, who focused on education that takes place in daily life, collective experiences or the experiences lived with family, community and social organizations. In their definition of Rural Education, their representations are supported by actions such as "knowing", "understanding", "acknowledging", "learning", "seeing", "living together", "exchanging experiences" and "exchanging learning", which take place in the daily life, at home, at work, in conversation with neighbors, in activities, meetings.

This rationale makes sense when the context where the experiences take place is considered: in the EFA Puris, the representations of Rural Education are anchored in the formal education experience of the interviewees – school education, while in the Ecojovem, the representations are supported by an informal education experience, combining informal educational processes, valuing communication, creativity, expression and dialogue among people of different generations, origins and training.

The aspects highlighted in the representations of both groups are fundamental dimensions of Rural Education and help us to look at the different angles of an educational project, to understand its challenge and the complexity of the construction of another rural paradigm, mainly for rural youth.

Concerning territories, the social representations of the people interviewed focus different issues, which are not exclusionary, though. Therefore, these representations reveal visions of a territory as an occupied space, either spatially or symbolically limited, socially constructed, resulting from a relation between people and

between people and the environment; a space occupied by a certain social group, marked by identities and certain forms of interaction that allow their constant reconstruction.

The social dimension of territories stands out among these aspects, as well as the dimension of nature, the physical environment represented by forests, rivers, climate and biodiversity. What could be seen as a contradiction, in this case, shows us how the relation established between society and nature is related to a certain rationale and spatial organization. Thus, territories can be understood not only as a social construction, but a construction of certain space and context.

On the other hand, the idea of territory associated to nature stresses the context of these subjects, in a region where two parks were created: the Parque Estadual da Serra do Brigadeiro, founded less than two decades ago, and the Rural Territory of the Serra do Brigadeiro, less than a decade ago, which used the park, or the social articulation derived from it, as an identity axis for the agglutination of the municipalities (Ferrari, 2008). These two ideas, therefore, are very close to the daily routine of these subjects and anchor their representations.

On one hand, this connection of different representations challenges our understanding about the meanings ascribed to territories. On the other hand, the mixture of ideas indicates the representations constructed in the experiences lived, the reflections related to ecological agriculture and the relationship with an environmental preservation area. This is a common aspect to the representations of territories, present in both experiences analyzed, although the EFA emphasized territories, while the Ecojovem focused on the idea of park.

CONCLUSIONS

Brazilian rural spaces have passed through significant changes in the last decades, which contributed for the construction of other concepts about rural areas and their dynamics. For Wanderley (2000), these transformations result from economic globalization; the increasingly significant presence of international influence on policy and economy regulation; employment crisis, the post-fordist relation changes and the transformations of working regulation alternatives; economic decentralization, which favors the implementation of industries and commercial centers in certain rural areas; increased forms of access to goods and "modern" services previously restricted to urban areas, changing the life conditions of inhabitants of rural areas; and the demographic growth together with the adoption of new economic and social policies, leading to reduced migration flow from the country to cities, in certain cases, and attracting other social categories for the rural environment.

Carneiro (1998) and Ferreira (2002) added that it means a demographic revitalization, following some tendencies of growth of rural population, in opposition to the prediction of extinction and future and unavoidable urbanization and expansion of the rural-urban *continuum*. This revitalization brings economic and cultural diversification due to the incorporation, or acknowledgement of the performance of non-agricultural activities by farmers or peasants, a phenomenon Schneider (2003) highlighted and called *pluriactivity*, due to the migration from urban population sectors to the countryside, in search of leisure or "alternative" life styles. Besides these changes, there are other ideas about the relation between society and nature, environmental preservation actions and search for sustainability, placing rural space at the core of conflicts and struggles related to the environment, models of agricultural production and the new socio-spatial dynamics resulting from social movements.

These visions of rural space despise its historical concept based on oppositions, such as rural-urban, countryside-city, agriculture-industry, traditional-modern, uncivilized-civilized, non-technical-technical, resistant to changes-dynamic/flexibe; a space to be transformed by civilization processes, modernization and technical procedures, which must be adapted to market logic, in a context of globalization and hegemony of neoliberal policies (Moreira, 2007).

Therefore, there is a break with the concept of rural space as a lower locus, inferior and marginalized, compared to cities. There is new understanding about its inter-relations with the urban space and the new subjects and dynamics that now characterize rural space. These subjects are former slaves, Indians, peasants, settlers, family farmers, sharecroppers, and many others. They experience different non-agricultural situations in the rural space, including many economic, political and cultural relations.

This process, in which new meanings for the rural space are constructed/deconstructed, has been affected by the reframing of the natural world and nature. Its roots are the ecological and environmental movements, considered counter-hegemonic, "globalization from below", and resistance to "localized globalism" and "globalized localism" (Santos, 2002).

The ecological and environmental movements in Brazil began to question the conservative technological modernization model, the package "Green Revolution", which leads to the poisoning of soils, waters, food and farmers, loss of biodiversity, siltation of rivers, poverty, unemployment, exploitation of rural workers,

exodus to the cities and concentration of land (Moreira, 2007). In this context, counter-hegemonic movements emerge to vindicate land reform, new labor relations and care with nature, the use of agroecology and alternative therapies for people, animals and plants.

The reframed rural area is now understood based on its economic, political, cultural and environmental dynamics; as a space not only for agricultural production, full of histories, cultures, complex social relations, different social nets, new institutions and fields of disputes and conflicts at many levels.

This is the field of Rural Education, with a challenge more complex than just thinking about the inclusion of students from the rural area or the contents related to agriculture: it implies the need for considering what rural population think about their territory and how education can strengthen it

The social representations of the EFA Puris and Ecojovem reveal the construction of new visions and more sustainable practices related to rural space, including rural agroecology, respect to cultural and environmental differences and, finally, re-territorialization of peasants in a hegemonic context that tries to impose forms of development that tend to de-territorialize nature, popular knowledge, and subjects with their stories and cultures

318 - Problem Setting and Reflections on One Teacher-Researcher's Educational Practice: May the Students Be Subjects of the Relationship with Knowledge in Physical Education Classes?

Luciana Venâncio[1] & Mauro Betti[2]

[1]luciana_venancio@yahoo.com.br, [2]mbetti@fc.unesp.br
Faculdade de Ciências e Tecnologia, UNESP – Univ Estadual Paulista, Presidente Prudente, São Paulo, Brasil

Abstract: The established relationships within the school among teachers, students, teaching, learning, and knowledge production have been a recurring theme in the contemporary world's Education field of study. Searching new perspectives toward these issues has been the focus for researchers in Latin America, North America, and Europe. Possible advances from the epistemological standpoint would require considerations on the actual and concrete contexts of knowledge elaboration *with* and *within* the school. Historically, the students' relationship with knowledge has not been considered in Physical Education (PE). Students as subjects of learning have been relegated to the background, because of some theoretical and methodological propositions in the area that consider the movement more important than the movement's subject. We can infer that such propositions were not able to think properly about the movement's subject and his/her singularities. Despite the consensus on which contents should be taught in PE, it is necessary to raise some questions that remain unanswered with consistent arguments referred to knowledge: What to teach and learn? What is the significant knowledge? How to teach and learn? How to motivate and mobilize knowledge? What to teach and learn for? What to motivate and mobilize knowledge for? What is knowledge in PE? What is the meaning for the student in studying (learning) PE at school? What is the meaning of PE? This Doctoral project is based on qualitative, descriptive, and interpretive analysis by one Brazilian female teacher-researcher who works in a public school in the city of São Paulo. It seeks to reveal how students' build and manifest their relationships with the knowledge, and what is the knowledge needed to an educational practice with the perspective to appropriate, change and pronounce the world by such subjects. The overall goal is to understand how students attribute meaning and make sense of relationships with knowledge developed *with* and *within* PE classes. Beyond the aspects of such shared educational intervention, the theoretical referential of Elenor Kunz's critical-emancipatory proposition, Bernard Charlot's ideas about the notion of relationships with knowledge, and Paulo Freire's assumptions on pedagogy will subsidy this investigation. The methodological procedures will use the technique of focus groups, interviews with students as subjects, record analysis of photographic images, videos, testimonials, and descriptive analysis of situations experienced in PE classes. The preliminary indications of this study point out the need to clarify principles that leads to an educational practice in PE concerned with subjects who learn and teach each other, and with the notion of relationship with knowledge. These principles can be tied to the critical and reflective reasoning by the teacher-researcher who questioned the very logic of the teacher education and the logic of her teaching practice, characterizing an educational practice shared with the subjects, i.e., focused on students in their relationship with the knowledge shared in PE classes.

Keywords: Teaching; Learning; Knowledge; Physical Education.

THE CONTEXT OF RESEARCH

The relationships within the school between students, teaching, teaching practice, training and knowledge production have been a recurring subject in the field of study and reflection of Education in the contemporary world. Discuss and propose concrete changes related to these themes have been the focus of research in Latin America, North America and Europe in order to achieve progress in epistemological and empirical propositions that characterize Education.

In the specific case of this investigation, the framework will be build up from the processes of elaboration and comprehension of knowledge in Physical Education (PE) constituted in the relations between subjects "students" and "teacher", revealing the shortcomings of some theoretical and methodological propositions in which the relations with knowledge and subjects were not intentionally considered. In this direction, we consider Charlot's (2000, 2005) and Freire's (2002) contributions. The convergence of these two authors may be justified by the fact that they attribute fundamental importance to the issue of the *senses* on the

appropriation of knowledge, the willingness to take into account the collective and political dimension of education, and at the same time, not to reduce the subjects to their social group.

There is a set of actions taken by students and teachers at school, which is characterized as producing knowledge of different natures. Libâneo (2002) raises some suspicions about these practices of knowledge production, and also clues for investigation about what has been the role of schools and teachers in knowledge elaboration and its relations with the profession. His suspicions provide a diagnostic of Brazilian school situation, based on research and observations of reality that address interdependent issues such as: the quality of teaching, the weakness of learning (lack of school goals), low quality of professional performance (ethical and technical competences), distance from the growth of academic investigation and research on teachers, teachers' educators and scholars who do not know concrete problems of everyday school life (impoverishment and fragmentation of knowledge), the emphasis in the theory of teacher education (working conditions, precarious professional preparation, policy and organization of educational systems, conflicts and contradictions of teaching duties, and disregard about curricular principles), theoretical divergences of sectors in the educational field (conflict among traditional, modern, postmodern, and post-critical conceptions) and reduction of investigative interest in issues directly related to the student (quality and significance of learning).

Moreover, Libâneo (2002) also places his bets that refer to education as a right, and therefore the production of scholar knowledge, as he conceives it, is linked to the need for: reopening the debate and taking position toward the formative objectives of the school, consistent theoretical and practical preparation with good quality for teachers, build critical subjects (cult teachers), provide students with concrete scholar contents (systematized knowledge) to intervene critically in their own reality, turn the focus on the contents of teacher education to the living experiences at school, introduce in teacher education the development of competences related to thinking (new vision of teaching and learning), to reassess the profile of teachers' educators in initial and permanent education, to integrate strategies and evaluation procedures consistent with the work developed in schools and propose effective changes in teachers' salary and working conditions.

Affected by these clues and bets for research, our magnifying glass will be specifically placed on the notion of relationship with knowledge between teacher and students, and how such a relationship is established and appropriated by the subjects, assuming that learning means an appropriation of knowing to be *within* and *with* the world, and it is a singular characteristic of the human subject.

We are submitted to the fact of having to learn "many things" to appropriate the world. In the view of Charlot (2000) the term "learning" is very comprehensive, so part of the question consists in: What is learning? What is knowledge? Learning can be, for Charlot (2000, p.59), "to acquire a knowledge in the strict sense of the word, i.e., an intellectual content ("put things in the head", as the youngsters say), then, it means learning grammar, mathematics, [...], the circulation of blood, history of art." But learning can also mean mastering a subject or an activity (tying shoelaces, swimming, reading, etc.) or entering into relational forms (greeting someone or seduce):

Learning is to exert an activity in situation: in one place, at one time in his/her history and in diverse temporal conditions, with the help of people who help them learn. The relationship with knowledge is a relation with the world, in a general sense, but is also related to these particular worlds (media, spaces...) in which the child lives and learns. [...] The places where children learn have a different status from the standpoint of learning. The family is a living space [...] and affective group in which one main function is to educate. [...] The central function of school is to instruct, but it participates in education and is also a living space (Charlot, 2000, p.67).

The family, school, church, neighborhood are places and living spaces, where children and youngsters learn in contact with people with whom they maintain relationships, which assume different characteristics. Thus we believe that a teacher instructs and educates, he/she is an agent of an institution, represents a discipline, and has peculiarities. The relationship that a student has with a teacher can be predetermined: they are relations with his/her knowledge, professionalism, institutional status, with his/her person. Both student and teacher may assign other meanings to their relationship that is defined, in principle, as a relation of knowledge.

The relationship with knowledge is not only marked by the place and people, but for a moment too. Learning, under any figure whatever, is to learn in a moment of one's own history, but also at a time of different and unique histories: from the humanity, the society in which I live, the space in which I learn, the people who are responsible for teaching me. The pedagogical relationship is a moment, i.e., a set of perceptions, representations, and current projects inscribed in one's appropriation of his/her individual past and projections – that each one builds toward – the future (Charlot, 2000).

Freire (1983) points out that the characteristics of a human being, a being of relationships, is the ability to reflect about him/herself, about his/her own reality. Such a reality must be the object of one's own thinking

and knowledge put into action. This makes one be able to relate to others, leaving and projecting him/herself on others, to transcend and differentiate distinct existential orbits than him/herself.

Therefore we believe, in consonance with Pérez-Gomez (1998), that the investigative process of Education, regarding the knowledge elaboration, has a subjective and complex character and requires research methods that respect the nature of educational phenomena (social phenomena).

However, the characteristics of the social phenomena, in general, and educational phenomena are different from natural phenomena observable and measurable, particularly as they are presented as unfinished, have a creative dimension, self-formative, intentional, and are polysemic, i.e., have many meanings.

Thus, the investigative procedures of constituent knowledge of everyday school life, whether to understand and transform teaching, should question the production and exchange of meanings in complex school life (Pérez-Gomez, 1998), which present some universal assumptions in the form of teaching designs.

Toward these universal assumptions, we highlight two issues raised by Charlot (2005). The first relates to the concept of mobilization needed to relations with knowledge: "Nobody can learn [...], without a personal mobilizing, without making use of one's self. Learning is possible only if one is imbued with the desire [...] and if there was involvement of who learns (p.76). "Another universal of the education appointed by the author refers to the fact that the teacher should be responsible for motivating students to mobilize their knowledge, not to feel a victim of the students' lack of mobilization.

Freire (2002, p.46) stressed the importance of valuing the student as a being of relationships and argued that teaching requires the recognition and assumption of the cultural identity:

One of the most important tasks of the educative-critical practice is to provide the conditions under which students in their relations with each other, and all with the teacher rehearse a profound experience to take up themselves. Coming out as a social and historical being, as a thinking being, communicative, transformer, creator, maker of dreams, able to be angry because able to love. Coming out as a subject because he/she can recognize him/herself as an object. The assumption of ourselves does not mean the exclusion of others. It is the "otherness" of "not me," or "you", which makes me assume the radicalism of myself.

It is in this context that research on the practice are announcing new paths for understanding the educational practices and knowledge originated from them (Pimenta & Franco, 2008a; Pimenta & Franco, 2008b; Roldão, 2010; Trindade & Cosme, 2010). The issues involving relations with the knowledge that shape the teaching profession in contemporary society, at the same time that set problems on the characteristics of teacher education, put the challenge to include investigations that consider the students in this discussion.

We emphasize, however, that this view, which stresses the teacher's educational action must be analyzed under criteria, given that previous knowledge and experiences of students in performing a particular school activity, may reframe the relationship with knowledge in the daily classes.

THE RESEARCH PROBLEM

Knowledge, for Charlot (2000), as well as information, is under the primacy of objectivity, but it is information that the subject appropriates, and in this case it is also knowledge. Because knowledge produced by the subject will be confronted with other knowledge produced by other subjects, that could, in principle, initiate from the order of the object and reach a reportable product, i.e., a kind of knowledge, which consists of information and knowledge.

Thus, the intent and direction of all educational research is the transformation and improvement of practice. This practice is justified by ethical and political principles, not simply technical. In the practice of classes' environments, the selection of contents, the definition of methods, modes of organizing space, time, and students as well as the decision on the criteria and assessment instruments are, in essence, ethical and political decisions. As a result, it is necessary to rethink the didactics beyond the technical rationality, because of the characteristics of teachers' work. The focus should be on the mobilization of knowledge deemed most relevant in the educational process in order to raise the comprehension of teaching as a concrete reality.

The reductionism, particularly sociological and psychological, are old in an attempt to diagnose and prescribe the directions of Education, ignore the polysemies of educational practices and subjects' intentions because they are at once social, psychological, cultural, economic, biological, etc. (Libâneo, 2002). The more we recognize that educational practice is not reduced only to school practice, the more necessary is to understand that the relationships among individuals and social, physical, ecological, cultural, economic, political, aesthetic and technological demands require a field of integration for consistent theoretical and practical interventions, that focus their intentions on the subjects and the relationships they establish with their lives.

Teaching, as a practical activity, is mediated by exchanges of educational influences exerted in guiding students. Understanding life in the class environments is an important aspect to minimize arbitrariness in the

intervention. This is because we are dealing with subjectivity, interactions between individuals, inserted into unfinished and complex realities. According to Pérez-Gómez (1998), while no one intervenes and experience, it is not possible to know, understand and interpret the characteristics and peculiarities of his/her being.

Therefore, it is necessary to create and incorporate critical and rigorous educational work, when we think of teaching and research on teaching, for various reasons, among which we mention the teachers' and students' life history, continuing education, teachers' characteristics, sociocultural and economic conditions that are relevant aspects for the incorporation and modification of the *habitus* of being a teacher (Sanches Neto et al., 2006). By the way, *habitus* is a system of dispositions; ways of perception, feeling, doing, and thinking, that take us to the action in a certain form in a given circumstance (Bordieu, 2001).

Bourdieu (1994) rejects the objectivist reduction that denies the practice of agents, and he only concerns with the relations of constraint it imposes. He also denies the determinism and stability of structures, but maintains the notion that the sense of more personal and transparent actions does not belong to the subject who makes them, but to the whole system of relations in which and by which they take place (Bourdieu et al., 1990).

However, the assumptions and the concept of *habitus* of Bourdieu (2001), as well as the aspects that characterize different sociological fields, do not explicit the notion of the subject, according to Charlot (2009), i.e., a sociology of the *subject* (in this case, it is about the student) which would be capable of confronting the needs of learning, and with the presence of various kinds of knowledge in their world. For the author:

The awareness is a necessary condition for social change [...]. However, while in Paulo Freire, awareness may be an effect of education, in Bourdieu it cannot happen at school, a place where the ruling classes exercise their symbolic violence and "cultural arbitrary." Awareness can only be produced in social struggles. Therefore, the activity is transforming principle, but it is the activity developed in the social struggles and not the activity of teacher and student in the classroom. In fact, Bourdieu is not interested in school activities, for what happens in the classroom, but the social functions of the school, the process of social reproduction through it (Charlot, 2009, p.90).

In the case of the teacher, says Charlot (2005), the problem of teaching is neither only to transmit, nor to make the knowledge be learned. But it is, through knowledge, to humanize, socialize, and help a singular subject to happen. It means to hold a certain part of human heritage. It is to be oneself, an original exemplar of whom is sought to make happen: a man or a woman. The teaching practice is constituted in the living aims of teachers' and students' competence. It is impossible to conceive the knowledge and the different theoretical conceptions about teaching from a separation between teaching contents and ethical education of students. Freire (2002), in the same direction, refers to the notion that the teaching practice is inconceivable without the students.

Thus, it is intended that the knowledge developed in the investigative process of educational practices *with* and *within* PE incorporates the thoughts and actions of those directly involved in these practices: teacher and students.

Physical education: knowledge without subjects?

From the mid-1980s, some theoretical and methodological conceptions in the area of PE were elaborated in an attempt to break with the mechanistic, sportive, and traditional model that supported the intervention in Basic Education, which epistemological frameworks from psychology, philosophy, sociology, health studies, anthropology, among others.

Historically in PE the subject has been relegated to the background, due to the fact that some propositions considered the movement more important than the movement's subject him/herself. None of those propositions made clear or explicit guiding paths to know whether what is *learned* by students in PE classes, or, in terms of Charlot (2000), whether the knowledge of PE are legitimated knowledge by the students.

In this sense, we feature the propositions based on the concepts of "Body (or Corporeal) Culture" (Soares et al., 1992) and "Culture of Movement" (Kunz, 2006).

The term "culture" was literally incorporated by the PE, something that could not be imagined if one considers the history and prevalence of biological sciences in recent decades, demonstrating the influence of the Humanities in the area, according to Daolio (2007). For Geertz, American anthropologist and one of Daolio's references (2007, p.7):

Culture is the very condition of life of all human beings. It is the product of human actions, but also a continuous process by which people give meaning to their actions. They comprise a unique and private process, but it is also plural and public. It is universal, because all humans produce it, but also local, since it is the specific dynamics of life that means what the human being does.

In the view of a collective of authors that proposes an approach called "critical-overcoming" (Soares et al., 1992), drawn on historical and dialectical materialism, PE is a school subject that pedagogically deals with issues of the body culture (games, gymnastics, wrestling, acrobatics, mime, sports), and it is this knowledge that constitutes the contents of PE. But there is one shortcoming in such conception, because it is not clear how the subject appears or manifests him/herself in the movement.

Kunz (2006), in proposing a pedagogical discussion, based on phenomenology, provokes us to try to answer the question: What is the PE that is taught in school? The author's ideas consist in a pedagogy called "critical-emancipatory" which proposes to establish themes, explain and promote educational dimensions of human movement that allow students to construct subjective senses/meanings in the game, sports, fighting, gymnastics, dance, etc., from the concept of the Self-Movement (*Sich Bewegen*):

Human movement as a "Self-Movement" is a relational phenomenon of the "Human being-(in the)-World," and manifests itself always as a kind of "dialogue". One of our best relational languages in different social-cultural contexts, therefore, takes place *via* movement. Exploration and development of this language opens unpredictable and impressive horizons, especially among children and youngsters in the life of relations not only professional relations but especially affective, emotional and sensitivity toward nature and culture. Working with the teaching of human movement that leads to imitation and copy is to suppress and even eliminate feelings, emotions and the important achievements of a person's life (Kunz, 2006, p.21).

In an attempt to break with the traditional concept of physical movement, of the machine that moves, often present when one is trying to understand and define the object of knowledge in PE, the author proposes the concept of Self-Movement that characterizes the very intentionality of the movement's subject.

THE RESEARCH OBJECTIVES

As a general objective we seek to understand how students attribute meaning and make sense to their relationship with knowledge elaborated *with* and *within* PE classes. And specifically: (i) identify and interpret which knowledge is elaborated by students *with* and *within* PE classes; (ii) identify and interpret what relationship they establish with the knowledge from the experiences of learning in PE classes, and; (iii) explain, analyze and interpret what is knowledge *with* and *within* PE in the perspective of subjects (teacher and students) interwoven in a shared educational practice.

The ways of the research

It is a research of qualitative nature, which paradigm, in Education, began to be built in the late-1960s and have been intensified in the following decades, when one could perceive a concern to give meaning and diversify both philosophical foundations that supported the research, and the methods and procedures (André, 1995).

Despite such increase in interest, the distance between the objects of research developed in the universities and the objects of the teachers' concerns about their own work in partnership with their students were slightly reduced.

Franco (2008) warns about the scientific practice of educational investigations and points out that educational theories often fail to translate the senses and to express the meanings that are implicit in the researched daily practices. Therefore it is not always that research impregnates teachers' know-how with comprehension, and do not facilitate their use to enrich the educational practices and actions. Then, research cannot be appropriated by the subjects and therefore cannot stimulate or potentiate changes. This situation, combined with other circumstances, caused a continuous and constant gap between educational theory and educational practice.

In concordance with Alves-Mazzotti (1999), the main feature of qualitative research is to follow the "comprehensive" or interpretive tradition, i.e., based on the assumption that people act according to their beliefs, perceptions, feelings and values and that behavior always has a sense, a meaning that does not happen to be known in an immediate manner, needing to be unveiled.

The proponent of this research, who calls herself teacher-researcher of their own practice (or *praxis*), during a period of time-space of four (4) years made a collective and collaborative intervention with a group of students from a local public school in São Paulo. The background consisted in PE classes, supported by the principles of action-research (Elliott, 1998; Thiollent, 2005) and the notion of "teacher-researcher" (Geraldi et al., 1998). The concern was, at the time, to systematize the curricular principles – objectives, contents, teaching strategies, and evaluation criteria and assessment instruments – that would allow the construction of autonomy in relation to her educational work, as well as elaborate and share knowledge with students which could get them to intervene in their own realities.

Aspects of such education practice based on action-research references have been disclosed in Education and PE scientific meetings in national and international contexts (Venâncio, 2007, 2009; Venâncio et al., 2010),

using part of the systematized records of classes made by the teacher and students, who will also be a source of analysis and interpretation in this research.

In this research, we intend to explain such path and interpret how the subjects have established relationships with knowledge *with* and *within* PE classes. Obviously the researcher, under the condition of teacher, was one of the subjects involved in those relations, therefore she affected the educational processes triggered, and was affected by them. The question that we must ask now is to identify *whether, how, and to what extent* the students involved recognize and assess their involvement in work, and how they were affected by it. Or, in other words, wheter, how, and to what extent they *became subjects toward the relationship with knowledge*.

We are going to use the technique of "focus group" that, as stated by Gatti (2005), has been widely used in qualitative approaches in social research, and has been increasingly used also in educational investigation. According to Morgan and Krueger (1993), research with focus groups aims to capture – throughout exchanges within the group – concepts, feelings, attitudes, beliefs, experiences and reactions. The focus group provides the emergence of multiple perspectives and emotional processes, by the interaction context created, allowing the caption of meanings that could be difficult to express with other procedures.

For the focus groups will be chosen male and female students who participated in the educational intervention at Elementary School (6th to 9th grade), held in the period since 2005 to 2008, and who had contact with the teacher-researcher since 2009 (first year at High School), through messages exchanged in social networks of relationships and e-mails. The focus groups will consist of subjects whose characteristics allow the emergence of different positions.

There is the prerogative of a moderator in the groups' constitution, in this case the researcher, who may have one or more observers to monitor and make records of thematic meetings, to facilitate later the data triangulation. The meetings will be recorded on audio or video format, depending on the acceptance of the groups' component with the technologies. The number of meetings will be set in the course of work. Descriptive data will be interpreted as "triangulation" of sources (audio recordings and videos, interviews, data from observations and records of observers, records made by the school teacher and students) and the dialogue/confrontation with theoretical issues in the literature.

PRELIMINARY RESULTS OF THE RESEARCH AND NOTES FOR INVESTIGATION

We have as background the notion of Self-Movement and Culture of Movement, both present in Kunz's critical-emancipatory proposition (2004, 2006), then this research will be developed around the description and interpretation of the pedagogical work carried out by the researcher in a public school. We seek to uncover how the relationships with students' knowledge are manifested and built, based on the ideas of Bernard Charlot (2000, 2005) and Paulo Freire (2002), with respect to the reflections on the knowledge necessary for educational practice with a perspective to appropriate, change and pronounce the world by the subjects.

We can infer that the different PE theoretical and methodological propositions have not realized the real needs of thinking about the movement's subject yet. However, we emphasize the importance of critical-emancipatory proposition, which begins from the perspective of the subject (human being) and his/her intentions established from, with and within the world.

We have also listed possibilities for nearing Charlot's concepts (2000, 2005) concerning relations with knowledge proposed by the sociology of the subject, Freire's (2002) concepts on educational practices, and the concept of Self-Movement proposed by Kunz (2004, 2006).

Even with all the emphasis on aspects that involve the educational research in the XXI Century, the academic and the school fields are still far apart. According to Betti (2009), there is predominance of research *in* the school (*in* school PE) and not *with* the school (*with* school PE). Moreover, there is a need for progress on the empirical characteristics of educational research, to reveal what knowledge the PE teachers do elaborate and that is concerned with a critical teaching that allows students to appropriate the world and their own lives.

We did a survey of dissertations and theses in FAPESP reference databases defended in the period since 2005 to 2009, in order to find out what studies addressed the theme of teaching and educational practices in PE. In seventy-seven (77) research found in the knowledge area of Humanities none focused on PE, and from a total of seventy-five (75) works in Health Sciences the result was the same. Thus, the results further reinforce the need to investigate the everyday educational practices that are held in PE, to foster new theoretical and methodological propositions.

It is true that there is consensus between the different theoretical and methodological propositions regarding the traditional contents of PE, such as play, games, sports, gymnastics, rhythmic activities and wrestling, which must be systematically organized, and receive treatment that would justify the importance of teaching

and learning in the Culture of Movement context. Despite this consensus, it is necessary to raise some questions that remain unanswered with consistent arguments. A first group of questions – guiding the second group – focuses on the following issues: What to teach and learn? What is the significant knowledge? How to teach and learn? How to motivate and mobilize knowledge? What to teach and learn for? What to motivate and mobilize knowledge for? And the second group of questions: What is knowledge in PE? What is the meaning of the student to study (learn) PE at school? What is the meaning of a teacher to teach PE at today's school? What relationship with knowledge do students make while learning PE? What is the meaning of PE?

We chose these questions to guide the focus of research: to describe and interpret how a teacher-researcher and a group of students attribute senses and meanings to relationships with knowledge elaborated *with* and *within* PE classes.

By drawing attention to the shortcomings of the theoretical and methodological propositions, we hope to provoke an intentional movement in the PE's field of intervention at school, because we understand, along with Franco (2008), that they are the result of the teacher education logic apart from the very logic of practices in which teachers could take on the project of autonomy in their practice (praxis). The perspective of praxis, the author points out, is an action that creates new meanings. To do so, we must assume that the search for new meanings and the claim for autonomy are proper to the human being as a subject that is uncomfortable with its incompleteness, according to Freire (2002) and Charlot (2000).

Charlot (2000), while making his way into the classical philosophy, alerts us to the fact that it defines the essence of man linked to *reason*, that is, the very one that allows the being of man as being a pure subject of knowing, fighting passions, emotions, and, ultimately, the body. The concern of the author thus continues, because the inhibition of the body manifestations cuts all subject's bonds with the world off, in order to save only one: the subject's relation – as reason – to knowledge – as *idea*. Furthermore, we believe it is possible to near Kunz's (2006) and Charlot's (2000, 2005) theoretical referential, since the latter defends the subject of knowledge as the one who develops an activity that is proper to his/her own: arguing, verifying, experimenting, willing to demonstrate, probing, and validating.

There is a self in this epistemic relationship, a self immersed in a given situation, a self that is body, perceptions, system of actions in a mutual relationship with his/her world and actions (as the likeability to act, the value of certain actions, and the effect of the acts (Charlot, 2000, p.69).

This activity is also subject's action on the subject him/herself, therefore taking solely the side of the *reason* and knowledge is to endorse requirements and prohibitions concerning him/herself. According to Charlot (2000, 2005) there is only sense of desire, and this assumption could be articulated to the notion of knowledge. Deepening the question about the meaning of knowledge in PE teaching from the perspective of Self-Movement (Kunz, 2006), we would also find the question of desire. In Kunz's ideas, the subject establishes meaningful relationships based on information, knowledge of his/her life history, social and cultural bonds, mobilizing desires and intentions.

Then, we proceed with the questions: Is there meaning in the relationship with knowledge in Self-Movement *within* the culture of movement manifestations – play, sports, gymnastics, dance, and wrestling? Is there sense and knowledge in the relationship with knowledge to identify and understand what limits or constrains the self-Movement possibilities from personal and interpersonal characteristics, which singularize each subject's own body in performing movements? Is there sense and knowledge in the relationship with knowledge *of* and *within* the world?

We assume as hypothesis that there are specific dynamics in the relationship with knowledge in PE's specific knowledge, and that these dynamics can not be dissociated from culture, body, and environment, because we are, ontologically, dealing with a being-that-moves-him/herself *in* the world.

It is possible to find justifications in the literature for non-appropriation of knowledge by students (e.g., interests, and socioeconomic conditions) and arguments which undermine the teaching profession (lack of competence and commitment), either due to the students' lack of mobilization in the appropriation of knowledge, or due to the teacher's lack of relationship with knowledge. However, we have chosen theoretical frameworks that allow us for questioning the fragile interpretations about school experiences, because learning/knowing has not the same meaning for the teacher and students. Charlot (2000) suggests an understanding of what he calls "figures of knowledge" (knowledge-objects, objects, activities, and relational devices) that are intertwined with the relationship with knowledge as an identitary and epistemological dimension.

Our intention is to propose another reading based on one educational practice (Freire, 2002) among singular subjects, seeking to understand whether and how they become subjects before the relationship with knowledge.

The appropriation of the world, the elaboration of oneself, the inscription on a network of relationships with oneself and others – i.e., the learning/knowing – requires time and never ends. That is the time of a story. That time is not homogeneous; it has its own rhythm, significant moments, occasions and breaches. That time interpenetrates other experiences of the subjects in the present, past and future in a social space.

We hope that this investigation will allow revealing themes and problems in the relationship with knowledge, as well as, based on the elucidation of the very logic of practices, forwarding proposals to better organize the collective processes of changing the students' life reality. The preliminary results already point to the need to establish and to explicit didactic-pedagogic principles that support educational practices in PE concerned with subjects (teachers and students) who learn and teach simultaneously. These principles would possibly derive from the reflective and critical standpoint by the teacher-researcher, who questioned the very logic of teacher education and the logic of her own practice, charactering one educational practice with subjects of the movement in teaching strategies. In sum, this research aims to contribute for building an emancipatory pedagogy in which there could not be only a teacher, or only students emancipated, because the emancipation process can only build up together.

347 - External Evaluation of Schools in Portugal: Framework and Results

Carlos Barreira[1], Graça Bidarra[2], Maria Piedade Vaz Rebelo[3]

Universidade de Coimbra (Portugal)
[1]cabarreira@fpce.uc.pt, [2]gbidarra@netcabo.pt, [3]pvaz@mat.uc.pt

Abstract: In this paper we will present the framework for external evaluation of schools in Portugal and an analysis of the main results, seeking to highlight some trends.

The ongoing evaluation process is being conducted by the Portuguese School Inspectorate and has been the subject of several observations, namely from the National Education Council, highlighting the tension between the two approaches used for the external evaluation of schools: the formative approach, addressing school improvement and the summative approach, directed to accountability. It also highlighted the redundancy of some of the factors or sub domains involved, suggested the adoption of an hierarchy for the domains and a rethinking of their weight in the final evaluation.

After the analysis of the results already published in Portuguese School Inspectorate reports covering 960 portuguese schools, it becomes clear that schools often reveal differences in performance, depending on the domains and factors evaluated, and reveals the possibility of interference from the theoretical framework and methodology itself on the evaluation results.

The evidence of a certain regularity of ratings over the years suggests the existence of a differential weighting of the factors, following the purposes of the model. This differential weighting tends to benefit the evaluation of domains not directly related to the school results, such as *Organization* and *Management and Leadership.*

The results presented in this paper may raise further questions concerning the conceptualization of the domains themselves and of the factors or sub domains they include.

Key-words: External evaluation of schools; framework; results; trends

INTRODUCTION

Following the publication of Law Nº. 31/2002 on the evaluation of non-higher education, it was initiated, in 2006, a pilot project covering 24 schools (Ministério da Educação, 2006), which is the source of the external evaluation process of schools in Portugal conducted by the Portuguese General Inspectorate of Education (Inspecção-Geral da Educação). This process has gone through several stages and in this academic year (2010-2011) completes the first cycle of external evaluation of schools which began four years ago.

In the framework of reference used by the external school evaluation (ESE) are taken into account five key domains: Results, Provision of Educational Services, School Organization and Management, Leadership, and Adjustment Capacity and School Improvement (Inspecção Geral de Educação, 2009a; Ministério da Educação, 2006). These domains comprise between two and five subdomains, in a total of 19 factors. The ratings of the five domains and factors are assigned in a qualitative scale with four levels: *Very Good*, *Good*, *Sufficient* and *Insufficient*.

The National Education Council (Conselho Nacional de Educação) has made several opinions on the evaluation reference used in the ESE (Conselho Nacional da Educação, 2008; 2010a, 2010b). In these opinions, it was highlighted the existence of a certain tension between two purposes of evaluation, the formative purpose of school improvement and the summative purpose, the accountability and the responsibility of educational institutions. Thus, it considers that adjustments should be made in the framework of reference of the ESE in order to strengthen the central findings in the domains, and to consider different weights in the domains.

It seems to us, therefore, appropriate to disseminate the main results obtained in this process, presenting a first reading and analysis of published data, trying to show some trends.

METHODOLOGY

The database of this study was obtained from the results published by the Portuguese General Inspectorate of Education in the Reports on the External Evaluation of School for the academic years 2006-2007, 2007-2008 (Inspecção-Geral da Educação, 2009b), 2008-2009 (Inspecção-Geral da Educação, 2010) and 2009-2010 (Inspecção-Geral da Educação, 2011), where are presented, in percentage terms, the obtained marks in the domains of the framework of reference and the ratings assigned to the factors that constitute them. To ease

the data processing, we convert this scale into scores 1, 2, 3 and 4, respectively. The distribution of evaluated schools over this period is presented in Table 1.

Table 1: Percentages of the classification levels assigned to schools according to the domains of the framework of reference (column-percentages per school year)

Ratings	Academic Results Year	Provision of Educational Services	School Organization and Management	Leadership	Adjustment Capacity and School Improvement
Very Good	**2006-2007**	10	14	29	40	11
	2007-2008	4	10	24	32	6
	2008-2009	7	9	23	33	4
	2009-2010	12	13	29	36	4
Good	**2006-2007**	55	63	61	43	48
	2007-2008	56	59	64	52	37
	2008-2009	60	73	67	51	36
	2009-2010	64	70	63	56	46
Sufficient	**2006-2007**	34	22	9	16	39
	2007-2008	37	31	11	15	50
	2008-2009	33	18	10	15	54
	2009-2010	24	17	8	8	47
Insufficient	**2006-2007**	1	1	1	1	2
	2007-2008	3	0	0	1	7
	2008-2009	0	0	0	1	6
	2009-2010	0	0	0	0	3

For each academic year, the score was calculated for each domain by weighting each value of the scale with the percentage with which the domain appears in Table 1 being these values represented in Figure 1. This procedure was also used to analyse the ratings of the factors and their relationship with the domain. Under this analysis, we calculated the average value of the differences between the ratings of each factor and the domain rating. These values are shown in Tables 2 to 6, where the second column represents the value of the rating of the domain and the following columns the difference of rating in the respective factor, presenting the average of the absolute differences in the last row of the tables.

RESULTS

Ratings in the domains
The rating assigned to the different domains that comprise the framework of reference, over the observed academic years (see Table 1 and Figure 1), points to predominance of a positive rating levels of Good / Very Good, with the exception of the domain *Adjustment Capacity and School Improvement*. This trend has not only remained the same, as it has been growing, with the exception of the academic years 2007-2008.
Despite this trend, there are variations depending on the domains. Indeed, the *School Organization and Management* and *Leadership* are those which get a higher percentage of the rating levels Good and Very Good The domain where these levels are lower is the *Adjustment Capacity and School Improvement*.

Figure 5: Data analysis flow chart
Figure 1: Evolution of ratings in the domains

It is also possible to verify that the ratings in the domain of *School Organization and Management* are much alike with the ones obtained in the domain of *Leadership*, while the ratings of *Results* are close to the domain of *Provision of Educational Services*.

These data raise the possibility that the interpretation of the goals of School Improvement and Accountability of the model itself may be driving to a linkage between *Results* and *Provision of Educational Services*, with the removal of the rating in relation to the other domains.

Ratings *of the factors*

The analysis of the ratings of the factors that characterize the domain *Results* and its evolution, as well as the value of the difference between the rating of each factor and the rating of the domain (see Table 2), shows that the average rating of the *Academic Success* factor has consistently lower values than those obtained in the domain, while the other factors, particularly the factor *Behaviour and Discipline* have a higher average ratings than those obtained in the same domain. That is, the difference of the value between the ratings obtained in the factors and the rating obtained in the domain varies depending on the factors, verifying that the minimum value of that difference corresponds to the factor *Participation and Civic Development*.

Table 2: Ratings averages obtained in the domain *Results* and the differences between the ratings in the domain and the ratings on each factor

| Academic Year | Domain | Factors | | | |
	Results	Academic Success	Participation and Civic Development	Behaviour and Discipline	Valorisation and Impact of Learning
2006-2007	2.74	-0.18	0.18	0.49	0.20
2007-2008	2.61	-0.25	0.20	0.37	0.19
2008-2009	2.74	-0.21	0.02	0.26	0.16
2009-2010	2.88	-0.26	0.03	0.12	0.16
Average of absolute differences		0.23	**0.11**	0.31	0.18

When we consider the ratings of the factors included in the domain of *Provision of Educational Services* (see Table 3), it appears that here too there are factors whose average ratings are consistently lower than those of the domain, namely the factors *Coordination and Monitoring* and *Teaching Practice Supervision*, while the factors *Differentiation* and *Supports* and *Curriculum Support and Knowledge* always present higher average ratings than the observed in the domain.

Table 3: Ratings averages obtained in the domain Provision of Educational Services and the differences between the ratings obtained in the domain and the ratings obtained on each factor

| Academic Year | Domain | Factors | | | |
	Provision of Educational Services	Coordination and Monitoring	Teaching Practice Supervision	Differentiation and Supports	Curriculum Support and Knowledge Enhancement
2006-2007	2.9	-0.14	-0.55	0.34	0.19
2007-2008	2.79	-0.27	-0.42	0.39	0.24
2008-2009	2.91	-0.29	-0.61	0.30	0.17
2009-2010	2.96	-0.27	-0.46	0.26	0.26
Average of absolute differences		0.24	0.51	0.32	**0.22**

Regarding the domain *School Organization and Management* and related factors (see Table 4), we verify that the factors of *Human Resources Management* and *Equity and Justice* obtained ratings slightly higher than those obtained in the domain itself, while factors *Design and Activity Planning* and *Participation of Parents and other members of the Educational Community* obtained ratings well below the ratings obtained in the domain. The factor, which average rating closely matches the rating of the domain is the factor of *Human Resources Management*.

Table 4: Ratings averages in the domain school organization and management and differences between the ratings of the domain and the ratings on each factor

| Academic Year | Domain | Factors | | | | |
	School Organization and Management	Design/ Activity Planning and Development	Human Resources Management	Financial and Material Resources Management	Participation of Parents and other members of the Educational Community	Equity and Justice
2006-2007	3.18	-0.18	0.01	0.02	-0.35	0.08
2007-2008	3.10	-0.24	0.06	0.00	-0.31	0.12
2008-2009	3.13	-0.23	0.00	-0.13	-0.25	0.07
2009-2010	3.21	-0.27	0.11	-0.04	-0.19	0.06
Average of absolute differences		0.23	**0.04**	0.05	0.28	0.08

In the domain of *Leadership* (see Table 5), the factors *Motivation and commitment* and *Partnerships, protocols and projects* obtained slightly higher ratings than those obtained in the domain itself, while factors *Vision and strategy* and *Innovation opening* present average ratings lower than those obtained in the domain. The rating of the factor *Motivation and commitment* is the factor that matches closely to the rating obtained in the domain.

Table 5: Ratings averages obtained in the domain *Leadership* and differences between ratings of the domain and the ratings obtained on each factor

| Academic Year | Domain | Factors | | | |
	Leadership	Vision and strategy	Motivation and commitment	Innovation	Partnerships, protocols and projects
2006-2007	3.22	-0.12	0.00	-0.09	0.07
2007-2008	3.15	-0.19	0.12	-0.22	0.05
2008-2009	3.16	-0.22	0.09	-0.20	0.17
2009-2010	3.28	-0.22	0.09	-0.36	0.12
Average of absolute differences		0.19	**0.08**	0.22	0.10

Finally, with regard to the factors that constitute the domain *Adjustment Capacity and School Improvement* (see Table 6), we observed both in the domain and in the two factors there are average ratings below 2.5, and the ratings obtained in the factors are close to those obtained in the domain.

Table 6: Ratings averages obtained in the domain of *Adjustment Capacity and School Improvement* and differences between the ratings in the domain and ratings on each factor

| Academic Year | Domain | Factors | |
	Adjustment Capacity and School Improvement	Self-Evaluation	Sustainability and progress
2006-2007	2.68	-0.11	0.02
2007-2008	2.42	-0.08	0.05
2008-2009	2.38	-0.05	0.00
2009-2010	2.51	-0.03	-0.13
Average of absolute differences		0.07	**0.05**

DISCUSSION AND CONCLUSION

The data presented show that in general the schools have achieved good ratings in all domains, except on the *Adjustment Capacity and School Improvement*. We also observed that there are domains whose ratings are consistently higher and very close, namely, *Leadership* and *School Organization and Management*, being the ratings of the domains of *Results* and *Provision of Educational Services* consistently close in numbers. However, these data also suggest the existence of a differential valuing of the domains in accordance with the purposes of the model.

The observation of a certain regularity of the ratings over the years under review, and the fact that the contribution of different factors for the domain ranking varies between them, suggests that, although there is no weighting factors in the framework of reference, and defending that it should exist, it is somehow inherent in the evaluation process, when we verify the ups and downs of the ratings in the factors related to the corresponding domain.

The presented data even allow raising questions about the conceptualization of their own domains and the factors that characterize them. These aspects appeared to us to be of much interest and relevance for further study, which is already underway, on a framework of reference and the effects on evaluation related to ratings in the domains and the factors of the schools under evaluation.

356 - Science Textbooks as Questioning and Problem-Based Teaching and Learning Promoters: Change or Continuity?

Laurinda Leite[1], Luís Dourado[2], and Sofia Morgado[3]

Institute of Education, University of Minho, Braga Portugal
[1]lleite@uminho.pt, [2]ldourado@ie.uminho.pt and [3]sofiamorgado@ie.uminho.pt

Abstract: High-level questioning is the starting stone of Problem-Based Learning (PBL). This student centred teaching approach is especially appropriate for complex themes, as these are more likely to include real life problems. Sustainability on Earth is the Portuguese National Curriculum theme that better fits this criterion. This paper concentrates on the way Portuguese science textbooks focusing on Sustainability on Earth deal with questioning, in order to find out whether they may foster continuity with regard to teacher-centred teaching approaches or whether they rather seem to promote change towards innovative student-centred problem-based science learning. Three Physical and three Natural Sciences textbooks were content analysed with regard to the way they deal with questions and the cognitive level of the questions they include. Results indicate that textbooks: include a considerable amount of questions; use questions in different ways and for diverse purposes; tend to prefer low-level cognitive questions; hardly include problem-oriented questions.

Keywords: Science textbooks, Problem-Based Learning, questioning, Sustainability on Earth

INTRODUCTION

The Portuguese Educational System Law (law number 49/2005, 30 August, 2005) acknowledges science textbooks as an outstanding educational resource. However, research has shown that textbooks are conservative with regard to the way they develop curriculum themes, as they hardly integrate knowledge from educational research and acknowledge curriculum prescribed methodological innovations (Moreira, 2003). Besides, research also suggests that teachers teaching practices are heavily dependent on textbook for what they decide to teach and the way they decide to teach it in the classroom. Thus, textbooks act as if they were the official curriculum that many teachers tend to ignore. Hence, if textbooks are conservative, then they may contribute to teachers' conservative teaching practice.

Research (Figueiroa, 2003) has shown that textbook authors refrain from innovating in their textbooks because they feel afraid that teachers do not feel comfortable with innovative textbooks and may not choose them to be assigned in their school. In-service teacher education would help teachers to understand the aim of educational innovation and would make them prone to accept innovative textbooks. However, availability of innovative textbooks may also make some teacher feel the need of engaging in teacher development courses in order to be able to do the most with innovative textbooks. Thus, writing innovative textbooks would be one of the ways of "breaking the continuity chain" and promoting innovative teaching. On the other hand, success may be greater if teachers that attend in-service courses, can find textbook that are consistent with the perspectives conveyed into the course and that facilitate their task of putting into practice the new ideas or methodologies they learned.

This would be especially important when educational innovations that require major changes in teachers' and students' roles are at stake. Problem-based learning (PBL) is a methodological approach that requires major changes in teachers' and students' roles (Azer, 2008; Leite & Esteves, 2006; Savin-Baden & Major, 2004). In PBL environments, instead of teaching I the usual sense, teachers need to organize learning settings for students to learn on their own (Lambros, 2004). Students, by their turn, need to become active learners, as they will not be taught but rather learn by solving problems (Hmelo-Silver, 2004), that should be as real as possible (Lambros, 2004; Hmelo-Silver, 2004). A consequence of this is that teachers may feel uncomfortable and unsecure towards PBL (Dahlgren, Castensson & Dahlgren, 1998; Gandra, 2001). Besides, teachers may not have a pool of problems or scenarios from were to choose the most appropriate ones to use as starting points in PBL oriented teaching sequences. In this case, high-level textbook questions would become useful teaching aids, as they could facilitate teachers' teaching practices change towards PBL oriented ones.

Following authors like Hmelo-Silver (2004), Lambros (2004) and Azer (2008), this paper assumes that high-

level questioning is the starting stone of PBL. By high level questioning it is meant a process in which someone questions formulates questions that require high-order thinking to be answered. Besides, a question may be conceptualized as an issue put forwards for discussion in such a way that it demands an answer (Ferreira, 2010), even though it does not end with a question mark. Hence, questions compare to problems, as both include an obstacle that needs to be overcome by the respondent or problem solver.

Questioning has concentrated several researchers' attention and being studied within diverse educational contexts and from several perspectives (Wragg & Brown, 2001). Initially, those studies were quantitative in nature and concentrated on the amount and rate of questions formulated by the teacher. Latter on, researchers concentrated on the classroom interaction and on subjects questioning abilities, including issues like types of questions formulated by students and teachers in diverse contexts. Researchers in this area have developed several taxonomies of questions that emphasise differently the cognitive, the procedural and the values components. Dalghren & Öberg (2001) defined a taxonomy of students' formulated questions that combines al these dimensions, that Dourado & Leite (2010) found useful to analyse textbook questioning level. It includes five categories, as follows: Encyclopaedic Questions, demand an unambiguous and non complex answer (e.g., What is the greenhouse effect?); Meaning-Oriented Questions, oriented towards finding a phenomenological meaning of certain terms or concepts (e.g., How are images formed in our eyes?); Relational Questions, focus on the relationship between aspects/features (e.g., How do technological societies influence the ozone layer?); Value-Orientated Questions, demand for a judgment based on some criteria (e.g., Bearing in mind that Portugal has to reach an energy goal settled within the scope of the Kyoto protocol, should this dam be built up?); Solution-Oriented Questions, focus on looking for solution(s) for a (social, environmental, health, economic, etc) problem (e.g., What can be done to prevent the energy crises?).

This paper also acknowledges that PBL is a student centred teaching approach that is especially appropriate for dealing with complex themes that should be tackled from several perspectives in order to be fully understood. Thus, complex themes are more likely to include real life problems, which are required for PBL approaches. As Pring (quoted by Santomé, 1998) would put it, when the problem becomes the focus of the educational action, it determines what competences are required and eventually will need to be developed. Thus, by putting the problem at the centre, the boundaries between school subjects will vanish and cross-disciplinary approaches will emerge.

Among the four Portuguese National Curriculum themes, Sustainability on Earth is the curriculum theme that better fits this criterion. It is supposed to be taught is in the Physical Sciences as well as in the Natural Sciences junior high school science subjects. This fact together with the cross-disciplinary nature of the theme leads to anticipate that it could be approached from a PBL perspective that could develop in a global manner the competences prescribed by the national curriculum (DEB, 2001) for the two subjects together. The ways textbooks develop the theme as well as the way they deal with questioning may be promote or rather impair teachers from doing so.

In this context, this paper concentrates on the way Portuguese science textbooks focusing on Sustainability on Earth deal with questioning, in order to find out whether they may foster continuity with regard to teacher-centred teaching approaches or whether they rather seem to promote change towards innovative student-centred problem-based science learning.

METHODOLOGY

Three Physical and three Natural Sciences textbooks dealing with the theme Sustainability on Earth were selected for the purpose of this study. These Portuguese textbooks were randomly chosen on the basis of the publisher, so that three different textbook publishers (and a textbook per subject and publisher) were taken. In order to attain the objective of the study, the textbooks were content analysed with regard to the way they deal with questions and the cognitive level of the questions they include. All questions were analysed except questions within an activity and end of teaching unit assessment questions. The reason for excluding within an activity questions was that the way the activity is introduced is far more important from a PBL point of view than the way the activity is prescribed. With regard to the exclusion of final assessment questions, it can be argued that although they are relevant from a self-evaluation perspective and can be used for enhancing learning, they nevertheless are not relevant from a PBL perspective, as they come after teaching and learning.

It should be pointed out that one of the textbooks (PS 3) is not consistent with the curriculum with regard to the teaching units it acknowledges. However, in order to get conditions to compare teaching units, the way it develops the theme enabled us to join two of its units and to divide a third one (into other two) and to get

teaching units similar to those suggested by the National curriculum and used by the remaining textbooks in the sample.

Questions were analysed through a checklist that had in part been used in former studies (Dourado & Leite, 2010; Vasconcelos *et al*, in press). In order to increase reliability of the results, the analysis was done by one of the authors and repeated by another author. The three authors discussed discrepancies in the classifications in order to reach a consensus with regard to the final classification to be adopted. In order to compare textbooks, percentage of type of questions per textbook was calculated. Examples of questions classified in the main categories will be given in the next section.

Presentation and discussions of the results

As shown by table 1, textbooks are quite different with regard to number of questions they include, being Physical Sciences textbooks (PS) those that include larger numbers of questions.

Table 1: Number of questions per textbook and subject (f)

Textbook	Number of questions	Number of questions per subject
NS 1	160	
NS 2	46	232
NS 3	26	
PS 1	286	
PS 2	258	924
PS 3	380	

This result may be due to the fact that traditionally PS textbooks include lots of exercises and a few problems fro students to solve or to see how they can be solved. This is not so usual in the Natural Sciences textbooks (NS), which include very different numbers of questions.

Textbooks selected for this study include questions in different places, ranging from the opening of the theme (NS 1, PS 1 and PS 2) end of unit complimentary questions (PS 2). Besides, as shown in table 2, NS and PS textbooks are quite different with regard to the places they include questions. In fact, while PS textbooks tend to concentrate questions throughout the text, after the presentation of the content, two NS textbooks tend concentrate them on the title of the activities and the third NS textbooks does it in the margin of the page, aside from the main text.

Table 2: Placement of the questions in the textbooks (%)

Localization of the questions		NS 1 (n_1=160)	NS 2 (n_2=46)	NS 3 (n_3=26)	PS 1 (n_1=286)	PS 2 (n_2=258)	PS 3 (n_3=380)
Opening of the theme		1,9	0,0	0,0	0,7	0,3	0,0
Opening of Units		0,0	30,4	0,0	0,0	0,0	18,7
Title of sub-units		0,0	0,0	0,0	11,5	0,0	0,0
Title of sections		0,0	0,0	0,0	0,0	0,0	0,0
Title of sub-sections		1,9	0,0	0,0	0,0	0,3	26,6
Throughout a sub-unit or section text	Integrated into the content being presented	6,3	0,0	26,9	11,2	12,4	3,4
	After the content presentation	0,0	0,0	0,0	50,7	77,1	42,4
	Resolved questions	0,0	0,0	0,0	0,0	2,7	0,0
	Aside content presentation	86,9	0,0	0,0	24,1	0,0	0,0
Associated to learning activities	Activities title	2,5	69,6	73,1	1,7	0,3	5,5
	Activities statement	0,6	0,0	0,0	0,0	0,3	3,4
End of the unit complimentary questions		0,0	0,0	0,0	0,0	6,6	0,0

Including questions after content presentation is a traditional way of using questions, which is opposite to the problem based learning way of using questions. On the other hand, three textbooks include questions in the

opening page of the theme. These questions are quite important as they can be used as starting points for a PBL approach to the teaching of the theme. Also, as these questions are usually broad questions, they cannot only motivate students to learn but also promote an integrated learning of the content. However, it should be noticed that these questions are the ones that are proposed by the National Curriculum and are not a textbook authors initiative. Figure 1 shows an example of an opening page of the theme, that repeats the following questions included in the national curriculum: Why are ecosystems in dynamic equilibrium? Haw can science and technology take the most from the use of natural resources? How has Humanity contributed to global change?
Figure 1: Questions in the opening page of a teaching unit (NS 1, p. 7)

On the other hand, it should be emphasized that NS 2 and PS 3 include considerable percentages of questions in the opening pages of the teaching units. Figure 2 shows an example of the questions presented in the opening page of a teaching unit of textbooks PS 1.
Figure 2: list of questions in the opening page of the teaching unit (PS 1, p. 156)

Questions in this category are of the initiative of the textbook authors and can reveal some awareness of the value of PBL. In fact, teachers can use these questions as starting points to learning. They are qualitative, conceptual questions appropriate for students to investigate about issues: What are the main environment problems of the Planet? What is global warming about? (free translations of the two first/top questions in figure 2).

Some textbooks use questions as titles for activities (figure 3). This way of using questions makes it clear for the students what they are looking for when solving the activity. In figure 3, what is the role of the resonance box? It also makes students feel the need for getting an answer, by solving a problem that is, by performing the activity. Therefore, it is consistent with the PBL idea of starting with a problem.

Figure 3: Question in the title of the activity (PS 3, p. 20)

Textbook PS1 is includes several questions throughout the text, but aside from the main text, that seem to aim at raising students' curiosity (Sabias que? or Did you know that?). This type of questions usually inquires students about whether they knew about or had heard about something. Example given in figure 4 asks students about whether they knew about the frequency of human voice and the frequencies that human hears are most sensitive to. In fact, these questions concentrate on particular aspects that are not that important from the school subject point of view but that can be interesting or even relevant from a personal point of view. Nevertheless, these questions do not require high-level reasoning and therefore they are not relevant from a PBL point of view.

Figure 4: Question for raising curiosity (PS1, p. 30)

The places where questions can be found in textbooks when they develop this curriculum theme (Sustainability on Earth) compares to those indentified for the theme Earth in Transformation (Vasconcelos et al, in press). Although textbooks used in the two studies do not belong exactly to the same collections/editors and, therefore, a textbook based theme to theme comparison cannot be done, it can nevertheless be stated that, in the overall, textbook follow similar patterns when approaching the two curriculum themes.

Comparing data given in tables 2 and 3 it can be stated that, in most cases, the place of the questions is directly related to their functions in the textbook.

Table 3: Role of the questions (%)

Role of the question	NS1 (n_1=160)	NS 2 (n_2=46)	NS 3 (n_3=26)	PS 1 (n_1=286)	PS 2 (n_2=258)	PS 3 (n_3=380)
Present expected learning results	1,9	30,4	0,0	12,2	0,4	18,7
Present the text to be developed	2,5	0,0	26,9	1,0	1,9	26,6
Link parts of a text on a given issue	5,6	0,0	0,0	10,1	10,9	3,4
Present compulsory learning activities	3,1	69,6	73,1	1,7	7,0	8,9
State knowledge application activities	0,0	0,0	0,0	50,7	77,1	42,4
Try to keep readers' attention	86,9	0,0	0,0	24,1	0,0	0,0
Show how to solve a problem/exercise	0,0	0,0	0,0	0,0	2,7	0,0

As they are not supposed to be answered at the stage they are introduced, their aim cannot be associated to diagnosing students' ideas on the issues they focus on. Thus, questions in the opening of theme or unit and title of section or sub-section can be better interpreted as presenting learning results as they give students an idea of what they are supposed to learn about. Figure 5 shows one of those questions (How are living organisms organized in the biosphere?) that is associated to a conceptual scheme that gives an overall idea of what is going to be learnt.
Figure 5: Question aiming at presenting learning results (NS 2, p. 12)

Some textbooks use questions throughout the text to link parts of the text or to introduce knowledge application activities. In the former case, the questions help to keep the reader's attention and promote understanding because even they may not be answered, they interrogate the reader about what he/she is reading. Figure 6 shows one of those questions (free translation: But, science and technology innovations are good or bad from the humanity?).

Figure 6: question that link parts of a text (NS 1, p. 202)

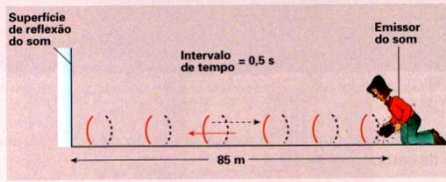
 Application questions are relevant to help students to get feedback on their own learning but as they come after learning, they are not useful from a PBL perspective. Figure 7 gives an example of questions used for this purpose. These questions concentrate on the chemical character of some substances everyday (e.g., orange juice, vinegar or rainwater) or lab substances.


Figure 7: Knowledge application questions (PS 3, p. 121)

Some textbooks also include questions to show students how to solve problems/exercises. Figure 8 shows a question that requires students to calculate on sound speed. This type of questions aims at developing students' exercise solving skills. Although some of these skills may be relevant for problem solving, these questions are not relevant from a PBL point of view, as they require previous knowledge that is available only after teaching.

Figure 8: Question used to show to solve a problem/exercise (PS 2, p. 31)

With the exception of the NS3 textbook, most of the questions are encyclopaedic or meaning-oriented questions (table 4). The former requires rote learning, has no relationship to problems and is not relevant from a PBL perspective. Meaning-oriented questions require understanding and therefore they can be useful within PBL approaches even though they do not require very high reasoning levels. The other three types of questions are much more interesting as they require high level reasoning, namely the establishment of relationships, the making of judgements and the drawing of solutions for problems. Examples of the diverse types of questions were given in the introduction section of this paper. It should be noticed that a few questions were not classified into the five main categories as they were not well formulated and could not be understood well enough to be classified into those categories.

Table 4: Cognitive level of the questions (%)

Category	NS 1 (n_1=160)	NS 2 (n_2=46)	NS 3 (n_3=26)	PS 1 (n_1=286)	PS 2 (n_2=258)	PS 3 (n_3=380)
Encyclopaedic	90,0	13,0	19,2	60,8	58,1	47,6
Meaning-oriented	8,1	67,4	42,3	37,4	41,5	49,5
Relational	1,3	15,2	3,8	1,7	0,0	2,4
Value-oriented	0,6	0,0	0,0	0,0	0,0	0,0
Solution-oriented	0,0	2,2	34,6	0,0	0,0	0,3
Other	0,0	2,2	0,0	0,0	0,4	0,3

CONCLUSION

Textbooks differ with regard to the amount and the way they use questions, being NS textbooks quite similar among them but a bit different from the PS ones. PS textbooks tend to emphasise application questions while NS textbooks tend to emphasise question oriented activities. On the other hand, with the exception of the NS 3 textbook, most of the questions included in the textbooks analysed are encyclopaedic or meaning-oriented questions. Thus, textbooks questioning might not be too much helpful if a PBL approach to Sustainability on Earth is to be put into practice. Textbook authors seldom suggest their own questions as starting points to content development. Taken together, these results indicate that teachers need to find out problems or to prepare scenarios if they want to apply this innovative student-centred teaching approach to the content theme that is at stake. In addition, as the Portuguese curriculum is not a Problem-Based Curriculum, then teacher education is needed in order to help teachers to integrate PBL in a competence based curriculum without failing the development of students' prescribed competences.

361 - Photographic Images of Teachers: a Visual Journey of Teachership in Municipal Schools of Rio de Janeiro in the end of the 19th Century and Beginning of the 20th Century

Ana Valéria de Figueiredo-da-Costa

University Estácio de Sá; PUC-Rio; SEEDUC/RJ; University Iguaçu
anavaleria_figueiredo@yahoo.com.br

Abstract: This work aims mainly at investigating, through photographic records and reproductions, the social relations and customs which emerge from the analysis of images of Rio de Janeiro's municipal school teachers, during the period between the end of the 19th century (the 1890s) and the beginning of the 20th century (its initial decades). By analyzing how the images of the teachers was made public and attached to values through photographic documents, reflected in everyday school practices of the period investigated, the work took the form of a historical-sociological study. This search for meaning in the visual discourse of the photographic images analyzed allowed the mapping of the everyday pedagogical customs of these female teachers who imprinted their identities. The structure used to analyze the photographs was based on the premise which also defines photography as a *visual text*, benefiting from the theoretical leads laid by Boris Kossoy, Ana Maria Mauad, Lorenzo Vilches, Ruggero Eugeni, Erwin Panofsky, Roland Barthes, among other authors cited. The city of Rio de Janeiro was chosen because it was the country's capital until the year 1960, besides the fact that, nowadays, it remains a broadcasting hub in terms of habits and customs which spread throughout the country, having, therefore, welcomed and emanated official modes of professional conduct; in the case of this thesis, the identity of female schoolteachers. The final considerations of the work point out that the study of images and photographic documents of Rio de Janeiro's elementary public school teachers offers a new look on the construction of the teaching identity, on the networks from which this identity is woven. These images do reflect the facts as well as the ideologies of the periods in which they were produced, recorded and made public. They can only be analyzed if today's audience is permeated not only by the time in which it lives, but also by the context in which these photographs were taken, which opens the way to a dialogue between the record and the view of the contemporary observer.

Keywords: photography – teachers - 19th century

School teaching has been a source of different studies and thesis throughout time. It has been a tool for doctrines and freedom, depending on the point of view and the thought of different times and social groups that think and operate on it. In this sense, to think about education is not ever to take up a neutral position, innocuous or without commitment.

It hasn't been any different in Brazil. Since the times when school education had been done primarily, and why not say, exclusively by Jesuits, this battle field already showed itself as fertile and of difficult decisions. And thus it continued [and it continues] throughout the centuries.

In the imperial times in Brazil, even though there was, with Pedro II, a slight interest in widening school education, this interest was more strenghtened by political issues and the Emperor's image than say the actual interest in educating the people. With the Proclamation of the Republic, this scene changed.

The research Photographic Images of Teachers: a visual journey of teachership in municipal schools of Rio de Janeiro in the end of the 19th Century and beginning of the 20th Century, my doctorate thesis investigated, through photographs, in what way the image of municipal school teachers of Rio de Janeiro was built and represented, concentrating on the period from the end of the 19th Century (1890) and beginning of the 20th Century (1930), period of the History of Brazil known as First Republic or Old Republic.

The option for the proposed period for investigation was due to the fact that during the Old Republic, period highlighted by historians and also known as First Republic (from 1890 to 1930), that an ideal came up for a strong, civilized Brazil which would be achieved by Order and Progress. The school and its teachers would be leading people in the construction of this victorious architecture.

It is important to mention that this paper has as background, aspects of Cultural History by understanding that objects from the day-to-day life – in this, specifically the photographs -, are contributors of a time in which its use and customs tell us about the ways and manners of back then. It is by knowing the past that historical meanings can be established and the social function of the present can be understood. Therefore,

knowing the school and its people is also to recognize that we are too constructors of a time that is recorded in the image and in the folds of time of times.

Image is communication. Since prehistory, with the images engraved on the walls, the image is a fascinating object of amazement, identity, message. Nowadays, in the so-called *post-modern* time, even being virtual, created in a space-time of imaterial concreteness, the image is the translation of stories, desires and the establishment of symbols and icons, patterns of how to live and view life.

The work happened as a historical and sociological study, and it searched messages on the photographies of such period, habits and customs represented by the image of the primary school teacher, in which the main text is photography as *visual text*, as some authors point, such as Leite (2001), Kossoy (2001, 2002); Amount (2000); Panofsky (2002); Joly (2001), among others mentioned throughout this paper.

Therefore, studying images, photographic documents of the environment of public schools of Rio de Janeiro, makes a way for us to reach into a new perspective on teachers' identity construction, as well as where this identity is woven and modeled, considering these images are not distant from the events and the ideologies that were produced, registered and distributed during their time; the spectator of our time too cannot analyze these images without being saturated by the time in which he lives, and this opens up a way for dialogue between the record and the view of this current observer.

Searching for keys to analysis of the visual text

Panofsky (2002) presents us with a list of methodology steps to engaging in reading visual arts, to which I include photography. The steps are such as it follows:

> the first step concerns the observation and examination of the material; it is a basic step of approaching what the researcher has collected and has in his hands, so that it might be complemented, if necessary;
> the following step consists in decoding and interpreting the records that were collected;
> the third step is to categorize and coordinate the material into a coherent system, that "makes sense".

The first and second steps are denominated by Panofsky as "factual meaning" (primary or natural, according to the author), or in other words, the meaning is "aprehensed by simply identifying some visible forms with certain objects which I already know by practical experience and by identifying their change in relations with certain actions or facts". The third step is called "expressive meaning" (secondary or conventional, idem), and in order to comprehend the image, sensibility is needed, together with references which I join to what I see in order to better understand the object in analysis (id., p. 48-49).

In summing up his considerations, the author presents the following chart (2002, p. 64):

Objet of Interpretation	Interpretation Action
I – Primary or natural Theme A – factual B – expressive	Pre-iconographic Description (and pseudo-formal analysis)
II – Secondary or conventional theme, consisting of the world of images, stories [sic] and allegories	Iconographic Analysis
III – Internal meaning or content, consisting of the world of "symbolic" values	Iconologic Interpretation

The layers organized in the chart by the author are just instructive, illustrative. It is so that he says

> we have to bear in mind, though, that these three clearly different categories, that in the chart seem to point to three independent spheres of meaning, in reality they relate to aspects of the same phenomenon, being it the piece of art as a whole (id., p. 64).

The author's reminder is essential to image reading, and it is not advisable to separate the analysis of technical aspects from the symbolic aspects. In what concerns photography this becomes even more pertaining, due to the fact that photography is a mix of technique and art, even more so in its origin, such is the case.

Based upon these considerations, both technical aspects and cultural code aspects are important in reading a visual text. Therefore, when the author says that "the man who is run over by an automobile, is run over by mathematics, physics and chemistry" (id., p. 43), in what concerns photography we can understand that

whoever reads the photographic image, besides paper and the development technique employed, also reads codes and symbols of the reality recorded in it.

What the photos "say" to us...

As I have been pointing out throughout this text, the analysis proposed here of photography as visual text does not strongly support itself on technical aspects, but it cannot ignore such aspects in order to be complete, and therefore it becomes important to learn about forms and frames of photography. The fact that a message has as function to communicate contents that were chosen by the one who creates it is agreed upon. Such content needs a certain organization so that it might be clearly understood by the spectator, or at least, it might put limits to the width of how the message can be understood.

With the visual text, this point is more critical, if we consider its polysemy and multi-interpretative nature. As Dondis (2000, p. 134) advises, "in visual terms, our perception of content and shape is simultaneous. It is necessary to deal with both as a singular force that carries the information through in the same way. [...] What you see, you see".

It is by the shapes that the message sender might have some success in controlling the direction and the effectiveness of the message that he wants to transmit. In photography as visual text, these shapes are there too, whether the photographer is aware of them or not. When people and objects that are photographed are organized this or that way there is a logic of shapes and structures: why is the building more evident than the people in the picture? Why are there people seated in the picture while some are standing? Why is there an object showing on the right side of the picture? Why? Why?

Listing the *whys,* we see the need to seek after a key to analysis, which, as the author mentioned above states, is not only found in the content, but also in the shapes and in what way they were spatially organized in the photograph, conceiving a visual text: "seeing is a natural fact for the human organism; **perception takes a process to become capable**". It is necessary to perceive the shapes, understand them in its spatial organization so that the message might be more comprehensible: "in its [visual] composition, the first step is based upon a choice of proper elements pertaining to the communication mean with which you are working. In other words, **the shape is the elementary structure**" (Dondis, id., p. 136-137; my own highlights).

If, as the author says, the shape is elementary, in what way do they appear in the visual text in what comes to a photograph? Seeking a certain shape has to do with the message function intended by the sender. Thinking, for instance, about the pictures of teachers and their students, we join the recorded elements to the context of order and civility to which the school was recipient in the end of the 19th century and beginning of the 20th century, these pictures intended to show hierarchy in a well and properly organized arrangement. It is not without reason that the National Flag is behind one of the teachers, as we see in the following picture at Joaquim Manoel de Macedo School.

Picture # 1: Joaquim Manoel de Macedo School – 1920 (on the black board)
(Without authorship)

Dondis completes her statement mentioned before by saying that the visual image, here the photograph, "needs to represent and reveal its final aim. Not only through words or symbols, but through its **whole composition**" (id., ib., 138-139; my own highlight). Thus, when you look at the previous picture, the hierarchic order and organization is noticeable in it as a whole.

On the other side, without being separate from the sender, we find the receptor of the message, the spectator, the one to whom the image-photograph is made. Martine Joly calls it "the expectation of the spectator of the time" (Joly, 1996, p. 62). The author says that there is a game of announcements, signs, manifestations that can be seen or not, references and familiar characteristics which the audience expects to receive, or in other words, there is a way of receiving the image that characterizes a certain audience in a certain context.

This refers us to the Brazilian Modern Art Week, which happened in São Paulo in 1922, in which visual artists, musicians, writers were severely mocked and criticized because of their modern arts that, nowadays, we look at, listen to and read without being shocked, recognizing their avant-garde elements that caused agitation at the time. As to photography that was produced during the same timeframe, with its reliability status, it had to show the seriousness intended for the time, picturing elements in an intelligible way to its intended audience: families, authorities, students, and spectators at last.

The shapes can be perceived in different ways according to the organization shown in the photos. Ostrower (1998, p. 84) makes the following comment about shape and its perception "due to the simplicity, regularity and symmetry found in the structure of the circle, the square, and the triangle, these geometric designs were considered as having a 'good' configuration" by perception researchers of the 19th century. I do not think it is by chance that many photos of this study show these elements in their composition and they are dated from the end of the 19th century and beginning of the 20th century.

Among his considerations about shapes and their expressive strength, Ostrower (id.) says that the circle concentrates an energy field from its central part, from where forces are sent out and are limited by its border.

Photo # 2 – Prudente de Moraes School – 1930's
Literary Session (Augusto Malta)

This is a photograph by Augusto Malta dated from the 1930's. We can observe that the circle disposition concentrates the attention in a ways of keeping the look going round the group. The force of the shape makes us look at the circle in a circling manner, concentrating the look on its limits, which are its strength: the propaganda of the "literary session". This circling look sees in the center a girl standing up, which re-enforces the circle and its limits, and it sees the people seated as its rays. This way, whether we look at the people, or at the girl standing up in the middle, the circle idea remains, suggesting movement in reading, even though the people are seated and "still".

According to the same author, the triangle is also a shape which, according to its disposition, it might give us the impression of stability, or the opposite. When it is based on an horizontal line, the triangle promotes the impression of stability with a firmly planted basis; on the opposite side, with its tip based on the horizontal, giving us the impression that it is "upside down", it brings the impression of lack of balance.
Photo # 3 – Getúlio Vargas School
Panamericano Club – 1935 (without authorship)

If we take the floor where the table and the feet are standing as the base of the triangle, and its "tip" as the tip of the flag, we can perceive that the group is inside this area in the picture. At least apparently, there is no agitation in the picture; quite the opposite, we can see self-restraint, order, concentration.

The wish for global balance, as Ostrower (id.) points out, is directly related to the author's own personality and to his own concept of "fair and balanced". There will always exist evaluations that overtake rational intelectual options, in choosing what should be recorded. Actually, when the photographer captures an image and chooses it to be registered, he is giving his own opinion about a determined topic.

The author mentioned above says that the choice "will always be an intuitive and sensitive knowledge that manifests itself starting from existential values and also due to the multiple simultaneous differentiations and formal relations and to the complexity of tensions (spatial and emotional)" (Ostrower, 1998, p. 96). Through this point of view we can support and explain the fact that there are multiple meanings to the visual text. The author completes her idea by saying that "the person who stablishes the parameters for our evaluation is the author who created the images himself" (id., ib., p. 206). From this mixture that concentrates rational choices as well as sensitive choices, the piece of art if the visible product of the author's concept.

The proportion in distributing the elements that are photographed is a centerpiece in the content of the intended message. The arrangement and the relation among the parts inside the total conjugate the spatial dimension through which "the whole set becomes the *context of its components*" (Ostrower, 1998, p. 219; highlight in the original). In arranging the elements to be photographed, the author of the photo will have organized the message according to his internal coherence – the balanced parts -, besides the external coherence that gets shown to the eyes of the spectator.

The arrangements are expressive and they are a response to some physical, spatial, thematic issue. This way, "the choice for a certain proportional pattern was determined many times by the cultural context in which the artist lived, depending also on the purpose of the piece of art [...]" (id., ib., p. 233). In seeking balance, the choice for how to arrange the photographed groups is also *properly* tidy, or in other words, they are in accordance to the author's order and his time order, and they are never separate from each other.

What should remain is the fact had the polysemy of the visual text is not an excuse for its inexistence; there is a need to seek, time and time again, more elements that base this reading, opening possibilities for a specific kind of knowledge that is non-verbal, but it is imperative in the current time, as it was before the invention of writing.

The interpretation process is cyclic, dynamic and built step by step, according to the interpretative process, that re-takes and re-elaborates the constructions of previous cicle or of the same cicle, formalizing a logic analysis. Through this idea, having the pretension of ending an analysis through a first and quick look is to give the interpretation in to thoughtlessness, considering that the interpretative process assumes many succeeding approaches to the object in analysis, turning it into cycles that complement each other and enlarge the frame of the look. This point brings up how important it is to improve the look and see into the stated and the non-stated, which complement themselves in the dimensions and analytic levels, such as the author mentioned before advises us to do.

Thus, let us take, for instance, the following photo:

Photo # 4 – Marechal Hermes School – 1915
(Without authorship)

At a first look, we see a group of women seated in front of a staircase, where we see three people leaning on the banister. Looking at their clothes, we can see the restraint, even for the time of the photo, dated from 1915. Their countenance are serious, concentrated; some of them look at us directly, others seem distracted, looking afar.

When I join in the information that they are a group of teachers, this description takes up another meaning and perhaps it is more clearly understood why they have such serious looks and why their clothes are modest: as well known people in the society at the time, the teachers had to symbolize the order for the progress of the nation through children's education and, therefore, they were not supposed to have any sort of caprice, and even less so seductive looks in their countenance, gestures and clothing.

Enlarging the first description even more, if I say the entrance where the teachers are seated at is at Marechal Hermes School, in a suburb called Botafogo, South wing of the city of Rio de Janeiro, the first school especially built for children, we can understand more clearly that the location for this picture was chosen and carefully thought of to be preserved for posterity, since this school was novelty in terms of architecture and construction of schools back then.

FINAL CONSIDERATIONS

The representations are linked, or in other words, they are produced starting from the mixture in which are blended political, individual and social practices, besides discursive, and others. They do not act or produce themselves alone; they are integrated and, when there is any movement it always re-shapes the other parts of the structure as well. Concerning the photos analyzed here, with the upcoming of new social republican values, the school, and consequently the teachers' work, had suffered alterations and, to support the politic-social demand, new representation models had been established.

In this thread we find two axes that intercross and feed each other permanently: a long ax, the diachronic and the short and punctual ax, the here and now, the synchronic. The structures are maps through which we approach an object of study. This was one of the reasons why I used photographs in order to understand chains of visual texts, with both continual aspects and unique ruptures.

The photograph makes postures, conducts, models popular, in order for them to be social and professional parameters, in the teachers' example, mainly when we talk about official photos, such as Augusto Malta's photos. Why was that moment photographed? Why was the moment so important and to whom was it important? Perhaps this explains the constant appearance of "important people", authorities in the photos of the school and its events.

The show-off and the publishing of classrooms became an excellent teaching propaganda of wide range. The use of teaching-pedagogic material was a mark of the modernization and remodeling of Brazilian education. Persuasion through esthetics replaces the old ferule. If the lesson was taught by hand before, in the new teaching methods that were to be put into practice a more voluntary and willfulness move was necessary, achieved by the pleasure of being in the school, participating as a whole, not just with their hands spanked.

The photograph shows the individual, and therefore he actually comes into existence as an *individual*, since it is now possible to prove his existence empirically through the picture. Taking the photos of the teachers,

for instance, if it is possible to prove the order, the organization, the modern school practices, then it actually exists, it is reality and whatever drifts away from this empirical model of *truth* is just illusion, mirage. Therefore, a photo is never an innocent picture; it is a choice that intends to register and to leave the time's seal for "eternity"...

369 - A New Exportation of Technology Island: Inquiring the Science Background Parents Expectations in Science Curriculum of Waldorf School in Taiwan

Chin–ya Mai

National Taipei University of Education Curriculum and Instruction Institute

maiyaya1128@gmail.com

Abstract: Taiwan, as known as one of the leading country of the world in high technology industry, is the heritage Original Equipment Manufactures provider with high quality for years. Also, Science Education in Taiwan had nurtured a group of victors in the International Mathematic Olympiad (IMO.) Furthermore, Hsinchu Science Park which locates in Hsinchu County is known as a science city which nurtures a quality investment environment conducive to the national economy. These years, there are several primary schools intend to do some changes on their educational approach. Some of them locate exactly in Hsinchu County; one Waldorf kindergarten, two new established Waldorf elementary schools in the past two years. What is more, National Hsinchu University of Education, one of the famous educational universities in north Taiwan, had started provided training program for becoming a Waldorf teacher. The main purpose of this research is try to use literature review to find the position of science education in Waldorf educational curriculum which concern in the relationship between human development and natural environment. This research used narrative inquiry method to interviewing the parents who work in Hsinchu Science Park would be a plus benefit to this research; by the result would be able to show the reason of why these "science people" would like to choose Waldorf educational system for their children and what are their expectation toward Waldorf schools. In the end, this research attempt to model the new values in science education, which build up by Hsinchu science people and Waldorf education community in Taiwan.

Key words: science curriculum, Waldorf education, parents' expectations

INTRODUCTION

Taiwanese students consistently rank near the top on international exams on mathematics and science. In 2007, Taiwan recorded the highest TIMSS math score for eighth grade. The central education agency in Taiwan publishes detailed mathematics curriculum guidelines, which textbooks and national exams follow closely (Jane-Jane & Feng-Chiu, 2011). Most of the children in Taiwan will follow this way to learning in mathematics and science, so that they could have ability to compete with other student in the same age. If we only focus on the high score and competitions, traditional science education style could satisfy parents already. Its not only work in national exam of Taiwan to help students attend to the famous universities, but also let Taiwan get high reputation of Science Education over the world.

But these ten years, some parents change their expectations in Education. They don't want to only focus on competitions, but ignore the basic essence of learn to the world. They found out that face the exams is not a goal in Education. Even though they are born in that generation, which has very heavy stress in study.

In this research I interviewed a parent, who work in Hsinchu Science Park. He is an engineer in Electronics Corporation for years. When his daughter was four, he made a big decision to transfer her daughter to Waldorf style kindergarten instead of a famous bilingual kindergarten in Hsinchu. There is a common saying about "Don't let your child lose at the starting point " in Taiwan. It's popular to sent kids to bilingual kindergarten, because most of parents think that "the earlier child learn, the more they can get." Especially in English learning, get knowledge of nature and study Chinese characters in early period.

I want to inquiry this father's (Papa) life story, which could appearance the life style and thinking way in last generation of some people in Taiwan, in order to understand the thread of his thought that why he want to let his kids transfer to Waldorf Education. And as a science worker in high tech, what is his expectations in the curriculum of Waldorf school, when the mainstream science education not only successful over the international exams and had build up the Kingdom of Technology in the world already. Why he wants to change these for the next generation?

WHAT HAPPENED IN SCIENCE EDUCATION IN TAIWAN NOWADAYS?

With the survey of the "Common Wealth", which is the famous magazine in Taiwan. It shows there are more than 80 percents of Taiwan high school students do not want to become scientists. Comparing with Japan government, who vows to develop mathematicians and scientist is an important national task nowadays. And with Obama announced that he wants to use science education to save the economy in the United States.

The truth is that Taiwan's junior high school students are good at science competitions in the international competitions, like IMO, TIMSS whether in math or science fields, their grades are highest in the world top three. The fact is Our students won the gold medal every year in mathematics, physics, chemistry and other science related disciplines, but for what reason those students don't want to devote themselves to science work in their life?

Let's back to the story in thirty years before. When "Papa" was young, he lived in the countryside with parents. There was nature environment around him let he to explore and play with. He loves to stay with nature, sometimes go fishing by the stream, and sometimes created games with friends in the cultivated lands after school. He didn't spent time at schoolwork and read books during the childhood. At that age, the resources of education in countryside could not compare with the big cities. Not only the hardware like library and instrument of science experiment, but also the software like the qualities of teachers and their design of curriculum and instruction in subjects.

Papa almost spent all the time playing and hardly study during in elementary school. He started to study as he attended to junior high school. Although he didn't know what is his study for, but he just read hard. Just like other students' do in junior high school at that time. If something he cannot realize in the textbook, he would memorize mechanically to prepare the exam. After the entrance exam, he had no idea to choose the career orientations. He didn't know what's his interests, or in other words he neglect to explore which way he want to work with in his life. He made decision to study in the department of electronic. The reason is only in this field he can get a job easily, since there are many electronic OEM factories and companies in Taiwan. He totally neglected what he really wants to do and didn't care about that anymore at that time.

Papa earns his living in the science manufactory, just follow what he study in school. Compare with new generation in Taiwan, these children have sufficient resources in science education and that style of learning could let some of them win the good prices in this field. But the reality is that, most of them still not interest in it and do not want to work with it as a career in their lives. Isn't it ironic and need to inquiry?

THE SCIENCE CURRICULUM OF WALDORF EDUCATION

Waldorf Schools are based on the writings of Rudolf Steiner, the 19th century founder of "anthroposophy." Anthroposophy is an outgrowth of the theosophical movement popular in the early 20th century, a "spiritual" approach to philosophy. The Waldorf approach is infused with "spirituality." But if schools follow Steiner's views on science, education will suffer. Steiner believed that materialism was insufficient for the understanding of nature (Scott, 1994). Modern science totally ignores the spiritual part of the nature. And they fallow the evidence from laboratory, some of that is far from the real world. But most of people believe in the results of that so firmly more than what they really sense of the nature. The foundation of Waldorf Science Education is more concerning the relationship within the human being and nature. That is including the relationship of "Man and the Animals" and "Men and plants" and "Man and whole nature". Those all develop with the real world instead of the lab.

More of that, absolutely fundamental to Waldorf education is the belief that each child is a spiritual being, come to this Earth with a purpose. Equally, as nature itself is the handwork of God, one wishing to truly understand nature, and science, should cultivate a reverential, awe-filled approach to its study. There is a big different in the common sense of that "man can conquer nature" nowadays. In addition to qualities of awe and reverence, a "training of the senses", as it is referred to in Waldorf circles, is considered vitally important to opening the way for intimate experiences of scientific phenomena. Based largely on the work of Johann von Goethe (1749 – 1832), the Waldorf, or Goethean, approach to science is a deeply experiential one, where the belief is that human beings can in fact be participatory observers of life, not merely outside observers. The study of science, therefore, is an attempt at understanding the mysteries of life itself and, as such, that all will be avoided to modern science (Simmons, 2004). But the latter view was popularized by the philosopher Kant, who believed that people were only capable of a kind of rational intellectualism, a view still dominant today, and one which infuses life with a most deadening kind of materialism (Scott, 1994).

SCIENCE BACKGROUND PARENTS EXPECTATIONS IN WALDORF SCIENCE CURRICULUM

Why transfer to Waldorf School?

When Papa was a fresh man. That was the first time he had enlighten by the teacher of calculus in university. From that moment, he started to interest in what he learned after he really understood them. Or before that, he chooses to study in science field just because he was always good at mathematics. After that turning point, he kept study in graduate school in electronic department. Then Papa got the master degree, and then he went to the Electronics Corporation in Hsinchu Science Park.

Papa married with a physic teacher (Mama) of senior high school. Both of them are major in science in university and with master degree in domestic science field. For their first child (Nana), they choose the bilingual kindergarten to her. Wish she could learn more during the preschool education. But Papa found that there was something wrong with Nana. Evan Papa and Mama choose the most famous kindergarten and try their best to provide a wonderful learning environment for Nana. In Papa's mind, he always felt there was something wrong with her daughter. He found out that Nana seems cannot be calm, and her mind and spirit was not floating smoothly in her physical body. This finding is followed Papa's intuition, not for any doctors' advices. Once he survey the blog of his colleague's wife, that was the first time he know the Waldorf Education. The first impression of that survey is a beautiful picture in that Web which was a painting in Waldorf teacher training subject. Papa recalled when he studied in graduated school, that was the first time he found out himself indeed love work in art. It was so late for him to change his major, after he had studied in electronics so long. So that when Papa saw that painting he moved deeply with it and the essay by Steiner called The Education of the Child (1996):

Life in its wholeness is like a plant. The plant contains not only what it offers to external life, but it also holds a future state within its hidden depths.

After that encounter with Waldorf Education, Papa fallowed the description of Steiner's books to change the way to provide another kind of environment to Nana. He didn't let Nana watched TV and use computer anymore, although Taiwan is keen to develop the electronic media to support education in any period of school. That is popular to let children watch the Discovery Channel to absorb the science knowledge at home, not to mention that there is 24 hours cartoon TV programs could be the company with children, which do a big favor for busy parents' to manage their time easily after their over time working life.

That will be a myth not only in life style but also in education, that using electronic instruments is symbolizing advancement. When Papa never turns on the TV in front of his child, Nana was changed. Papa observed Nana could coordination with her mind and body better than before. From this moment on, Papa wanted to transfer Nana to Waldorf style kindergarten, what is more he wish Nana could learn in Waldorf School until 12 grade.

The expectations of Waldorf Science Curriculum of Papa

Papa wish Nana could study in nature way, which connected with the earth, the waters, and the mountains, those nature elements, will be the text in the curriculum. The knowledge comes out interrelated in the world we encountered and sensed by human, especially by their familiar class teacher. Through the teacher's understanding of the world, let students can absorb not only the knowledge but also the absolute floating feeling between the environments. Teacher transit into the curriculum, which is just unique for that place and that moment, and that are all from the teacher's realize and experiences by themselves not from guide line. Not like the textbooks from MOE could use any places and any classrooms. Papa feels if just fallow the textbook it will ruin the passion between man and nature, so that how children can conscious what kind of environments and real aura around them.

In addition, awe to the nature in Waldorf science curriculum is also Papa cherished. As an engineer and work with science, Papa was an atheist before he read the Steiner's book which talk about spiritual world. Although Mama is a Buddhist for long time, and tried to share the Buddhist Scripture to Papa as well. Papa never believe there will be another world in reality before. One of the reason is it's not easy to understand in the Buddhist Scripture, another reason is he studied and works in science field. To see is to believe. It's a little bit ridiculous to believe that there will be a Spiritual world around us in Papa's opinion before. When he research in the book from Steiner, Papa could follow what his writing about the spirit world than before. Because Papa found that Steiner use science methods to proof and introduce the spiritual world, that is his familiar way to realize the truth. That also the reason he has such a strong willing to transfer Nana to study in

Waldorf School devotionally. He believes the elements and the viewpoints in Waldorf science curriculum will broaden Nana's eyes of the world.

CONCLUSION

Recalling Papa's past life, the environments of Taiwan is so natural at that time than Now. Even though the resources of modern life living and education is not as good as present day. Before the time of economic takeoff in Taiwan, people can breath with nature's rhythm in daily life easily. But Taiwan has been catch up with the advanced countries hardly for decades. Even now, we still have to face the competitions within globalization. The result is we want to catch the goal and make money as soon as possible. Everything is going to efficiently, including the science education. Our children read lots of science books, if their parents have ability to support them. We follow up the advance science as fast as we could as well, in order to catch up the level of the western countries. That also is one of the reasons why we develop the OEM of electronic industry. The results of cultivate fast and look forward harvest fast let us lost the aesthetic in the process. Have we gained much more than we lost? We win the reputations in the international exams over the world, but lost the children's motivations and interests in science field. We come after the modern science and worship the high technology, but lose our nature environments and the relationship to connect to the essence of nature.

As Papa's words, he believes that we need the people who can devote themselves to the specialize fields which are their interests in Hsinchu Science Park or anywhere in Taiwan in the future. Our science education has to involve in the feelings within in what science really is. So that children in the future could use their human abilities to explore the outer world and the inner world both. Just like our ancestors realized the relations to the nature, which is exactly as Waldorf education try to develop the awe and get know of the whole nature. That will be a priceless and new exportation of this technology island.
